Preface

Disaster research is relatively a recent subject which has brought together a large number of varied stakeholders such as communities, technology, governance, law, and media in constant discourse on mitigating and preventing disasters. International organizations remain in constant melee for their role in mitigating disasters and their ability in resilience building of vulnerable communities. Business organizations fear an irreparable damage to their supply chains and substantial collapse of micro-small and medium units. Law schools are making attempts to put together new courses which could address key concerns and points of law in a disaster. The terrain of disaster studies appears to be a market place for a variety of disciplines indulging in trade-offs for their dominant status. Notwithstanding a very meaningful research being carried out in every discipline on disasters, a researcher may be at a loss to access it due to deep silos in which disciplines functioned. This provoked a need to break through anachronistic compartmentalization of research and make an effort to explore a fundamental epistemic idea which defines disaster studies. The *International Handbook of Disaster Research* is a single platform which puts together, classifies, and systematizes research on disasters in mainstream disciplines and spawns a transdisciplinary mindset.

The year 2004 has been a turning point in disaster research. A ghost suddenly wakes up from the cracking womb of the ocean as if in a fit of rage turns the world topsy-turvy, washing away 227,898 people and a much larger number of animals. The unforgiving gruesome weaponry of this ghost named Tsunami were the gigantic black waves threateningly rushing toward the land in its clean-up operation like the municipal demolition drives. No one had ever seen or read in history anything about such a macabre event. Humanity sat paralyzed with the jolt of realizations sequentially unfolding before it one by one. First was neglect of earth's carrying capacity, second was irresponsible and corrupt governance, and third was disproportionate political leaning toward vote bank politics rather than synergy for building habitats more resilient and safer places for all species to live and prosper in peace and sustainable abundance. Even if one cannot stop disasters from occurring, one could appreciate and enforce natural laws of seismic activity, forests as green shields, and carrying capacity of land for human habitations to draw reasonable limits to growth and development around earth's fragile regions.

This handbook draws upon social history of technology which has been a great support not only in bringing out authentic data during a disaster, but it also generates open debates against a standard argument of a scheming wolf in the benign state that it is an “Act of God.” Transparency starts from the manner technology and businesses advance since the year 2000. The new Internet technology expanded to social media and subsequently brought a boom in tourism industry with online travel and flight planners. The Trip Advisor and Expedia.com as by-products of the new millennia moved large number of tourists across countries. By 2004, the Facebook social network as introduced by Mark Zuckerberg brought maddening online traffic for sharing photos about travel scenes and sites. These clueless people celebrating Christmas and New Year holidays far away from their homes were suddenly seized by an unrecognizable Tsunami. This Tsunami caused by an earthquake of magnitude 9.1 at the ocean floor of a small island Sumatra in Indonesia was unprecedented and millions of heartrending images were circulated by those who were lucky enough at ground zero to survive or call for help. Time had come that people would not need governments to tell them what it was not, but data were with people to decide what is not an “Act of God.” Transparency, accountability, tortious liability, and performance evaluation had always pricked governance studies, but in disaster studies, they were not seated as sermon monks but as deadly Tsunamis taking Suo Moto action against those who arbitrarily capture riverbed, coasts, and forests and build dream castles over prohibitive fragile land and mountains! Climate change is a treasury alert for disaster managers. Life is in a countdown within a midnight library of equity, fairness, and human rights, and one must be prepared to answer the question “who would live when not everyone can live?”

The handbook has been a team work of some of the best research directors as section experts. This team was not built in a day to undertake this handbook project. We had all been working together for many years, especially since the Himalayan region’s fragility started emerging in repeated eruptions in forms of floods, landslides, and glacial lake outbursts. By virtue of being leaders in their respective disciplinary research, these section experts have been globally acknowledged as trendsetters for many new and refreshing ideas incorporated in this handbook. These experts coming as ground administrators, social scientists, environmental experts, and technologists started converging on the imminent dangers embedded within policy formulation and implementation processes of governments. Media played a phenomenal role when it brought empirical ground surveys faster than the disaster management authorities. All of these scholarly authors and researchers came together to produce this handbook with a three-pronged mission: disaster research should remain transdisciplinary, it should be equitable, and governments should amend laws to facilitate resilience building against disasters. Many lessons taught during the Covid-19 pandemic have been addressed in the handbook.

The handbook starts with a part on Policy Implementation and Best Practices which is treated as a key concern of disaster research and a gateway to many more insights in disaster management policies. In handling this section, the NAPSIPAG (Network of Asia Pacific Schools and Institutes of Public Administration and Governance) experience of cross-cultural best practices simplified a rather complex

implementation research to a sequential response of an understandable inductive logic. The second part on Emerging Technologies and Innovative Applications of AI in DRR is guided by gleaming insights from Dr. Ferda Ofli and Dr. Mohammad Imran from the Qatar Computing Research Institute (QCRI) of Hamad Bin Khalifa University (HBKU). A comparative picture on technology implantations and classification emerges with these experts who brought their enormously deep and discursive South and West Asian experience to the task. The third part on GIS and Geospatial Studies is led by Prof. Chandan Ghosh. A scholar of a very long research experience in this area, he has been a keen editor for getting the right methodologies to serve this section. The fourth part on Institutions and Governance became a mission driven task for a legendary civil servant from India's so called God's own country, the State of Kerala. Since she had been the first Chief Secretary to create country's first disaster management authority in a state, her focus on authentic and balanced analysis without bureaucracy bashing turned a reservoir of knowledge for the handbook. The fifth part on Smart Cities and Technological Innovations for Disaster Management was initiated by Brigitte Lasry, a subject leader from UNESCO led NETEXPLO-International University Network at Paris. With her coordination and co-working with a number of world's best smart city scholars and also editing books on the theme, her vision was wider and more reasonable toward challenges of a smart city. I had to take over at a later stage as Brigitte's tenure at her institution got over. The sixth part on Media and Communication has involved Prof. Jaishri Jethwaney, one of the most vibrant and communicative scholar, on mass media, advertising, and politics. Her task was tough as media people generally do not translate their ground zero experience into scholarly papers. Nonetheless, her communicative skills and online capacity enhancement during many seminars organized by our section editors recharged remote media scholars in writing and sharing their understanding and experience. The seventh part on the Sociology of Disasters is again a gist of a deeply insightful mind of Prof. Siri Hettige from the University of Colombo, Sri Lanka. It was no doubt an ordeal to organize, select, and prioritize a minuscule from heaps of versatile and striking ideas on his table, but his reliance on the art of just elimination made it possible. The eighth part on Disaster Law has been a brainchild of Gabrielle Emery and together we handled this section. She was head of the Disaster Law division at The International Federation of Red Cross and Red Crescent Societies (IFRC). She subsequently moved to UNDRR but continued to guide us through the section and its key focus areas which were in need for more research. The ninth part on International Law and Collaboration received brilliant analytical support from Prof. Mohammad Ekramul Haque from the Law faculty of Dhaka University. His training and experience in international humanitarian and disaster law attracted some meaningful papers of immense value for researchers. The tenth part on Administrative Initiatives and Best Practices has been effectively addressed by Prof. Lalitha S. Fernando from the University of Sri Jayewardenepura, Sri Lanka. Picking up appropriate and application-based methodologies from Public Administration, this part will be of immense value to policy formulators and scholars in the discipline. The eleventh part on Cities and Urban Governance has been led by a very experienced city manager and planner

from Japan, Prof. Kiyoshi Murakami from Tohoku University. As a Chief Executive Officer and strategy advisor at the City of Rikuzentakata, he provided his most practical and application-oriented research support to the authors. The twelfth and the last part on Business During Disasters has been directed and edited by Prof. Huong Ha from the faculty of Business and Law, University of Newcastle, Singapore. As a very keen and dedicated researcher on the subject of business during disasters and especially during the recent pandemic, her holistic and equity-based approach enriched papers in the section. All section experts have tirelessly worked together during the pandemic to give the reader one of the most unmatched and substantially complete experience rarely available elsewhere. The sumptuousness and intelligibility that this handbook offers to those looking for suitable inputs to research and policy making may valiantly fall back on its framework of research for different sections.

The team that produced this handbook also included some of the most brilliant publication managers from Springer Nature, who knew the art and sophistication of managing ideas, time, and content. From the time that Dr. Mokshika Gaur, Senior Editor from Singapore, floated this idea of a handbook at my office room at JNU, the work appeared too ambitious. She politely persevered and subsequently brought together Director Dr. William Achauer, from Singapore Office, and Editor Ms. Nupoor Singh, from Delhi-Mumbai Office, to motivate and discuss the objective and a tentative plan for the handbook. The work still seemed incredible, formidable, and challenging due to my disbelief if there really was enough research on disasters and also authors willing to share it in a handbook. Nupoor and Mokshika were so excited to see the work picking up that its worthy of mention here that they did not disconnect with me even for an hour in the last two years. Gradually, as work expanded, two extremely brilliant and knowledgeable team members pitched in. Dr. Gaurika Chugh, Assistant Professor and an academic researcher with a long experience at JNU, joined in as a Managing Editor, and soon after Ms. S. Shameem Aysha joined in as a Publication Manager. For the last year and a half, the first call and the first beep on my mobile were work reminders from them. This definitely speaks volumes of their dedication and commitment to work. As if it was ordained, two delightful journeys concluded almost together, the handbook and Aysha's final month of pregnancy. The whole team of experts and editorial board share her joy and wish her a very good future.

Three points define this handbook: appropriate algorithm for research framework in technology usage, team spirit in decision making, and finally a convergence of transdisciplinarity in content and methodology of research. It can not only help in the enrichment and evolution of research and policy making in disaster mitigation and resilience building but also suggest the value of team work to those still stagnating in their disciplinary and professional silos. This is a handbook which would live through generations in libraries.

New Delhi, India
September 2023

Amita Singh

Acknowledgment

With special thanks to the handbook team of section experts, editorial board, and the authors who have sailed together through the tough times of the pandemic.

Contents

Volume 1

About the Editor

Amita Singh is President of NDRG, an Asia Pacific (NAPSIPAG) Disaster Research Group, a Senior Professorial Fellow at the Institute of Social Sciences, New Delhi, and Senior Distinguished Visiting Professor at the National University of Juridical Sciences, Kolkata. She superannuated from the Centre for the Study of Law and Governance at Jawaharlal Nehru University in 2020 where she has also been the Founder Chairperson of the Special Centre for Disaster Research. She is member of the International Network for Disaster Studies and serves on the Board of many key international journals on disaster studies.

Prof. Singh is trained in Political Science, Public Administration, and Law (MA, LLB, PhD). She is widely known for her grassroots transdisciplinary governance research with research collaborations spanning through many universities and government departments in India, South Asia, USA, and Australia. Her work on implementation studies and best practices in community initiatives started in 2006 at the Hawke Centre of the University of South Australia, Adelaide. She further collaborated with the Global Innovators Network, at the Kennedy School, Harvard University and IT for Women Initiative at Maryland University Baltimore (2004–2006). She has been awarded the Australia-India Council (2006) and Australian Government-Monash Fellowship (2016). In 2016–2017, she was Visiting Professor at the American University at Washington DC. She has also served as a member of the Jury and Advisory Board of UNESCO-Netexplo International University at Paris and has presented her study of NGO-led best practices at the UN General Assembly. She has supervised a large number of Ph.D. students who

adorn prestigious positions in academics and in administration.

She has authored and edited many books and several national and international research papers besides being the “Series Editor” for Palgrave-Macmillan’s Global South Series on Disaster Management with five books in a row. She has authored some important fact-finding reports (Uttarakhand 2013 and Kerala 2018) on her collaborative empirical research related to disasters and administrative preparedness. These reports have served as lighthouses to policy makers and judiciary. As an advocate of animals and environment, she has shared her experience in some daily newspapers such as the *Deccan Herald*, *Hindustan Times*, and *The Daily Guardian* (Columnist).

Her contribution to community research has been duly acknowledged in the awards bestowed upon her, i.e., Delhi’s “Public Service Award,” NALSA’s “Social Justice Award,” “Millennium Award for Women in Public Services,” and “e-Governance Award.” She also received the 2014 Bangladesh’s National Award “Nawab Bahadur Syed Nawab Ali Chowdhury National Award” in Dhaka. Prof. Singh is an ardent campaigner for habitat protection and rights of all species to share planet earth justifiably without violence.

Abstract

The objective of this International Handbook of Disaster Research is primarily twofold: first to enable Asian perspectives generate a surge of ideas which correlate, diversify, or question a firmly entrenched western determinism or American exceptionalism in disaster studies. Determinism is characteristic of an approach which suggests that one is a captive of a particular way of thinking and their responses to different situations are quite the same as could be anticipated. Seymour Martin Lipset in his work *American Exceptionalism: A Double Edged Sword* (1997) has explained it in detail. One could pick up any work on disaster management prepared in the last decade to see that Asian narratives are rare entries even though their experience with disasters is much more varied, deep, and diversified in social, ecological, and community-centered strategies. Second objective is to formulate some kind of a holistic and all-encompassing transdisciplinarity among multifaceted studies in disaster management which have so far remained confined quite ineffectively yet arrogantly within their exclusive

silos. Once transdisciplinary interaction or a dialogue begins, disaster management would no more remain a meandering dervish (A Sufi who is always in search of a universal spirit) or an epicurean technological hedonist (a pleasure seeking, money earning glorified scholar). Keeping the two objectives ahead of the plan for this handbook, there are 12 parts led by transdisciplinary expert scholars who have worked together as a team and generated synergy within the sections for an effective disaster management for planet earth like a Noah's Arc for us. The message from this work is that no one can do it alone and decisions in disaster management should follow a democratic, non-hierarchical, and communicative spirit with an understanding about the limitations of planet Earth rushing toward its concluding detonation.

Anthropocene · Other-humans · Adaptation · Climate change

A Guide to Better Research in Disaster Management

This International Handbook of Disaster Research is planned with the objective of disseminating information from across the world on varieties of disasters, vulnerabilities of habitats, and governance strategies. Research strengthens decision making and brings clarity on accountability. It is an indispensable requirement for connecting grassroot communities with their municipal authorities, Wards, and Panchayats (grassroot institutions of governance in South Asian region). Writings in this handbook have attempted to cover regions of persistent disasters, which have rarely found a place in Western Euro-centric literature on disasters. This makes the handbook unique as a compilation of voices from the remotest and most ignored areas of the world especially Asian region and may provide a new direction to ongoing global research on disasters. Notwithstanding its volume and outreach to the non-Western world, emphasis has nonetheless been comparative and solution oriented. Decision makers may re-strategize their policies on disaster management with ideas on new technology for disasters, its limitations, databases, information sharing, participatory governance, institutional responsibility, legal compliance, and role of media in a changing world. Currently, planet earth is more vulnerable to vagaries of climate change and increasing devastation that few can control with available tools. Voices from grassroot communities have ensured that this handbook can definitely be a fundamental base book for anyone working or undertaking research studies on disasters.

What are the five elements of disaster research? Fig.1

Provides Space for Non-Western Narratives and Strategies for Disaster Management

This handbook covers global studies, yet the focus is on Asia-Pacific and specifically the Hindu Kush-Himalayan (HKH) region, which encompasses an area of mountains in eight countries of Afghanistan, Bangladesh, Bhutan, China, India, Myanmar, Nepal, and Pakistan. A study (Matin & Islam, 2021) assessed the decision-making processes at the institutional level in four countries – Afghanistan, Bangladesh, Nepal, and Pakistan on their institutional capability on a single important ingredient of disaster management, which is usage and sharing of geospatial information. It found an immense lack of data and resources such as hardware, software, human, and institutional. Besides a need for strengthening decision-making processes the study raised an important point on the for partnerships to reduce vulnerabilities and achieve resilience. As it appeared from studies across Asia Pacific that deficient institutional capability notwithstanding improved space research and remote sensing reflected gaps in policy frameworks of most countries. In addressing hydrometeorological and environmental challenges advanced geospatial tools are needed in disaster management. Much of this effort needs governance, which does advance planning, preparedness, land resource mapping, and data sharing tools for dissemination to all agencies equitably.

The handbook becomes extremely important for current times, which are encountering deep ethnic, religious, and national divides combined with climate and

war-led migration. Governance institutions and law stand as a small David before the mighty Goliath. Governance and data sharing may turn out to be one of the most glaring challenges to new regional alliances such as IORA (The organization was first established as Indian Ocean Rim Initiative in Mauritius on March 1995 and formally launched in 1997 by the conclusion of a multilateral treaty known as the Charter of the Indian Ocean Rim Association for Regional Co-operation.), G-20 (The **G20 or Group of 20** is an intergovernmental forum comprising 19 countries and the European Union (EU). It works to address major issues related to the global economy, such as international financial stability, climate change mitigation, and sustainable development.^[3]), BRICS (**BRICS** is an acronym for five leading emerging economies: Brazil, Russia, India, China, and South Africa. The first four were initially grouped as “BRIC” (or “the BRICs”) in 2001 by Goldman Sachs economist Jim O’Neill, who coined the term to describe fast-growing economies that would collectively dominate the global economy by 2050;^[1] South Africa was added in 2010), BIMSTEC (The **Bay of Bengal Initiative for Multi-Sectoral Technical and Economic Cooperation(BIMSTEC)** is an international organization of seven South Asian and Southeast Asian nations, housing 1.73 billion people and having a combined gross domestic product of US\$4.4 trillion (2022)), the Mekong-Ganga Cooperation (The Mekong-Ganga Cooperation (MGC) is an initiative by six countries – India and five ASEAN countries, namely, Cambodia, Lao PDR, Myanmar, Thailand, and Vietnam for cooperation in tourism, culture, education, as well as transport and communications. It was launched in 2000 at Vientiane, Lao PDR), etc., which have taken over older regional pacts such as OPEC (Organization of the Petroleum Exporting Countries (OPEC) is an intergovernmental organization of 13 nations, founded in 1960 in Baghdad by the first five members (Iran, Iraq, Kuwait, Saudi Arabia, Venezuela), and headquartered since 1965 in Vienna), SAARC (The South Asian Association for Regional Cooperation (SAARC) is the regional international organization and geopolitical union of nations in South Asia since 2006) and OECD (The Organisation for Economic Co-operation and Development (OECD) is an intergovernmental economic organization with 35 member countries, founded in 1960 to stimulate economic progress and world trade) with their embedded challenges. How far would they work and synchronize country-based efforts and form disaster resilience through healthy and honest partnerships is yet to be seen. Their collective march toward targets set for the Sustainable Development Goals by 2030 has sensitized them to a need for integrating disaster management in developmental planning and programs. Implementation remains a challenge of priorities as brought out in papers.

A Holistic Framework of the Handbook

The handbook covers 12 key sections steered by experts who combine years of experience with their academic leadership and ground research. For the convenience of readers effort has been made to draw some technical boundaries among these sections but considering the nature of disasters there exists sufficient overlapping

and highlighting of common concerns. The section experts have presented frames of their ideas in their introductory chapter, which unfolds into regional and area-based concerns and solutions in contributions by authors. The following parts constitute this handbook;

1. Policy Implementation and Best Practices
 2. Emerging Technologies and Innovative Applications of AI in DR
 3. GIS and Geospatial Studies.
 4. Institutions and Governance
 5. Smart Cities and Technological Innovations for Disaster Management
 6. Media and Communication
 7. Sociology of Disasters
 8. Disaster Law
 9. International Law and Collaboration During Disasters
 10. Administrative Initiatives and Best Practices
 11. Cities and Urban Governance
 12. Business during Disasters
-

Synchronizing International Framework with National and Local

Certain important issues have been flagged in all chapters, which synchronize well with the objectives of three international frameworks and the critical narratives, which follow in national, local, and regional capacity building questions. These three international frameworks are the;

- Hyogo Framework for Action (2005–2015) for identification of risk on a priority and staying prepared to prevent disasters. As a knee jerk instant response to the 2004 Tsunami that shook governments across the world Hyogo gave a skeletal frame over which much had to be designed to obtain a clear national and global strategy for implementation. Hyogo Declaration was nonetheless a clarion call to wake up national governments and they responded with their country-specific disaster management acts. This brought tremendous transformation in perspectives on community research and developmental initiatives.
- Sendai Framework (2015–2030) that goes beyond “risk identification” to a more mature and substantive requirement of governance to manage disasters. It emphasized State responsibility alongside that of local bodies, private sector, and other stakeholders. The key objective of this governance as for any other sectoral area is to “Build Back Better” in recovery, rehabilitation, and reconstruction. So issues of Constitutional democracy, human rights, and participatory decision making became as important as implantation and adoption of technology for disaster management.
- Sustainable Development Goals (SDG 2015–2030), which alerted governments on reiterating Brundtland (Norwegian Prime Minister Gro Harlem Brundtland prepared a report as Chair of World Commission of Environment and

Development in 1987, which is called the **Brundtland Report, Our Common Future**. This report introduced the concept of sustainable development in the midst of environmental degradation and concern for social equity and economic growth) Commission's invocation and incantation of sustainability as a breath of life at its last gasp. Consequently, all developmental initiatives were rendered lifeless in the absence of their evaluation on a scale of damage and losses to environment. SDGs are understood as a shared blueprint on peace and prosperity in the world.

Ideas Highlighted in Sections

Authors have their country-specific disaster management acts as their primary light house as they take it forward to address management issues. A central coordinating authority has come up in every country after the coming of country-specific disaster management acts, yet during pandemic management (2020–2022) a phenomenal lack of coordination was seen. This existed not just within the country that impacted the functioning of national agencies but affected many other cross-border operations such as international rescue, airport-railway-bus passages, visa and custom support, across the border trade, rights of aid-workers, and emergency equipment transportation. For example, South Asian countries which are largely located on a single land mass and could have done much better in coordinating toward cost-effective measures were not even able to coordinate on a minimal scale despite an available framework of action in SAARC Agreement on Rapid Response to Natural Disasters (SARRND 2011).

There is lack of policies, legal frameworks, and mandates to produce, archive, and share data. This is combined with many institutional issues in technology and data sharing leading to replicative production of the same data by different agencies. Geospatial technologies are used in different capacities, intentions, and objectives, which obstruct institutional coordination and understanding on sharing data. Recently, in 2021, Brazil, Russia, India, China, and South Africa (BRICS) initiated cooperation in this direction when it signed an agreement for cooperation in remote sensing satellite data sharing as brought out by Indian Space Research Organisation (ISRO), which had already been sharing data information bilaterally with South Asian countries. Indian Remote Sensing Satellites shared data with Sri Lanka during tsunami and with Bangladesh during the cyclone SIDR. Sharing data has, to an extent, been taking place with Nepal and Maldives too. This sharing is highly inadequate as individual SAARC countries with an exception of India have woefully lacked in utilizing space-based assets. Most regional groups of countries need a much articulated cooperation on meteorology, hydrology, oceanography, seismology, and atmospheric studies yet dedicated regional satellites continue to remain marginal concerns in disaster prevention. The GSAT-09 satellite launch in India is expected to bring greater cooperation and coordination with neighbors in water conservation, weather forecasting, and early warning on disasters.

The handbook recognizes the fact that the world is more turbulent than what it was at the beginning of this millennium. International law is being broken with impunity and nature remains a victim to demands that go beyond earth's carrying capacity. Climate change, agricultural adaptation, medium- and small-scale industries, urban management, smart cities, water bodies, habitat destruction, migration, and human rights are new concerns, which have been addressed in the handbook. The developer led cities had been an acceptable norm since the beginning of globalization in early nineties. However, this trend changed as urbanization became an extended project of smart cities despite the pit holes of governance deficits. So, key issues of governance, such as democracy (Singh, 2021), accountability, transparency, and participatory decision making have been investigated in disaster management initiatives. Repeated incidence of landslides, forest fires, glacial lake outburst, and floods have insisted a thorough environment impact assessment as a precondition to approving any project anywhere but more stringently in coastal and hill areas, which are sentinels against climate-led destruction that is defining contemporary era now being referred to as a metaphor "Anthropocene" (The Greek *Anthropocene* means the "recent age of man.") This term was coined by American biologist Eugene Stoermer in 1980s, but gained global attention when a number of geologic science forums proposed to treat it as a formal geological interval in which human activity have had a substantial negative impact on planet earth). Disasters are by-products of this era.

It is in this Anthropocene era that the processes of law ought to be redesigned with stronger norms of equity, justice, inclusive governance, and unhindered institutional and individual tortious liability. Decisions on environmentally prohibitive activities undertaken in defiance of law demands uncompromising political leadership. The section on disaster law highlights a scenario based on enormous experience of advocates and cause lawyers in courts, legal experts, and international experience in disaster philanthropy of the International Federation of Red Cross and Red Crescent Societies (IFRC). This new area of law is deeply embedded into saving lives in disasters, reducing suffering due to disasters, and upholding human dignity for victims of disasters. Disaster Law resonates these three human demands in the Court of Law.

The section on Media in the handbook indicates a new world, which has jingled into a boundaryless terrain through the World Wide Web. Media shapes public opinion much faster than any other technology or human design today. It is rather difficult to say if the 360 degree and 24/7 news channels and social media (Twitter, Whatsapp, Facebook, Instagram or the new entries like Zoom, Vice, or Buzzfeed) alongside the rather diminishing daily newspapers continue to validate a coherent, reliable information about disasters (Franks, 2013) to render disasters more "observable and knowable" (Cottle, 2009) or does it portray a calamity, which has no precedence, an Act of God, which encourages and deflects government action to silently legitimize deaths and devastations in public imagery. Risk communication is a specialized field today starting with newsroom action to investigate whatever happened, who was affected, and who may be responsible sets a trend for government and peoples' debates (Greenberg & Scanlon, 2016). The role of disaster journalism in an era of global networking, capital flows, and transnational satellite

media creates a logic that influences people profoundly and shapes an understanding about a disaster. This may portray governance deficits, environmental neglect, a multinational project, lifestyle changes, corruption, and climate change.

Animals or the “other humans” are the worst victims of inequitable and unjust disaster management laws (Coll, 2013). Equity is nothing but morality, fairness, and good conscience yet disaster laws ignore the presence of these other humans (animals). As a result, these other humans are left behind to be washed off in floods, be burnt to death in forest fires, and be buried under rocks in landslides. Governments around the world have not adequately delivered equity and justice for animals in their country’s disaster management acts or even in their national disaster management plans if any. A standard legal principle suggests that, “no relief (in torts) could be given if the demand arises in connection with one’s own tortious acts” or in Latin, “Ex turpi causa non oritur actio” (from a dishonorable cause an action does not arise). So, if men are causing most disasters today due to anti-environment developmental policies, generate toxic pollution in water and over land, deforest green areas and release more CFCs (dishonorable act) to cause climate change, does man deserve relief? By this argument, animals are innocent victims of human’s dishonorable acts (Singh, 2022) and should legitimately be given relief. Kashmir floods of 2014 and Kerala floods of 2018 washed away more than 6.5 lac and 4 lac houses, pets, poultry, and livestocks, respectively. The Australian forest fires killed and displaced more than 3 billion animals from June 2019 to February 2020 (Vernick, 2020).

The much televised heartbreaking Snowball incident from Hurricane Katrina in 2005 drew phenomenal public attention. A 9-year old boy refused to leave behind his small dog Snowball, and telecasting of such a tragic episode on television and news media sites generated such a moral outrage that forced American government to revisit their rescue policy on a priority. The US Congress immediately brought the historic Pet Evacuation and Transportation Standards Act (PETSA) 2006. This Act amends the Robert T. Stafford Disaster Relief and Emergency Assistance Act and authorizes the Federal Emergency Management Agency (FEMA), “to ensure that state and local emergency preparedness operational plans address the needs of individuals with household pets and service animals prior to, during, and following a major disaster or emergency” (PETSA, 2006).

This stupendous and much awaited initiative even with its anthropocentric leanings for pets and service animals only (not stray and homeless) was indicative of change in the manner that cities were governed. It pushed badly governed states like Louisiana into an indispensability of sensitive animal management policies such as the Animal Birth Control (ABC) to stay prepared. Ironically, this ABC should have been part of all Smart Cities yet it is missing out in most other countries including India. A few forward steps that have been taken up in the 2016 and 2019 National Disaster Management Plans are still not implemented in India since implementation depends much on efficient and participatory State governance systems. The handbook carries this inclusive sentiment across all sectional themes as an important ingredient of disaster management research and policies.

Conclusion

This handbook on Disaster Research is a mine of ideas from the developed and the developing world on their perceptions, strategies, governance, and legal frameworks that help to create an enabling environment for disaster management. It helps to identify distortions occurring in disaster studies due to technology-centric approaches and suggests solutions to balance them through practitioner's experience with public administration, governance, and policy sciences. International humanitarian law and media studies provide flywheels to the implementation of disaster management toward an inclusive, equitable, just, ethical, and holistic policy framework. This book has interrogated some of the major contemporary narratives in each section and will prove to be a one stop shop for decision makers, researchers, policy makers, academia, and students.

Abstract

Policy implementation in disaster management is one of the most sensitive displays of the state capacity in governance. Owing to its wider broadcast across media, the success or failure of implementation becomes the face of a particular disaster. For example, Hurricane Katrina carried the reputation of Louisiana State's corrupt government, the Kedarnath disaster (2013 India) apathetic governance, the Kerala Floods (India 2018) ill-coordinated dam management, etc. It brings together on the table deficits of administrative, political, and technological decision making and highlights social vulnerability and access to justice. The legal and governance framework is treated as a causative reference point of implementation. This framework represents official capacity to address citizen's concerns. It also displays structural strength when faced with media trial rooms at a time when disaster strikes and multiple questions arise around government's

planning processes, early warning technology and access of information to citizens. Despite its crucial indispensability in making policies effective, implementation remains today what it was in the early 1970s, when Erwin Hargrove ([1975](#)) referred to implementation studies as the *missing link* of policy sciences.

Communitarian · Digitizations · Expediency · Innovation

Introduction

The “Smart,” “Unsmart,” or “Smart Enough” Cities in Disaster Management

A Few Perceptive Findings Define the Universe of Implementation

First, the end results of all forms of implementation are always unanticipated and unintended. As Margetts et al. ([2010](#)) write on modern organizations as functional embodiments of modern science and business practice, yet they come to produce outcomes that are so far away from what was apparently anticipated or intended ([Potoski, 2001](#)). The Vietnam War (1968) and later the Chernobyl nuclear leak (1986), and even the disintegration of the Soviet Union explain how even the most scientifically and evidence-based planning can go awry and be shockingly different than the original purpose of its policy.

Second, the human capacity to foresee is highly limited. R. K. Merton, the sociologist of the early twentieth century, established this belief quite scientifically in his work, *The Unanticipated Consequences of Purposive Social Action* ([1936](#)) that the social change expected of a policy may not be so. He explained the nature of “conduct,” which comes out of “purposive action.” Conduct, being part of a purpose, can make rational choices between various alternatives, but “behavior,” which an individual carries, is a response to stimulation from one’s environment, one’s group, or a particular species. Therefore, this difference between “conduct” and “behavior” ([Ostrom, 1998](#)) explains most deviations and deflections that occur during the implementation of policies.

Third, there are various interests that influence and carry forward or impede implementation on issues of substantive democracy. Constitutionalism alone, as perceived, may not be a guiding light to implementation. James M. Buchanan and Gordon Tullock, in their epoch-making work *The Calculus of Consent* ([1962](#), p. 361) and Mancur Olson’s *Logic of Collective Action* ([1965](#)), started looking into various interests that control democracy and political economy. There were strong influences on policies related to taxation, program expenditures, budgets, and the political process. From economics to public administration, many cross currents of theories emerged to explain implementation. O’Toole ([2000](#)) argued that there is a

world of viable theoretical constructs (e.g., principal–agent, rational choice, and game theories) upon which implementation can draw during changing times, while encountering a variety of interests. The continuation of disasters in some areas of every country as opposed to quick action in certain others may reveal politics of vote bank, race, caste, and religion.

Fourth, implementation mostly provokes issues of justice, fair distribution, and equity. For example, the Coastal Zone Management Laws in every country have incited local communities, fisherfolks, land and water usage laws arrived as projects, and developmental permits were to be issued by local authorities. Thus, a trade-off between laws and projects may defeat the purpose of laws and force amendments to give relief to the interests of powerful projects. In India, the 1991 Coastal Zone Management Regulations have been amended 25 times to give relief to projects that were approved over fragile coastal zones without adequate clearance and environmental impact assessment (Aggarwal, 2018). The situation is not much different in a highly developed country such as the USA. Schoenbaum and Rosenberg (1976, p. 9) observed that “this lack of enforceability is the Achilles heel of North Carolina’s emerging coastal zone management program.” They suggested that unless it is corrected, this weakness will undermine its effectiveness, not just in North Carolina, which they have studied, but in all other States as well.

Fifth, implementation always fails to reach out to the last mile, i.e., the people most affected by a striking disaster. This last mile therefore becomes a critical stage of humanitarian aid provision to the people suffering most who are trapped in the most unreachable, remotest areas. Although delivering technologies such as drones and artificial intelligence-driven vehicles have greatly transformed the last-mile delivery, a pre-existing lack of support infrastructure, such as transportation road-blocks, lack of medicines and ambulances, limited finance, which is unable to manage delivery costs, and a lack of urban freight combine to leave the last mile largely unattended. On top of this, the same government that neglected the city infrastructure and remained unaccountable and corrupt with impunity multiply difficulties in reaching out to the last mile (Balci et al., 2008).

Last, implementation at all levels and all stages requires immense and intricate coordination between many agencies and departments. In disaster management policies, this coordination requirement is relatively more complex and forceful than in other policies owing to its transdisciplinary nature. During the recent COVID-19 pandemic, most countries realized that managing a disaster is not analogous to managing a ritual policy implementation, but it stands apart because of its continuous coordination between government agencies, nongovernmental organizations, corporates, vulnerable communities, international organizations, aid providers, equipment suppliers, technology, media, and rescue teams. To understand it better, a study of implementation challenges and need for coordination is well documented in a paper by Singh (2020, p. 377). It is for the sake of effective coordination that disaster management in every country requires a brilliant, enlightened, and smart leadership to compensate for many coordination gaps, which are likely to do damage beyond the destruction already caused by a disaster.

Essentials of Implementation

Implementation is one of the earliest problems of policy sciences and remains unresolved today. When Pressman and Wildavsky published their work in 1973, the global recession was at its peak following failures of the UN's first 'Development Decade' of the 1960s. This Development Decade was an outcome of the General Assembly resolution [resolution 1710 (XVI)] on a proposal by the US president which said that problem of newly emerging states was not just hunger but much more. The decolonization process had increased the number of underdeveloped, post-colonial nations in the General Assembly. These new and nascent republics were encountering serious issues of democratic deficits and slippages in implementing their developmental goals. The major drawback of development administration was its implementation, as the "conduct" and "behavior" of both administrators and citizens stood in defiance of the law (de Leon & de Leon, 2001).

In consideration of the above prerequisites of implementing disaster management policies the following requirements stand uncompromised:

1. A legal framework in the form of a statutory Act as its baseline functional necessity.
2. A Central Coordinating Authority such as the National Disaster Management Authority and its subordinate authorities for the States and the District levels.
3. Decentralized governance or decision making related to preparedness against disaster comes the bottom upward.
4. Sustainability as a key attribute of implementation may become a futile policy as disaster managers may not be focused enough to understand or take instructions. Administrative authorities may stop discounting environmental limits set by principles of carrying capacity, inter- and intra-generational equity, and justice.
5. A highly committed and trained regular force such as India's National Disaster Response Force rather than the country's Army, may be deployed to manage disasters.

Implementation Has a Strong Connection to Local Governance

Local governance (Ostrom, 1993, p. 227) is an edifice that brings the first knock to disaster-affected vulnerable communities. It is a repository and a source of knowledge, information, skills and social capital, it balances the "capacity deficits" of government by adding to it cumulative communitarian experience, indigenous skills, and appropriate local science. Owing to the functional visibility of the authorities, local governments also bring greater clarity on issues of accountability, information, damages, and losses brought about by disasters.

The 1990s brought new currents into policy implementation, as new public management approaches and new institutional economics redefined its boundaries. Goggins et al. (1990) reintroduced a study of patterns in behavioral changes across different situations and found modern concepts of game theory or principal-agent

theory meaningful in predicting governments' responses. As this direction of studies advanced, rise of contingency theory could be seen in the works of Richard Matland (1995), Helen Ingram (1990), and Denise Scheberle (1997). Barring Matland, the other two contingency theorists justified more than ever before that no one single centrally directed mega plan can resolve a multifaceted ground contingency. Capacity and trust in local communities are strong and are relatively more readily available. These theorists of the contingency approach find little reason to accept that one shoe fits all situations. The work of de Leon and de Leon (2002) summarized the justification of local governance as the best source of implementing a policy, as it is reflective of communitarian interest rooted in local democracy: "Rather than having a policy imposed by a policy maker who is counselled by select (hardly representative) and narrowly focused interest groups, the potential clientele are proposing a policy that will directly affect them. In short, a bottom-up policy implementation will tend to be more realistic and practical, in that it suggests that the vox populi have a great deal of say about where they are going and how they choose to arrive" (p. 478). The authors further establish that such an approach, which emerges from local communities, will be increasingly democratic and discursive, as opposed to the top-down "command and control" policies. In the final analysis, contextual conditions would dominate an effective implementation of policy. However, the digital era governance, which is rapidly being introduced into the implementation of disaster management policies, is likely to weaken the role of local communities and produce unanticipated consequences of implementation. In the latter part of this chapter, we attempt to analyze this challenge as well, and suggest a few cautious steps in the implementation process.

Digitization of Disaster Management Policy Implementation

Technological implantation and modernization have currently become key drivers for efficiency and speed in implementation. In fact, the Smart City model of disaster management is increasingly designed upon artificial intelligence, machine learning, and the Internet of Things, which tend to define new models of policy implementation in disaster management. In hindsight, this change is simultaneously weakening the important local connection of implementation and returning to the State-centric mega models of implementation. Databases likely to construct the algorithm of disaster management may distort information processing in a manner in which justice and distribution may not be adequately recorded. Subsequently, implementation would again be stuck in the same old unresolved predicament of obtaining unanticipated and unintended outcomes.

The designing of the World Wide Web (www), created by Tim Berners-Lee, has such a phenomenal presence and a hegemonic control of information today that the natural meaning of words and expressions from unstructured natural language is almost lost. One tends to learn the world from text and annotations over the www. Therefore, the internet, which was developed by academics and military computer scientists for military and war management, has become a social innovation

(Margetts et al., 2010, p. 102) for its services to entertainment, governance, banking, transport, and a number of other systems. Therefore, something designed for one purpose is actually working for another purpose bringing unanticipated results. To conclude, the digitization of policy implementation may also not ensure a purposeful achievement of those objectives for which it was originally brought into policy structures.

One would be charmed by the enormity of information available to the user at a single command over the keyboard. Owing to the simplicity of information extraction, the process itself becomes a design embedded in a purposeful act. Coupled with satellite navigation, which fills the universe with various databases of information, the meaning given to a term may depend upon its interpretation. In the end a simple assumption expressed by a local community in one's unadulterated natural language may convey a different meaning at the other end. Therefore, information extraction has become a central point of disaster planning and implementation. Most terms are so highly scientized that only a scientist who knows the real meaning of the terminology or annotation used in the information may know its meaning. Therefore, information processing may discourage community participation because of its complexities. An implementer should first simplify scientific terms, even the ones considered overtly simple such as red, orange, and yellow alerts for floods. A report on the Kerala Floods of 2018 found that most local communities were caught unaware as they did not know what these colored alerts were indicating and the district disaster management authority did not explain these to them in advance. Figure 1 represents the stages of processing information and formulating a program on one's understanding of a problem from the barrage of meanings available on the internet. This complexity of information processing weakens implementation.

Implementation and Political Expediency

Implementation ought to be politically expedient in democracies where governments tend to please their vote banks more often. Defiance of building norms in cities, tree felling over fragile land and hills, construction over water channels, and sand mining of rivers have been repeatedly causing disasters. The Morbi Bridge collapse (India News 2023) in Gujarat, which kill more than 135 people, as was brought out in the five-member SIT Report, or, the illegal construction over a temple stepwell in Indore, the no. 1 smart city of India killing 36 people, were tragedies that could have been averted by timely action by the government.

Implementation is not just getting it done but letting it happen. Although authoritarian governments may believe that "Laws" constitute the strongest whip against noncompliance, in reality it continues to be the weakest stilt in the implementation process. Consistent communication, collaborative drills, and trust building with local communities are basic to implementation as the government benefits. First, the government receives clear first-hand original information from the affected community. Second, participatory approaches make implementation cost effective with the support and collaboration of local communities. Third, a belief is generated to

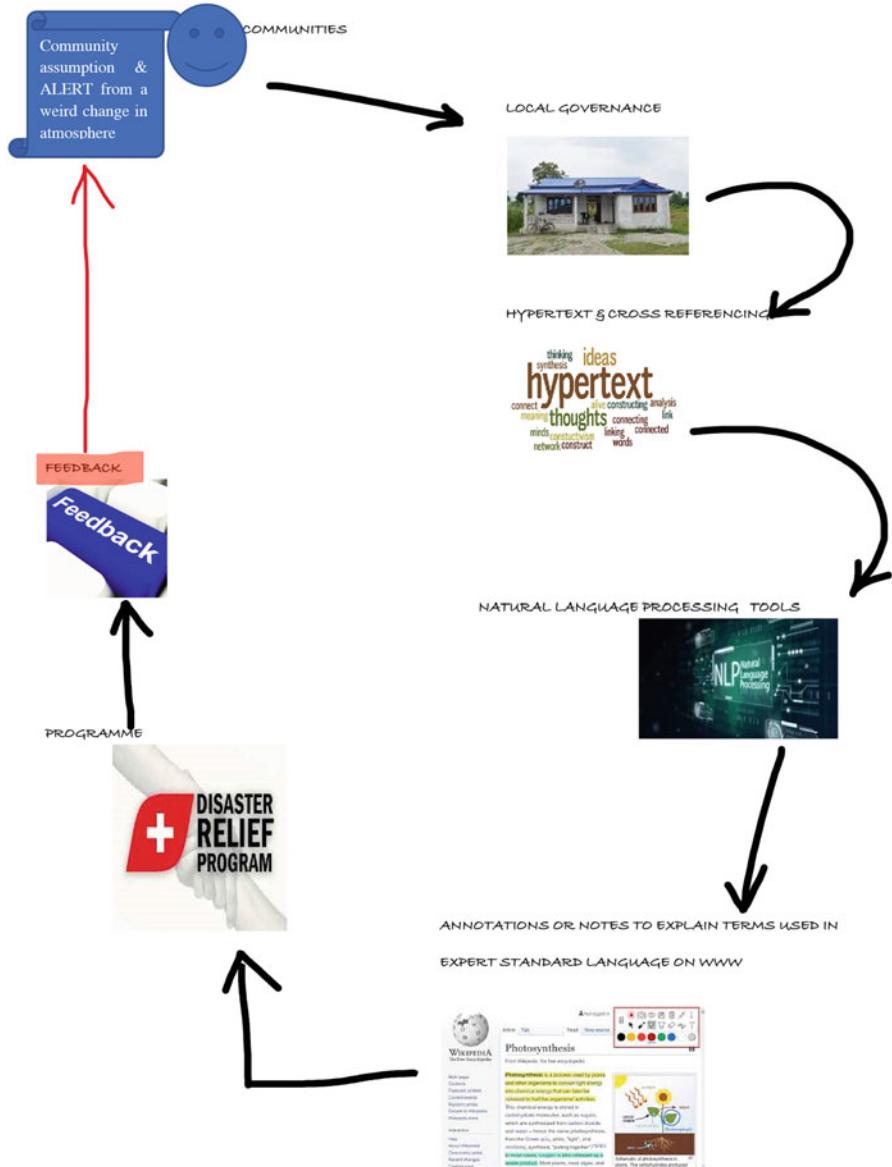

Fig. 1 Stages that process information and formulate a program for implementation in disaster management. (Source: Author)

provide support and trust the success of policy outcomes. Rational choice theorists have warned against political expediencies in implementation processes and have suggested greater dependence on data and logic to achieve rationally sound implementation. Nevertheless, a basic tool kit emerges out of this discussion on

implementation, which may bring greater possibilities of achieving not what often comes about as unanticipated outcomes but anticipated and intended results.

1. **Local communities should be partners** in local decision making on developmental projects in their areas. This includes their role and partnership in environment and social impact assessment-related investigation studies and the protection of whistle blowers on defiance of various laws, corruption that weakens protection against disasters.
2. **Coordination should be strengthened** between the State and local agencies, between rescue forces and evacuation teams, between the State and relief agencies, and various State authorities on the procurement and testing of medical equipment, the essential needs of people.
3. **Pre-emptive planning to avert disasters** affecting the region such as infrastructure, transport, medical support, ambulances, and telecommunication including functional early warning systems. **For other humans (animals) in cities** and rural areas, evacuation routes, food and water storage, and shelters, alongside a continuous and consistent Animal Birth Control program.
4. **International agreements to facilitate relief providers** and aid workers with custom, visa, and movement support. The State should be collaborative and respectful toward vulnerable neighbors trapped in disasters. South Asia's most meaningful agreement on disaster planning and implementation, the South Asian Association for Regional Cooperation Agreement on Rapid Action against Natural Disasters of 2011 is yet to be implemented.
5. **Empowered and trained local governments** to address contingencies of disasters with quick decision making. These local governments should develop and work toward a network of local schools, colleges, universities, and communities to conduct regular drills and training programs in an inclusive manner.

Conclusion

Implementation provides a face to any policy, as not even the best formulated policy can be deemed a success until it is implemented. Disaster prevention policy should be implemented in a manner in which it is able to achieve its intended results. Studies in policy sciences since Pressman and Wildavsky (1972) have suggested ample evidence to demonstrate that policy implementation generally produces unintended and unanticipated results and sometimes serendipity may also explain outcomes of policy implementation as varieties of accidental surprises may emerge unintentionally on many fronts.

Policy implementation demands flawless and well-systematized "coordination" but in disaster management the threshold of coordination is far more intricate and critical than policies in other sectors. Transdisciplinarity is the key to good implementation in disaster management and to obtain this framework, immense preparedness and deep behavioral improvements would not only be required but would also need to be sustained.

Policy implementation in the post-1990s has been analyzed using theoretical tools of new institutional economics such as principal–agent, public choice, and game theory. This has found a larger field of implementation field under the occupation of political expediency instead of logically designed and rationally structured initiatives only to please the vote banks of legislators. Varieties of interests entered policy implementation to deflect and divert policy implementation to produce results quite different than what it was aimed at producing. To insulate policies from various influences and subsequent slippages and failures, a regulatory mechanism with participatory local communities provides an effective answer. Policy science is an ever growing field and it is always the context that defines its implementation. The removal of “time and space” limitations through the digitized basis of technology notwithstanding, even digital modernization gives no insurance against unanticipated outcomes of policy implementation. Pre-emptive planning with paradigms of justice and equity as anchors of implementation would bring the greatest possibility of a success story in disaster management.

Abstract

Government play a very crucial part in responding to disasters. A very pressing concern during the pandemic has been on accountability of governments. Many of the common law countries suffer from the colonial trapping of sovereign immunity, providing legal protection to government actors while working on disasters. In India, we can see that most of the national legislation protects a government actor from judicial scrutiny and failed process rarely sees any repercussion. The European Court of Human Rights, in very few cases, has been able to break away from this limitation under exceptional situations. During the pandemic, some of the legal protection provided was diluted, with courts, civil society, and media demanding accountability when interventions went against the

scientific evidence available. People in authority worked on creating engagement with communities and civil society, but the power remained with the government. The chapter considers some of these examples to identify key actors and creating space for accountability of government within the ambit of disaster risk reduction.

Keywords

Disaster governance · Accountability · Disaster risk reduction

Introduction

With the introduction of the Hyogo Framework and the Sendai Framework for Disaster Risk Reduction (SFDRR), it is clear that disaster governance is not limited to government as it includes civil society, media, academia, and businesses, among others. At the same time, in India, as in most countries globally, the government is still the critical regulatory authority. Often labeled as bureaucratic, inflexible, and wedded to the theory of command-and-control, the work of government at the time of disaster is always under scrutiny as disasters create a period of uncertainty and the ensuing unplanned nature of the response is generally beyond the control of managers (Quarantelli, 1997). Accountability in disaster management has been referred to as accountability by proxy exercised by entities like the media or NGOs (Ploughman, 1997). Establishing standards, codes, and regulatory frameworks has been helpful to establish standardized structures (IFRC, 1994) to hold different stakeholders accountable. However, the voluntary nature of these agreements has rendered their enforcement a big challenge, especially with the government (John Twigg, 1999). Citizens and civil society holding government's accountable is a key part of reducing risk (United Nations, 2008) by the development of plans and monitoring and evaluation, participatory budgeting, and social audit, among others, at the community level (Newbourne, 2008). This requires citizens' engagement in the decision-making process with a clear understanding of legitimate standards on which the action is to be measured (Polack et al., 2010). Three lines of accountability are well recognized – downward government accountability to the citizens, horizontal accountability – within the administrative structure and upward accountability of local institutions to government at the national level (Transparency Accountability Initiative, 2014).

The chapter provides an overview on the functioning of institutional mechanisms for disaster management in India during Covid19 to identify actors and opportunities which can facilitate accountability. The chapter starts with the examination of the principle of sovereign immunity to ascertain the different ways courts have looked at state and individual accountability in disasters and then specifically during the pandemic. The chapter provides an insight of the development of the principle of sovereign immunity during disasters. The chapter concludes by identifying the key actors and factors which could enhance accountability in disaster governance in India.

Can the King Do Some Wrong?

The Restrictive Approach in the USA

The concept of sovereign immunity is best encapsulated in the term – the *king can do no wrong*. Concerns have been raised over the continued application of this common law legacy in a constitutional democracy where government accountability is a crucial feature of good governance (Vicki, 2003). In Dalehite v. USA (346 U.S. 15, 73 S. Ct. 956 (1953)), the Court protected government officials involved in the storage and maintenance of fertilizers in the port which led to massive explosion. Justice Read in his order excluded the government from any liability for errors in the administration as the policy gave room for the independent discretion.(p. 36). The dissent challenged this application as it would keep the government outside the scope of any liability, even for carelessness (Dalehite, pp. 47–60). In Berkovitz v. the USA (486 U.S. 531 (1988)), Justice Marshall created a two-pronged test – whether the action was a matter of choice for the government employee and whether the decision was based on public policy consideration (p 536). The suit would be dismissed if the decision was covered under either of these two conditions. In re Katrina Canal Breaches (Nos. 10–30249, 10–31054 and 11–30808), the lower courts found that the construction of breaches by the Army led to massive flooding during Katrina. The Army was protected under sovereign immunity for the construction of the breaches, but the same was not extended on its failure to maintain the breaches by the lower courts. In appeal the decision was reversed and became a well-known example of a conservative approach of the court focusing more on the financial burden of the liability on the treasury rather than the issue of accountability (Bruno, 2001).

The Rights-Based Approach of ECtHR

The ECtHR recognizes that natural hazards, to a certain extent, are beyond the control of the government. At the same time, it requires that the governments provide institutional mechanisms and guidelines to deal with well-known, predictable levels of disasters of natural hazards (Kolyadenko, 2012 §§ 157). The court also recognizes that an impossible or disproportionate burden cannot be imposed on the state as there is a need for flexibility to accommodate the *operational choices* (Budayeva, 2008 §§ 134–135). The courts have recognized that the state's obligation depends on the extent to which the risk is foreseeable and susceptible to mitigation (K Cedervall Lauta, J Elo Rytte, 2016). The state must assess all potential risks and exercise due diligence to learn about specific hazards like adopting technical precautionary measures (M. Özel and Others v. Turkey, 2017) and establishing contingency plans and emergencies.

A New Shape for Immunity in India

Sovereign immunity was extended to government officials in India only when the negligent person is executing a sovereign function. Many cases, specifically Shyam Sunder v. Rajasthan (AIR1974 SC 890), dismissed the need for such distinctions, which emerged from the Peninsular & Oriental Scheme Navigation Co. case ((1861) 5 Bom. H.C.R. App. I, p. 1). The scope of sovereign protection has reduced considerably. However, there are many provisions like the Disaster Management Act (DM Act) where provisions like the one on good faith read with Article 300 of the Constitution have been used to avoid litigations.

The CAG Report after the Gujarat Earthquake documented instances of purchase of expensive materials with no justification, payment of excessive compensation in some cases, and delays in the payment. The Public Accounts Committee of the Parliament reported a massive diversion of money allocated for the reconstruction to other sectors after the Indian Ocean Tsunami to other purposes (Viswanathan 2009: 45–48). After the floods in Uttarakhand in 2013, a massive bill was charged under the head of flood relief for the stay, travel, and food of bureaucrats working in the flood-affected region in some cases incurred 6 months before the floods in Uttarakhand. These incidents led to internal enquiries by government leading to some penalties which are generally not available in the public domain, thereby preventing any kind of public accountability.

After the Gujarat Earthquake, 2002, in Bipin Chandra Divan & Others v. State of Gujarat ((2001) 2 GLR 1394) the state argued that disaster response was not within the jurisdiction of the High Court as the court cannot take over the work of the Executive. The court dismissed this argument and located its power under Article 21 and the principle of *parens patriae* (para 13–14). The High Court dismissed the request of the petitioners to replace the existing government machinery and asked the government to involve the citizens in the governance process. The state was expected to hold the money sent by people as donations in a trust. The Court pointed out that complete success by all authorities in disasters is not always possible due to the unpredictability of the impact of different *operational choices*.

In the Swaraj Abhiyaan case (Writ Petition (C) NO. 857 of 2015), the Supreme Court was asked to decide on the delay in declaring droughts by different state governments. The court did not consider the negligence and gap in the data collation process as an issue which could prove the petitioner's claim of a deliberate delay. The Court emphasized on the need for a monitoring agency or ombudsman to ensure proper monitoring of policies in the future (para 24). Therefore, the matter focused more on the challenges of insufficient guidelines which lead to flawed operational decisions thereby justifying the limited *operational choices* of different state government.

The rains in Chennai in 2015 were unprecedented, but the primary cause of flooding was construction in low-lying areas, flood-prone areas encroaching the natural reservoirs as pointed out by the Comptroller and Auditor General of India. A range of actors across departments across governments performed unrelated actions leading up to the unplanned urban space by allowing illegal sale of land, changing

flood zones, etc. This creates a challenge in identifying who is to be held responsible, besides the state, when no direct culpability is possible as decisions are properly justified and approved by multiple authorities. The role of courts in such cases is limited, and reliance is to be placed on measures of administrative control focusing more on horizontal accountability rather than downward accountability.

Protection Under DM Act

The DM Act has identified penalties for any offense by a person obstructing or not complying with the government orders under the Act. Concerning penalty for government officers, no proceedings can be constituted for an action in good faith even if the desired objective is not achieved unless a sanction has been taken from the government. Besides the Supreme Court or High Court, no court can adjudicate on the guidelines and orders under the Act. This indicates that PILs and writ petitions are the primary mode of seeking redressal under the Act. For some of these reasons, the DM Act is said to grant a very high degree of immunity to officials (Sarkar & Sarma, 2006). The NDMA and the SDMA prepare annual reports and present them to the central government and the state government, and the respective legislative bodies. The central government has immense power in the appointment determination of salary and power of the NDMA. Any regulation made in this regard or provisions for the DM Act is tabled before each House of the Parliament and allows the Parliament to engage in the rule-making process.

Operational Choices

The principle of sovereign immunity has been watered down considerably as the legal system has developed thereby increasing government's liability. At the same time, courts are conscious of the separation of power between the executive and judiciary and refrain from deciding on policy decisions and defer to the operational choices of officials. The introduction of frameworks, advisory, and guidelines is useful to refine the operational choices for better clarity on responsibility. The Swaraj Abhiyan and Bipin Chandra decision establishes the need for frameworks but refrains from granting compensation or employing qualifying terms like due diligence used by the ECtHR (M. Ozel). The decision-making process and the factors considered for the decision are not questioned indicating the protection given to the *operation choices* of the administration. The space for holding the government accountable remains under the larger umbrella of PILs. In case of disasters, like the Chennai floods, holding individuals – spread across departments, outside and inside government, and across timelines – responsible for the unplanned expansion of the city is impossible. The inability to establish the causal link to hold one liable would expand the application of sovereign immunity in cases of disasters. An examination of operational choices during Covid19 will help further unravel the way India built upon the idea of accountability.

Disaster Management Act: Testing the Water with Covid 19

Basic Structure

The National Executive Committee (NEC) is the principal executive body, responsible for the coordination and monitoring of disaster response under the guidelines of the National Disaster Management Authority (NDMA). Mask mandate and social distancing were introduced by the NDMA and enforced by Committee's orders (MHA 40–3/2020-DM-I(A), 14th April 2020). During Covid19, the NEC headed by the Home Secretary issued directions for all ministries which were modified multiple times based on the learnings and the feedback from district administration (MHA 40–10/2020-DM-I(A), 23rd April 2020). These orders acknowledged the on-ground challenges created due to the multiple interpretations and allowed the district administration to ascertain the meaning based on local requirements (MHA 40–3/2020-DM-I(A), 3rd April 2020) and the requirements of the migrants (MHA No. 40–3/2020-DM-I(A), 29th March 2020). These orders and guidelines indicate a basic feedback mechanism facilitated by the media, local administration, and state governments contributing.

Too Many Cooks?

The NEC constituted an empowered group of officers for comprehensive and integrated response plan on a range of issues (MHA 40–3/2020-DM-I(A), 29th March 2020). The group, among other things, worked on a supply plan for medical oxygen during the second wave (MHA 40–6/2020-DM-I(A), 16th April 2021) and recommended diversion of oxygen during the rapid increase in demand (MHA 40–6/2020-DM-I(A), 18th April 2020). While subsequently, in 2021, on the order of the Supreme Court, the National Task Force was constituted to recommend a scientific, rational, and equitable distribution pattern of medical oxygen and monitor and audit the supply. Multiple bodies like the National Task Force and Empowered Group working on oxygen supply appear to have similar functions with the final deliverable to ensure adequate oxygen supply. Even with significant overlaps in the work of these two bodies concerning oxygen, the condition during the second wave (World Bank, 2022) indicates that both these bodies failed to achieve the mandate given to them. Even if the condition was not as dire, the duplication of task needs attention.

In some cases, the NEC relied on media reports to identify violations of lockdown and guide the corresponding secretaries to improve the enforcement (MHA 40–10/2020-DM-I(A), 21st May 2020). As per the report submitted to the Supreme Court in Alakh Alok Srivastava, the Prime Minister and a group of ministers and secretaries – Health, Aviation, Shipping, External Affairs, and Home – were working on Covid long before the lockdown. Similarly, the enforcement of the lockdown was to be supervised by Inter-Ministerial Central Team (MHA 40–10/2020-DM-I(A), 19th April 2020) guiding the entire police administration across the country. The engagement of multiple bodies with similar functions creates question on accountability, the hierarchy, and the possible overlap of functions which may prevent an

efficient use of limited resources. The courts in multiple proceedings across the country questioned the district administration or the chief secretaries, while the different specialized bodies were outside the scope of questioning. Some of the bodies mentioned above were expected to do that as per the mandate. While the district collector is, and rightly so, to be held accountable, the position and the accountability of the newly constituted bodies remains unclear.

In the second wave, the test track treatment protocol was used to guide the state and district authorities (MHA 40–3/2020-DM-I(A), 23rd March 2021). This was followed by a range of guidelines issued by the Ministry of Health and Family Welfare for home quarantine, isolation, and medical protocols. Concerning the availability of medicines, monitoring the availability was assigned to the National Pharmaceutical Pricing Authority and the Drug Controller General of India. They worked in consultation with manufacturing companies and state governments (MHA 40–6/2020-DM-I(A), 22nd April 2021). The governance systems concerning disasters are inter-connected and inter-dependent, and therefore accountability cannot be restricted only to the district administration or the NEC alone.

District Administration

The District Disaster Management Authority (DDMA) has the district collector as the chairperson and the elected representative of the local authority as a cochairperson. The role of the DDMA is much broader as it works on enforcing the guidelines issued by multiple entities. In one of the first few orders of the NEC, the District Collector (DC) was required to appoint an executive magistrate as the incident commander to enforce the restrictions before the lockdown (Annexure to Order 40–3/2020-D, 24th March 2020 & PIB 3rd April 2020). The DDMA, headed by the DC with officers from Health Department, Police, and Education, among others, acted as the last mile connection between the people and the institutional governance. During the second wave in 2021, the NEC gave more space to the local administration to employ evidence-based decision-making as they provided the basic parameters allowing the local administration to figure out the restrictions based on positivity rate and the availability of oxygen-supported or ICU beds (MHA 40–3/2020-DM-I(A), 26th April 2021).

In terms of accountability, the DCs were expected to be working under the supervision of the Chief Secretary of the State. Regular meetings between the higher authorities of the state and the DCs were reported in many states, and regular communication via the SDMAs was also observed. The nature of interactions are said to be consultative ((MHA 40–10/2020-DM-I(A), 23rd April 2020), but this remains a matter of research and would require a more immersive engagement. The creation of the DDMA is expected to provide the space for the different departments to work together under the supervision of the DC and in a way create a consultative process holding each other accountable and responsive to the changing needs of the time. In many instances, the Courts have summoned DCs and have demanded responses based on PILs or have questioned them on the compliance of its orders. The courts especially High Courts during Covid19 became very active especially

during the second wave to question the DCs, Chief Secretaries, and Health Secretaries on enforcement of guidelines or drawing attention to an overlooked issue. The upward and horizontal accountability remains within the confinement of administrative structures, but the courts have been able to create an additional level of upward accountability. The downward accountability toward the citizens remains discretionary and is not formally institutionalized.

Social Welfare Schemes

During Covid 19, the utility of this social welfare schemes was evident as the government employed welfare policies like National Food Security Plan, Jan Dhan, and MGNREGA, among others, for extending support to vulnerable groups after the lockdown. The employment of these schemes provided a safety net to people whose livelihood and food were affected by the restriction imposed during the lockdown. Therefore, the study on disaster governance cannot be limited to the DM Act alone and needs to encompass the different social welfare schemes which are crucial in reducing risk.

The enforcement of schemes like MGNREGA are riddled with administrative challenges (Salian & Leelavathi, 2014) like delayed payments, no job cards, fake cards, and low payments. It is important to remember that the beneficiary of the schemes are people with limited means and thereby have limited access to the DC or any court as local power stratification plays an important role in accessing these spaces (Masiero & Maiorano, 2018; Agarwal, 2016). The point of contact for many of these schemes is the Gram Panchayat, ward officer, or the ration shop owner. There are mechanisms created like social audit developed to ensure supervision and accountability, but in many cases the nature of supervision varies (Varghese, 2019). Due to better accessibility and more dependency on these schemes, the engagement of the community is much higher but the redressal process is often limited (S. Dutta, 2015). The accountability is limited to surprise inspection by superior officers or official complaint filed by people. The management and settlement of these complaints is often lost in the myriad of administrative processes in the absence of institutionalized grievance redressal (Agarwal, 2016). Quite often during disasters, the point of contact for many of these schemes is unavailable or inaccessible. The Department of Administrative Reforms and Public Grievances required every department and the central government's Ministry to appoint a nodal officer to deal with public grievances for COVID-19 with details (DARPG, 30th March 2020). The status of complaints before these nodal officers is unclear and is definitely not available on the official websites.

Covid 19 and Indian Courts

The Indian Supreme Court, in mid-2020, looked into matters emerging from the enforcement of the lockdown. In some instances, like the case of the juvenile home, the court took cognizance of reports from the media and passed orders on the nature

of protection required in the juvenile homes. The case of Alakh Alok Srivastava v. Union of India (Writ Petition(s)(Civil) No(s)0.468/2020) was very vital as it elaborated upon the different *operational choices* of the central government. In its submission to the court on different issues raised, the central government was able to provide their justification for key decisions. The government highlighted the impact of fake news and misleading information leading to the migrant crisis.

The High Court of Delhi questioned the DGCA on Covid-appropriate behavior in the period between the first and second wave (Court on its own Motion v. DGCA, Writ Petition (Criminal) N. 3184/2021). Based on the facts presented by the petitioner and the media reports, the court acknowledged that Covid-appropriate behavior was not being followed in many cases. The decision employed the media and citizens to refine the instructions of the DGCA for more effective preventive measures. Specialized bodies like the National Commission for the Protection of Child Rights (NCPCCR) put together data on children orphaned due to Covid, which gave good insight into the gaps in the data assimilation process of the States and highlighted the impact of the lockdown on children. The NHRC, in June 2021, released an advisory for the protection of the rights of children where a wide range of issues was mentioned – education, psychosocial care, nutrition, data management, and adoption, among others (NHRC R-17/8/2020-PRP&P, 2nd June 2021).

The Allahabad High Court questioned the need for holding elections at the time of a pandemic in light of the death of 135 Shiksha Mitras on election duty in April 2021 and also ordered to constitute a Pandemic Public Grievance Committee (In-Re Inhuman Condition At Quarantine Centres v. State of U.P. PIL No. 574 of 2020). The Court was not impressed with the limited facilities provided in rural parts of UP (para 6). The court appointed a judge above the rank of Civil Judge senior division to act as a nodal officer for the High Court in crucial districts to monitor the compliance of its orders and verification of every death reported. Orders were delivered by different High Courts across the country during the second wave especially regarding the availability of hospital beds and oxygen for the patients. Some sweeping statements were given by the Allahabad High Court which were set aside by the Supreme Court as they were difficult to enforce and were therefore considered advisory in nature rather than directive. This is a good example of the High Court negotiating the scope of judicial overview on the grim consequences of the operational choices made in the past which was restricted by the Supreme Court considering the challenge in the practical enforcement of the decision, thereby recognizing the limitation of the executive's operational choice.

In one of a kind judgment, the Allahabad High Court proposed to hold the DC responsible for culpable homicide for the deaths in the second wave. This statement of the High Court brings forth the question on liability to the forefront in the case of a disaster. The DCs and Secretaries in question are not the sole entity responsible for failure of hospitals as it is a part of a systematic failure. Since it was just a statement, the legal position on individual liability of government officials in this issue is unclear.

Multiple media sources reported the disparity between the number of official deaths and the number of people cremated or buried in different parts of the country. The international media also picked up the extensive work done by Newspapers in

Gujarat regarding the disparity in numbers. Further, when asked in the Parliament about the number of deaths due to lack of oxygen, no data was found as the states being responsible for health did not collate this data (Biswas, 2021). This is an excellent example of media, public representatives using their offices to question the government, but this also shows the futility of efforts as the matter is set aside on technical grounds.

Conclusion: Unraveling Accountability in Disaster Governance

For disaster risk reduction, effective accountability requires capacities of citizens and civil society to hold governments accountable, supported by an adequate information and communication system between the government and the citizens (United Nations, 2008). The citizen involvement during Covid was observed in some cases at the district level, with a feedback loop created to ensure compliance of the lockdown. Specific provisions concerning engagement with local leaders were also mentioned in the guidelines. However, the space is primarily consultative and does not translate into a formal grievance redressal channel.

Social accountability can be included in a range of actions like monitoring of public budget, participation in the planning process, among others, to hold the state accountable (McNeil & Malena, 2010). A supportive governance structure is essential to enhance and ensure coping capacities in societies and thus reduce their vulnerability. Governance influences how the stakeholders, i.e., the state, the private sector, and civil society organizations, are willing and able to coordinate their actions to manage and reduce disaster-related risk (UNDP, 2010). There are multiple institutions and actors from different areas of specialization involved in reducing disaster risk like – technical, political-administrative. At the same time, the lines of accountability get blurred when the systems cannot cope with the stress created by disasters (Coskun, 2013). Clarity on these stakeholders' roles and responsibilities is crucial with a transparent chain of command. During Covid, initially the restrictions imposed were very stringent and gradually modified to allow the local administration to work more space. The presence of multiple bodies with overlapping functions and challenge in reaching the last mile indicates the need for more clarity in roles not just within the government but with external actors as well. In some cases, the supervision of the district administration on civil society helped ensure that there was a collaborative association rather than an antagonistic relationship.

Owen Main Podger points out that building and sustaining public trust is critical during and after a crisis caused by a disaster. It becomes more critical because often:

1. Institutions themselves are at times devastated by the disaster.
2. Resource providers for relief and recovery are frequently far removed from the crisis.
3. Political interest disappears before recovery is complete.

The second wave could be considered a complete breakdown of critical support systems, rendering the people helpless as the black market for medicine and oxygen soared. A good part of Covid19 was the availability of government notifications, WHO guidelines in the public forum with regular press briefings on relevant ones by the Health Secretary and by competent authorities at the state level. Even the courts, in some cases, directed authorities to make information public on some issues. The availability of information online from different ministries was fruitful to ensure transparency and clarity on basic ground rules, which is often not the case in other examples of disasters.

For the past two decades, decentralization has been an essential feature of governance structures in South Asia. Factors like income disparity, gender divide, and caste-based differences, among others, are factors that directly have an impact on local-level accountability (Haque, 2008). The DM Act is one example of creating a decentralized system with the NDMA and NEM at the center and the SDMA and then the district level and state-level executive authorities. Decentralization is often justified to bring more people within the governance framework and improve accountability as the power is located closer to the people who are affected by it. In his work, Philip Mawhood (1984) has highlighted that decentralization often leaves the institutions at the lowest level of hierarchy with limited power and resources as the decision-making authority stays with the higher authorities. Therefore, in institutions where power is decentralized to actors who are not accountable to their constituents or are accountable only to their superiors or to themselves – the expected benefit of decentralization in the form of efficiency, equity, and development cannot be achieved. This is a major concern with respect to the challenges in the enforcement of social welfare schemes in India which have a clear impact on disaster governance. The gaps in the enforcement and more focus on upward accountability especially of the DC rather than public accountability create this challenge.

The accountability of expert bodies was limited to the government itself, most of them reporting to the NDMA or NEM. Information on different aspects of significant decisions was relatively unknown, and court cases became a good source of getting information in the public domain. Horizontal accountability has been utilized in some capacity within the administrative system in India. After the reported incidents of financial irregularities in the use of flood relief funds in Uttarakhand, an internal enquiry was constituted, which led to some repercussions for the staff. In the Puttingal temple fire incident, the administration was not penalized. However, the internal mechanisms of the officials led to the transfer of the police officer responsible for preventing this incident. The informality and the ad hoc nature of these mechanisms leave much power in people's hand with no accountability and no grievance redressal for the individual.

Several stakeholders like the media, civil society, and courts, among others, played an essential role during the pandemic. The role of the media has been a matter of debate as some media outlets worked on unraveling the gaps – like the number of deceased in Gujarat or the BBC reporting using RTI to ascertain the

details on different government bodies (Biswas BBC, 2021) while in some cases FIRs were filed on some reports (Vinod Dua, 2020). At the same time, the media was also criticized for diverting attention from the medical emergency to tabloid-type news reporting on unrelated issues.

Civil society was a crucial factor in providing support at the time of lockdown and, in many cases, ended up being the only entity reaching the urban poor or filing PILs for vulnerable communities. The more institutionalized organizations like UNDP or UNICEF worked on collating data and releasing reporting on the impact of the restrictions on vulnerable groups like children and migrants. The support of civil society to the district administration was well appreciated in some places. No reference has been made to considering the civil society organization as a monitoring agency. The space for working with NGOs and humanitarian actors is to be explored with more focus on accountability.

The deference to operational choices in the decision of the courts is obvious especially in the early cases of 2020. In the second wave, the numbers and an absolute helpless situation pushed many High Courts to appoint monitoring bodies and threaten to impose severe penalties on individual officers. Some of the High Courts made attempts to unravel the operational choices by engaging with ideas of due diligence, but the same was superseded with the Supreme Court. It is to be seen whether the positions taken by some High Courts during the second wave will find a space under the sun in the future or as the Supreme Court's order indicates we give way to the operational choices of the executive.

The governance structure for disaster governance has not created many formal mechanisms for accountability. Actors like the media, courts, specialized expert bodies, and civil society have created the space to demand some accountability. Formal mechanisms were created due to Covid19 but restricted to a more consultative manner and need to be more formalized.

Abstract

Natural and man-made disasters are a regular part of the human experience on the planet, though in this particular era certain natural disasters (e.g., flooding, wildfires, and excessive heat) seem to be more frequent and intense. An often overlooked issue in disaster management and recovery is the property rights regime that underlies human settlement. Whether land is privately, publicly, commonly, tribally, formally, or informally claimed (or “owned” in some other way) makes a tremendous difference in the ability of individuals, NGOs, and governments to manage disaster recovery.

This contribution examines the current global debate over the right to property in the context of an ever-increasing urban population. In particular, claims for increased Western-style private property as a vehicle for increased social stability and increased wealth are scrutinized in the context of their compatibility with sustainable disaster recovery. Research suggests that it is the institutions that support and legitimate property that appear more important than the actual form of property rights itself. The outcome of this examination suggests policy directions for property’s form and civic and public sector action to achieve a form compatible with disaster recovery.

Property, Private Property · Informal Settlements · Hernando De Soto

Introduction

The twenty-first century began with several notable trends, a few of which are particularly relevant to this contribution. One set had to do with land use.

It appeared to many that we have entered a period of increasing ecological fragility. The popular media and scientific literature are replete with stories and investigations of, for example, melting ice caps in the polar regions, receding glaciers, deforestation, increasing forest fires, desertification, water supply disruption, previously unrecorded heat levels, extended drought, unstable weather systems (see, for example, Fountain, 2022; UNEP, 2022; Yaffa, 2022). A consequence of these changes is the potential for and reality of a broad range of natural disasters, such as rising sea levels, floods, wildfires, earthquakes, tsunamis, volcanoes among others.

Coterminous with ecological fragility is the trend of urbanization. Sometime in the early part of this century human settlement became, for the first time in recorded history, more urban than rural. While this has long been the case in the developed world, we are now a planet of cities and city dwellers. In and of itself this need not be a problem. But the problem is that much of the urbanization that is occurring is in the developing world and is designated as “informal.” Informal settlement means that dwellers from rural and minor urban areas migrate to a major city where they settle without a secure sense of place, on spaces that often do not have adequate (if any) physical or social infrastructure, and which may actually be dangerous (e.g., unstable hillsides). The places are often labeled slums (Davis, 2006; Bansal, 2022).

A second trend is institutional and legal. Of concern here is the renewed focus on property rights (von Benda-Beckmann et al., 2006). Largely spurred on by informal urbanization, and the tenuous situation of most informal settlers, an argument emerged for the necessity to formalize informal settlers and settlements through the formulation and granting of private property rights. This argument was most prominently advanced through the work of Hernando De Soto (2000). De Soto contended that if and when settlers were granted secure private property rights both their sense of social security and their opportunity for economic development and advancement would be improved.

This contribution explores the history and current status of the argument for the granting of private property rights. In so doing it poses the question of whether such an institutional solution is the only or even the best way to address natural (and human-made) disasters, and what place there is for other approaches.

Private Property in Historical Perspective

The disasters that get our attention – the ones that we “care about” – are generally the ones that occur in the context of human settlements. And human settlement means that decisions have been made (historically or consciously, culturally or legally) to

allot uses of land with certain privileges and restrictions. We refer to these privileges and restrictions as property rights. And they confer upon the “owner” (controller) of the rights the ability to do things – to use the land, such as building upon it or putting it into production, to transfer it, through market transactions such as sale or lease, to gift it through, for example, inheritance. Rarely, though, are these rights unlimited. Often, especially in modern times, they are subject to privileges and restrictions put forth by society through government, such as through urban zoning regulations. Throughout history, humans have allocated access to land in a wide variety of ways globally. Land can be tribal, common, customary, aristocratic, state (public), patriarchal, matriarchal, and often a mix of all these at the same time. Often these property systems arose to address different ecological conditions, and always varying historical and cultural circumstances. And all of these property systems “worked,” and all were, at the same time, problematic.

In the late 1600s, English philosopher John Locke began a multi-century discussion arguing for the widespread privatization of land (Locke, 1988[1689]). Private property (on the whole) does certain things quite well – it returns to users the effort of the investment of their labor; it provides owners with a sense of security, investment, and equity; it is an asset against which they can borrow for the purpose of improvement or for other economic activity; it can lead to “pride of ownership,” which with residential property can mean care and upkeep, gardens, etc. Locke’s argument has resonated through the centuries (though his caution that it works well when there is “at least . . . enough [land], and as good, left in common for others” (para. 27 of Second Treatise) seems to be less present in the minds of many). Locke’s ideas had great influence on the founders of the United States and their Declaration of Independence from England in 1776. Locke’s ideas on property also influenced Jean-Jacques Rousseau who in turn influenced the activists in the French revolution of 1789 (Rousseau, 1994[1754]). And Locke’s ideas informed Adam Smith and his treatise for the emergence of market economics, which itself argued for the need for clearly articulated and defensible property rights (Smith, 1937[1776]) (these matters are discussed in more detail in Jacobs (2013)).

From the sixteenth century through the mid-twentieth century European powers colonized Africa, North and South America, Asia, and Southeast Asia. Wherever they went Europeans encountered alternate property systems, which they choose to ignore or obliterate, replacing indigenous property systems with Western property systems that enabled extensive resource harvesting and exploitation (see, for example, Cronon, 1983 for a discussion of the property system conflicts that occurred between European settlers and indigenous peoples in northeastern North America in the early European settlement era).

The end of the Second World War began a multi-decade period of decolonization, as the European powers pulled back from their ownership and control of foreign countries. But this period also gave birth to a new focus on property rights. Under the guise of promoting economic development through efficiency in agriculture, Western advisors urged reform of property systems toward the Western model of private property. The overall argument was that private property would lead to higher yields, which could become production surpluses, which would facilitate exports, which

would bring in foreign capital, which would yield funds for investment in social and physical infrastructure. A compelling story.

In this period, Western countries counseled developing countries in Africa, Latin America, Asia, and South Asia to undertake considerable revision to their traditional property rights regimes, primarily in agriculture, though in all natural resource sectors (forestry, grazing, and mining). Bilateral international aid agencies such as the United States Agency for International Development (USAID), Great Britain's Department for International Development (DfID), Germany's Deutsche Gesellschaft für Technische Zusammenarbeit (GTZ), and multi-lateral international aid agencies such as the United Nations Food and Agriculture Organization (FAO) all largely offered similar counsel (many of these and related international aid agencies have had subsequent name changes). While the activity of the bilaterals and multilaterals continued on through the decades of the twentieth century, the prominence of a global discourse on property rights faded for a period in the latter decades of the twentieth century.

Private Property Advocacy in the Twenty-First Century

The birth of the twenty-first century brought with it a renewed focus on property rights, especially private property rights.

A major reason for this reemergence was the work of Hernando De Soto ([2000](#)) and the impact of his ideas. De Soto shifted the global property rights conversation from rural to urban areas by focusing on informal settlement in the developing world. Like many others, he pondered how to regularize these settlements, as the conditions for residents and their environs were problematic. In essence he asked: “how can the poverty of informal residents and their need for a comprehensive and effective program of economic development be addressed?”

De Soto’s answer was a simple and compelling one. According to him, the poor needed to acquire rights in property, specifically formal title for the land they occupied. If they did, he reasoned, such acquisition would give them spatial security (they wouldn’t worry about displacement), and they would have an asset which could use for investment (in their place of living) and borrowing for other economic activities.

De Soto’s ideas proved wildly popular with (neo)conservative political leaders in the West including the US Presidents George H. W. Bush and Bill Clinton, and French President Emmanuel Macron. For a period in the first decade of the twenty-first century De Soto was a regular invitee to the World Economic Forum (Davos) where he mixed with economic, political, and cultural “influencers” (to use a contemporary term).

However, De Soto’s ideas have also been subject to deep criticism, even hostility, from scholars and activists (for an early example, see Gilbert, [2002](#)). Some activists see him as an apologist for the right, providing justification for actually making the poor poorer. Where informal settlement upgrading has occurred and has involved the granting of formal titles, it is not clear that it has actually benefitted the poor in

the way De Soto suggested it should. Instead it appears that it is often the middle classes who acquire the titles, and the poor are themselves displaced from their settlements into new settlements. Are they any better off? Many say no. Often these new settlements can be less centrally located, and require more complex (and expensive) transport between home and work (for a lauded review of decades of slum upgrading efforts in sub-Saharan Africa see Gulyani & Bassett, 2007).

In addition, some scholars argue that De Soto's investigative methods and his data do not actually "prove" what he says they do. Attempts to independently verify his study results have not yielded the conclusions he offers forth.

But in most ways these critiques are and have been immaterial. De Soto's ideas appealed to powerful individuals in the public and private sectors. And it was this appeal that in a very real way validated his arguments.

What We Know About Property

People have always developed rules whereby they allotted rights to property. These rules took many forms, and were shaped to the ecological and historical circumstances that human communities found themselves within. And just as there have been many forms of property there has been long-standing and on-going conflict over the best form for property.

As the global environmental movement was emerging in the late 1960s, population biologist Garrett Hardin ignited a debate about property with his article *The Tragedy of the Commons* (1968). To some, he seemed to suggest that for efficient and effective natural resource management – and especially those resources which were "commons" (air, oceans, etc.) – it was necessary to extend the institution of private property. As such, he fit into the centuries-long argument by Locke, Rousseau, and Smith, and pre-dated the argument by De Soto.

But the Nobel Prize winning political economist Ostrom was among the most prominent to take up Hardin's argument and to suggest he was wrong, or that he at least oversimplified what was, in reality, a complex situation (Ostrom, 1990; Cole & Ostrom, 2012). She pointed out that "the commons" could be owned in a variety of ways and that many of these ownership modes could be quite successful – for the owners and for the resource. She and others pointed out that property has always been and continues to exist in a myriad of forms; one scholar has denoted its current status as "polyrational" (Davy, 2016).

How does this impact the form of property for disaster recovery? In many ways the research literature is quite clear about several things. Property (often referred to as land tenure) is a crucial component of disaster management and recovery, and yet an often under-considered and undervalued component (Brown & Crawford, 2006; Caron et al., 2014; Mitchell, 2011; Register & Escaleras, 2007 are among many who make this point). A significant reason why property is important is that when there is a lack of property records, those impacted by disasters (most often among the poor and those living informally) suffer disproportionately in the recovery process (see, for example, Kälin, 2005; Kenny et al., 2006; Mitchell, 2011). So in instances of

disasters, especially in developing countries with large informal settlements and a lack of property records, the disaster recovery process can often result in significant displacement among prior residents and subsequent land grabbing.

However, privatization of land a la De Soto's proposal is not necessarily the only or the best solution to this situation. Privatization itself presents significant challenges and problems. Heller's scholarship (1998, 2010, 2013) presents an extended examination of the challenges and problems of *over* privatization of property. Using examples from the former Soviet Union, among others, he shows what can happen when there is pendulum swing toward private rights without enough concern for the community context within which these rights exist. My own experience working on land and property issues in Albania in the 1990s under the auspices of the US Agency for International Development affirmed this observation. I saw firsthand how privatization (after a multi-decade period of forced social ownership) led owners to have concern only for their apartment units but not the hallways or other common areas in a multiunit building, or only for the precise legal definition of the space around their building, which led to neglect and deterioration of yards that were now "a no man's land." Heller's analysis about the dangers of over-privatization of property has been challenged, but this challenge is largely ideological rather than empirical in nature (Epstein, 2011).

Reale and Handmer (2011) are among the many who point out that in the context of disaster management it is not just or even primarily the form of property that ends up mattering. Rather, it is how property is embedded within a set of strong institutions that then allow a property form to function as it is theorized to function. What are these institutions? Reale and Handmer (2011) identify (a) a strong and enforceable legal system, (b) an up-to-date and functional land records system, and (c) a governmental system with legitimacy and authority. Unfortunately, it is precisely these institutions that are often lacking in developing countries. So other forms of property – tribal, common, customary, aristocratic, state (public), patriarchal, matriarchal, etc. – are often no more or only marginally more effective in disaster management and recovery than private property. In this vein, Raschky (2008) found that countries with stronger, more well-developed, and socially respected institutions had fewer victims and lower economic losses from natural disasters.

Conclusion

So what is the best form of property for disaster management and recovery? Property systems can take many forms. All are both functional and dysfunctional; there is no "perfect" solution, only a solution that works in the moment, for a time, and within an ecological, economic, and social context. And as that context changes, it is likely, even desirable, that the form of and for property changes.

What we know about property is that it has always been a socially contestable and malleable entity.

Private property as promoted by De Soto and others is intended to address issues of intense urban poverty and a lack of economic development in informal

settlements. It has that potential. In theory private property could help to deal with a range of issues and problems that arise in disaster recovery when claims to property are muddied – problems such as displacement and land grabbing. But private property can also contribute to and create its own set of problems, such as securing the rights of women and children when the overriding social structure is one that expects property to be held and managed by a male head of household, or excluding whole classes of people based on race, religion, etc.

Private property has a long and admirable theoretical history, dating at least to the work of Locke, Rousseau, and Smith in modern times. It has been promoted in the latter part of the twentieth century through the work of Coase (1960) and others. Yet it is also a form of property that has long been subject to intense scrutiny and debate. Beginning within a century of the American Revolution and Adam Smith's landmark text in 1776, critiques emerged among a range of scholars and activists who were concerned with what and who were privileged by the social and legal institution of private property (see the discussion in Jacobs, 2018, 2022). And these critiques continued to the present day, including an examination of whether a classical and robust set of rights in private property is the best configuration for long-term environmental sustainability (among many exploring this issue see, for example, Stone, 1972; Steinberg, 1995; Freyfogle, 2003; Jacobs, 2022).

Are there alternatives to De Soto's concept of private property? Yes. There are both more social forms of private property (ones that recognizes and incorporates the needs of the community, the future, and the environment, while also being fundamentally private in form), and alternate forms of property (see, for example, the contributions in Geisler & Daneker, 2000). Many of these alternate forms seek to explicitly address the critiques and shortcomings of classical private property.

Alternative forms of property compatible with disaster recovery can be developed and implemented. But several matters precede this step. First – a broader and overall set of purposes for this alternate form of property must be articulated (disaster management being one of several purposes, but only one of several, which property must address). For example Pellissery and Lødemel (2020) use the frame of promoting social citizenship to examine a proper form for property “beyond the [global] north.” So, property’s purpose – security, stability, social cohesion, economic mobility, economic development, democratic citizenship, . . . – needs to clarified. Second – property’s development and implementation is directly tied to the state of supporting institutions: the legal system, the administrative and policy system, and the land records system. Any property system has to fit with these supporting institutions. If it does not, no matter the “elegance” of its design, it will fail.

So there is no one form of property that is correct for disaster management and recovery. But I believe several design components of such a property system are elemental. A property system should promote democratic citizenship: it should promote and legitimate the rights of the individual as an individual and as a member of a community. In particular, a property system should be designed that clearly denotes who has what (a clear and legitimate land records system); it should promote property access across race, tribe, gender, and religion; it should articulate both individual and social rights and responsibilities in property “ownership”; it should

allow for and promote as appropriate public and private initiatives to reconfigure property boundaries (land consolidation), both post disaster and into the future; it should provide for the relatively easy transfer (through sale, lease, inheritance) of property rights; and it must acknowledge the right of the public to manage (regulate) and expropriate (physically take) property for legitimate public purposes. There are of course additional elements; these are offered forth as a building block.

Disaster management and recovery can be facilitated or inhibited by the property system in place. If there is a functional property system for disasters, it is place-specific. There is no “one size fits all” model to offer forth because property systems reflect many things. History, culture, the bioregional ecology, and law are among the factors that have been noted here, and there are others (religion, the economy, etc.).

What is known is that property matters. In the wake of natural disasters decisions have to be made about who can and should have access to land and for what purpose, and under what conditions. Often these decisions involve the public sector. But the way property is held pre-disaster and the strength and legitimacy of the legal, administrative, and land record systems become what is significant for how the public sector can act.

The global challenge – in all countries of the world – is to generate a substantive discussion about the social and legal institution of property. But this is hard to do. What exists today is largely an evolutionary development. At a certain point in time property was designed to fit existing circumstances. Almost without exception those circumstances no longer exist, yet old forms of property has changed incrementally, pushed along by history, culture etc. Absent an emergency, it is almost impossible to get focus on an institution that many (citizens, policy makers) find amorphous. Perhaps the best that can be done is to be prepared to use the (unfortunate) instance of a disaster to come forth with proposals for redesign. Until then, what is important is to work on the legitimacy and functionality of the legal, administrative, and land records systems so that when redesign can occur it has the possibility of succeeding.

Abstract

Disasters are the aftermath of hazardous events. In other words, events triggered by natural phenomena, such as flooding, extreme weather, or technological/structural failure become disasters when they have the potential to cause damage to people, property, essential services, and the environment. This chapter is based on multiple bridge collapse incidents in Argentina, causing extensive damage and disruption in the region and exposing deep-rooted corruption at administrative and government levels. Heavy rains in January 2007 and March 2015 were said to have caused many bridges to collapse within a few days in Tucumán, Argentina, and announcements of funds for rebuilding followed immediately. The press reported the bridges were constructed with funds flowing from a federal

government account whose authorities were convicted of corruption and sentenced to prison. The news media suggested that politicians and local businessmen agreed to a 5% kickback in public works contracts. Worldwide, corruption costs USD2 trillion per year or 20% of all government procurements, with bribery and favoritism being common forms of corruption. We contribute to the discussion on how corruption uses the force of nature to perpetuate itself in a context of weak control mechanisms and low transparency. The case illustrates how government officials use natural hazards turned into disasters to maintain an indefinite state of emergency allowing two negative practices to perpetuate: grant contracts without public tender and contractors cut corners to ensure that the construction needs repairs or reconstructions soon. This combination of factors can result in man-made disasters.

Keywords

Man-made disaster · Riverine flood · Argentina · Corruption · Procurement

Introduction

Excessive rainfall can cause disasters affecting the lives and livelihood of many communities. From time to time, the news report catastrophic infrastructure collapses, and nature is blamed for it most of the time. For example, in the province of Tucumán, a subtropical area of Argentina, there are records of rainfall above the average before the years 2007, 2015, and 2018 when several bridges collapsed. Still, the events of 2015 were attributed to never seen before levels of rainfall, although significant levels of rainfall occurred in previous years (1992, 1997, 2000, and 2001) when none of the bridges in the region collapsed. Furthermore, at a granular level, maximum daily rainfall records in one meteorological station show 279 mm on the worst day of March 2015, which is said to be the cause of many bridges' collapse, but rainfall of 308 mm on one day of December 1997, 225 mm on 21 February 2009, or 206 mm on 27 January 2011 caused no bridge to collapse. This observation led us to question why the rainfall in March 2015 caused so many bridges to collapse or be closed in need of urgent repairs.

Riverine floods, caused by heavy rainfall, are recognized as disasters in the region where many bridges collapsed in 2015. There have been only three riverine floods caused by heavy rains in recorded history, namely, years 2000, 2007, and 2015. Consequently, the research question can be refined as to why the heavy rains of 2015 caused many bridges to collapse, but none in 2000 or very few in 2007. The undamaged bridges were not new, so what could be a possible explanation? Perhaps a fast and unplanned development increased the impervious areas, restricting infiltration of the water into the ground and thus, leading to a quicker and greater magnitude of overland flooding. However, demographic trends show an internal migration toward the main city, San Miguel de Tucumán, while most bridge collapses happened in rural areas that are upstream of the capital city or in a different

basin. The last possible explanation to consider points toward human-caused poor construction quality, rooted in negligence or corruption, leading to label the 2015 bridge collapses as man-made disasters.

Reports suggest the perception of corruption increased for most people in Latin America and the Caribbean in recent years (Pring & Vrush, 2019). Multilateral organizations such as the Inter-American Development Bank, World Bank, International Monetary Fund, United Nations Economic Commission for Latin America and the Caribbean, and Transparency International have produced many documents analyzing and criticizing the corrupt practices of governments in Latin America and the Caribbean. For example, it is reported that 85% of citizens believe that government corruption is a big problem (Transparency International, 2017), and all recipes for improvements are based on this premise.

Regardless of its perception, corruption is pervasive in Latin America and the Caribbean, but little is known about specific groups involved and how corruption practices emerge and persist over time. The World Bank Corruption Spotlight report identifies that anti-corruption strategies must be feasible and aligned with the objectives of actors who are recognized as having significant interests in their specific context or field (Khan, 2017). Despite stating it, the report does not provide a detailed level of analysis, nor of actors, much less of the way in which it is carried out. This approach has helped spread the perception of corruption as a matter for governments alone, paying little attention to how government officials are entangled with the private sector in corrupt practices.

To explain the decisions by involved actors, both in the government and private sector, we use Bourdieu's institutional sociology (Bourdieu, 1977, 1990, 1993; Bourdieu & Wacquant, 2005). From this approach, the relationships of social actors are understood based on their relative positions within the field in power disputes (Emirbayer & Johnson, 2008). The position is determined by the capital that the social actors possess and the value the capital has in that field, which allows us to see the constant struggle to accumulate capital (Everett, 2002) and explain how they do it, in addition to putting in the foreground the tensions and power relations that arise (Emirbayer & Johnson, 2008). Many actors have family ties and use conservation strategies such as nepotism to surreptitiously maintain their status quo, which, in turn, solidify their economic capital.

Following the call of Arellano Gault (2017) for empirical works in Latin America, this study focuses on a specific case in Argentina that, on the surface, appears to be a natural disaster (disaster triggered by a natural phenomenon). The empirical evidence collected points to a plausible alternative explanation rooted in the habitus and its influence on government procurement and its links with corruption. The case is developed with publicly available documents from the national agency of climate/weather, judicial system, and news articles.

The remainder of this chapter is organized into four sections as follows. Section two situates the study in the disasters literature and within the corruption studies with a focus on the syndromes of corruption (Johnston, 2005). The third section presents the case used to illustrate the linkages between disasters and corruption, hinting at the role played by different actors, while the fourth section

offers an analysis of the dynamics between actors and the society using the institutional sociological lens of Bourdieu. The chapter closes with a discussion of lessons learned and concluding remarks.

Intersection of Disasters and Corruption

This study explores the reasons behind a set of bridge failures catalogued initially as the result of natural disasters (heavy rains and flooding). It is vital here to differentiate natural disasters from man-made ones; to better understand man-made disasters, a link with corruption literature mainly focused on procurement studies coming from the accounting literature tradition is introduced.

Natural Versus Man-Made Disasters

In disaster literature, there is a differentiation made between disasters and hazards. The term hazard refers to a severe or extreme event such as a flood, storm, cold spell, heat wave, etc., which occurs naturally anywhere in the world (Centre for Research on the Epidemiology of Disasters [CRED], 2021). Hazards only become disasters when losses are incurred in the form of human lives, properties, and the environment. Generally speaking, hazard and disaster are used interchangeably in lay person's language. To that end, natural disasters are caused by events catalogued as meteorological (weather-related), geophysical (earthquake, tsunami, volcanic eruption), climatological (drought, wildfire), biological (epidemic, insect infection), and extraterrestrial (meteorite strike). In the past decade, between 2000 and 2019, the total human cost of natural disasters was 1.2 million lives lost (CRED, 2020).

Disasters can also be triggered by technological failures, accidents, or the accidental release of toxic materials, all of which are due to various causes, including human error. For example, the recent Beirut harbor explosion on 4 August 2020, shocked the world due to its humanitarian, political, social, and economic impact. In 2010, an explosion ripped through the Deep Water Horizon drilling rig in the Gulf of Mexico, unleashing over three million barrels of oil into the Gulf of Mexico and killing 11 people in the worst oil spill in the United States history (Friedman, 2020). The main reasons for the accident were weakening safety and environmental regulations while pushing to expand oil drilling in nearly all American waters.

Disasters triggered by human-induced factors, such as poor construction, a lack of maintenance, negligence, intentional (terrorism), economic, or political, are perceived as criminal in public opinion. Examples of such events include the Flint, Michigan (New York Times, 2016) water crisis that began in 2014 when the city switched its water supply from Detroit's system to the Flint River as a cost-saving measure in a majority-black town. Soon after the switch, the tap water turned brown, bad tasting, odorful, and caused rashes in the population with concerns of bacteria. High levels of lead (from 11 ppb to 104 ppb within months) were reported causing developmental problems in children. Earthquakes around the world have killed

thousands of people as a result of collapsed buildings because the concrete was diluted, steel bars were excised, or otherwise, substandard building practices were employed. Although it is difficult to evaluate the extent to which corruption might have played a role, the convergence of corrupt contractors, building inspectors, and public officials has been demonstrated in studies (Escaleras et al., 2006; National Geophysical Data Center [NGDC], 2021; Ferranti et al., 2017). The 2001 Bhuj, India quake with a 7.7 Richter Scale that led to 20,005 deaths is one such example.

Corruption in Procurement

The field of government procurement is a major site where corruption flourishes (Berrios, 2006; Neu et al., 2015) due in part to the volume of goods and services the government consumes to the tune of USD9.5 trillion per year (Ferguson, 2019) and in part due to the unique features and participants of this site (Neu et al., 2013). Studies focused on government procurement estimated corruption costs as much as USD2 trillion per year or roughly 20% of all government purchases (Ferguson, 2019). Bribery and favoritism are very common forms of corruption in the process, where government procurement is defined as “*the acquisition by a government department or any government-owned institution of goods or services*” (Ferguson, 2019: 942). It is argued that corruption is facilitated when government officers have a greater opportunity to influence decisions, obtain benefits, and are able to get away with the offence (Schultz & Søreide, 2008). Accounting literature suggests limited transparency and control mechanisms increase the chances of government officials approving purchases to companies linked to friends and family or paying prices that are significantly higher than the market independently from the expectation of receiving kickbacks.

Prior research in the accounting field has highlighted the importance of documentation and form-based practices as control mechanisms, inspection practices, the timing of inspections, and internal audit practices as means of enhancing internal controls to prevent corrupt practices (Neu et al., 2015; Ferguson, 2019). When governments do not understand the magnitude of the corruption, their responses are inappropriate (Upadhyaya et al., 2020), and price differentials can be up to 30% of the contract amount in cases of inefficient procurement, but in cases of corruption, they can be higher (Schultz & Søreide, 2008). The supply side of corruption argues that corporations are constantly under pressure for higher profits, and in the face of high competition, some may resort to illicit means of securing government contracts, highlighting the state–business nexus that perpetuates corrupt practices (Siddiqui & Uddin, 2016). Sikka and Lehman (2015) highlight some of the limits to the effectiveness of internal controls in government procurement programs and how best practices that work in one environment might not work in others due to institutional, social, and economic factors.

The literature recognizes two competing views on corruption mitigation in government procurement; one asserts that proper surveillance systems are universal and applicable across all cultures (Neu et al., 2015), while the other argues controls

by themselves do not affect corruption if they are disassociated from social tensions, legitimacy of the state, and networks of power (Sikka & Lehman, 2015). Adopting the second view, we observe prior research on governance mechanisms has drawn on Johnston (2005) categorization of Influence Market corruption where politicians are often the middlemen (Neu et al., 2013, 2015; Sikka & Lehman, 2015), but there has been very little research done in Elite Cartel environments such as Argentina, where powerful professional networks are said to play a significant role in creating and maintaining corruption practices. Corrupt practices in Influence Markets settings are often characterized by strong state institutions where politicians utilize their connections to collect rents in the form of contributions, both legal and otherwise (Johnston, 2005, 2015; Neu et al., 2013). Corrupt activities in Elite Cartels are often set up to enrich and protect networks and higher-level elites that have the prerogative of changing rules and policies to their favor (Johnston, 2005).

The Case of Tucumán's Failed Bridges

The Province of Tucumán is one of the 23 provinces of Argentina with 1.4 million inhabitants and a population density of 64 inhabitants per square km. Its landscapes are characterized by plains, valleys, and mountains, with part of the Andes mountain range to the west complemented by jungles and arid lands to the east. It has diverse microclimates with averages of maximum temperatures of 25 °C and minimums of 13 °C (Gobierno de Tucumán, 2021). The Salí River is the main drainage basin of the province flowing in a north-to-southeast direction with 12 main tributaries and two artificial lakes – C.Gelsi and Río Hondo dams (Tracanna et al., 2014). Figure 1 shows the hydric map of the province in relation to South America and Argentina, locations of some of the failed bridges, and meteorological stations that measure rainfall data. The rainy season runs between October and March; the heavy rains and the collapse of bridges investigated in this study occurred during the southern summer months. Figure 2 shows annual precipitation in millimeters in six meteorological stations in above-average years between 1990 and 2020, with three of them causing floods of significant proportions as recognized in the international database of disasters (CRED, 2021). Table 1 summarizes extreme episodes listing the top 20 days experiencing more than 150 mm of rain, one of them in March 2015 is when most bridges collapsed.

Collapsed Bridges As a Result of Forces of Nature Aided by Suspected Corruption

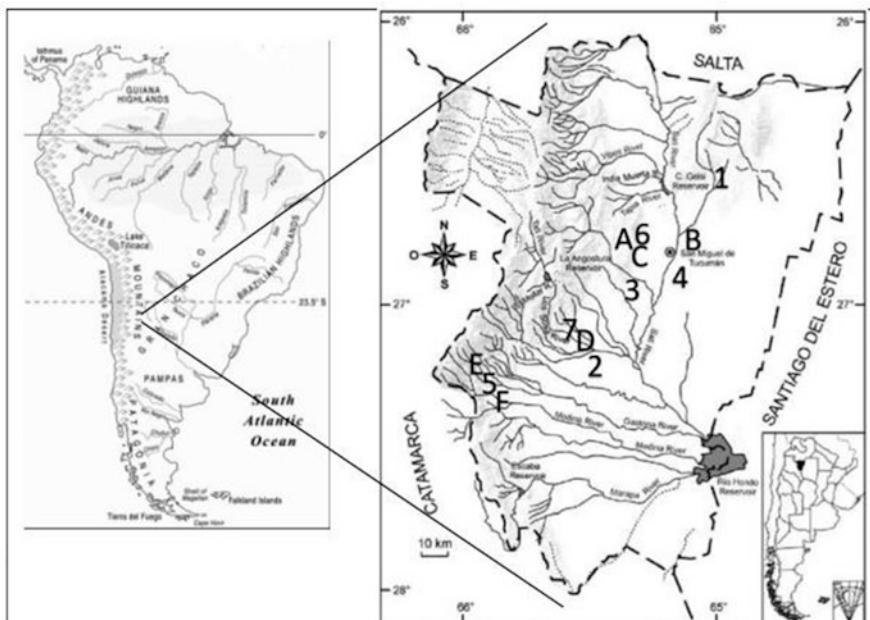

In January 2007, rains exceeded the normal rainfall, causing floods, evacuation of citizens, road damage, and the intervention of provincial and national authorities that declared a state of emergency. As reported in the media, in 3 h, a total of 150 mm rainfall occurred on Wednesday, 10 January, while the monthly average was 196 mm (Pagina 12, 2007) and 11 January had three record measures of rainfall (see Table 1).

Although Greenpeace linked floods to climate change and deforestation practices in native forests (Lipcovich, 2007), historical data suggest 2007 is a record season (see Fig. 2). The consequences included two deaths, over 30,000 affected, and severe damage to infrastructure costing USD192 million (Lipcovich, 2007; Ámbito Financiero, 2007). Among the destroyed infrastructure were National Route 38, Provincial Route 301, and some road bridges.

The Governor of Tucumán, who took office in 2003 and left in 2015, declared in 2007 the state of emergency in the territory by provincial law 7875, and requested help from the National government, whose officials also took office in 2003 and left in 2015 (Pagina 12, 2007; La Gaceta, 2007; Boletín Oficial, 2007a). In a state of emergency, decisions are fast and do not follow prescribed policies, consequently transparency decreases creating a fertile ground for fraud and corruption (Schultz & Søreide, 2008). In the post-disaster phase, complaints of humanitarian assistance being manipulated (Ámbito Financiero, 2007) were quickly dismissed by federal authorities, blaming citizens who “*in these crisis situations [...] bring out their miseries to take advantage*” (El Territorio, 2007; own translation). A recovery plan based on the assessment of the damage was promised by the Governor after a few days of the event. Over 10,000 homes were estimated to be renovated or rebuilt with a plan to prevent Tucumán from flooding, including the systematization of rivers through the Province-Federal government agreement approved by provincial law 7945 (Ámbito Financiero, 2007; Boletín Oficial, 2007b).

In the 2015 rainfall event, many more bridges were damaged, with many located in the northern basin even though the event was not in the top rainfall days for that basin. On the other hand, the southern basin saw record rainfall in March 2015, the second-highest in the province since 1990, recorded by one meteorological station (see Table 1). The 2015 new round of flooding disconnected thousands of people due to damaged bridges (López, 2015; Clarín, 2015; Contexto Tucumano, 2019), several of which had been repaired with federal government funds after the 2007 flood, such as the bridge on Route 301 over Lules river (Costa & López, 2018). The official report for that bridge (see Fig. 1, bridge 3 Lules River), indicated “*The structure collapsed in the early morning of March 11 due to a large amount of water and sedimentary material that collided with the abutments, causing the embankment that connects the bridge to the surface to give way*” (Gobierno de Tucumán, 2016; own translation).

The governments signed a new agreement to repair the damages for a total cost of USD31 million (Costa & López, 2018). A year later, the authorities announced that the repairs were carried out on some of the bridges, while plans for reconstructions were finalized for an estimated amount of USD6.8 million (Gobierno de Tucumán, 2016). Table 2 offers our synopsis of collapsed bridges until 2018 based on publicly available documentation. Comparing the panels of Table 2 suggests that less than half of failed bridges as reported in the press were transparently reported by the provincial government providing accountability for only USD6.8 million or 22% of total funds. These results confirm that a state of emergency reduces transparency and accountability (Schultz & Søreide, 2008).

Map Legend:

Bridge	Bridge Description	Location of Meteorological Stations
1	Salas river, route 305	A #456 Lules, El Nogalito
2	Mandolo and Los Sosa rivers, route 324	B Station Airport Tucumán

7	Zerda river, route 324	

Fig. 1 Hydric map of the study area in Argentina, showing the City of San Miguel de Tucumán, some of the collapsed bridges considered in the study (1–7), and meteorological stations (A–F) in Tucumán province. (Sources: Adapted from Tracanna et al. (2014), lagaceta.com.ar, <https://snih.hidricosargentina.gob.ar/> and <https://ipinimg.com/>)

September 2018 saw the last bridge collapsing amid confirmation of corruption involving federal and provincial officers. The fallen bridge was built in 2015 by a local company using federal funds. Unlike the other bridges, the latest collapse occurred due to structural problems while a cargo truck was passing through it (Costa & López, 2018). The construction company blamed the truck driver and also claimed vandalism during construction. For their part, the provincial authorities related the causes to construction defects (Costa & López, 2018; Merodio, 2018). With a new federal government in power since December 2015, the previous federal government officials were held accountable, and eight officials, including the

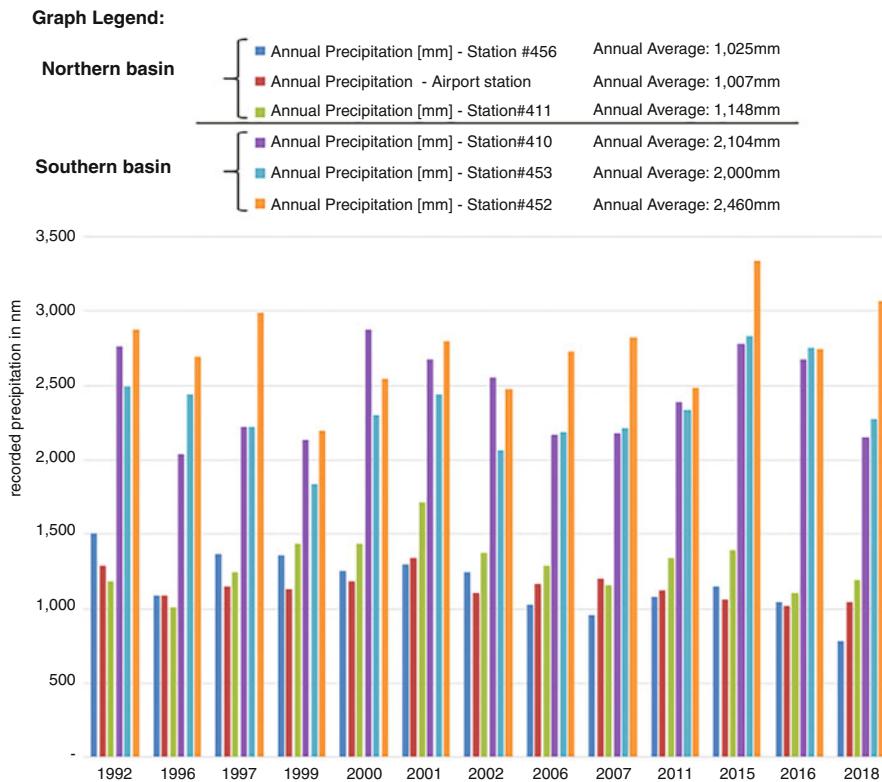

Fig. 2 Years with above-average annual precipitation (in mm) recorded at six meteorological stations from 1990 to 2020. (Source: Prepared with data available at <https://snih.hidricosargentina.gob.ar/>)

national minister of public works, were arrested for bribery and corruption related to other causes, none of them from Tucumán (Costa & López, 2018; Perfil, 2018; Los Primeros, 2018). One of the top officers arrested was the secretary of public works, caught in the act by the police throwing bags of money (USD9 million, expensive watches, and guns) in a nunnery in 2016 (Infobae, 2021b). This secretary had maintained contact with Tucumán provincial authorities during the rainy season of 2007 and 2015, as reflected in multiple news videos and pictures (Contexto Tucumano, 2019); he was responsible for managing the federal funds transferred by the national state to the province of Tucumán for the construction of bridges between the years 2005 and 2015 (Boletín Oficial, 2007b; Costa & López, 2018). Although he cooperated with the justice and exposed collaborators, he was convicted in 2019 by a federal court and released in 2021 on a bond of USD140,000 after his political party returned to power in December 2019 (Infobae, 2021a; Costa & López, 2018; Ámbito Financiero, 2021; Perfil, 2021).

Corrupt Practices in the Procurement of Bridge Repairs and Construction

Investigative journalism uncovers the normal practice of bribing to be invited to bid on infrastructure projects. The mechanism works only with direct purchases where businesses bid for one project, and it does not work well with public tenders where several businesses bid for the same project, as explained by the president of the association of SMEs construction companies of Argentina (Montero, 2018). Public tendering is mandatory for all public works projects unless an emergency is declared or it has to be executed immediately; in this context, the heavy rainfall of 2007 and 2015 provided the appropriate context for direct purchases of all construction or repair works in bridges. According to La Gaceta journalist, the emergency situation declared in 2007 was indefinite because further provincial laws extended it until the end of the year 2021 (Boletín Oficial, 2014), allowing the Governor to “use public resources without cumbersome bidding processes or price comparisons or anything” (Sanchez, 2015; own translation). This is compounded by the lack of transparency of budget execution as shown in Table 2 and predicted in the literature on emergency and disasters procurement (Schultz & Søreide, 2008).

Table 2 Bridges with reported failures in Tucumán

Panel A – Officially reported by the Ministry of Economics, Province of Tucumán as of 2016

Nº	Bridge	Date of failure(s)	Cause of failure	Type of work done	Description
1 ^a	Salas river, route 305	Jan.2007 and Mar. 2015	Natural, heavy rains, floods, river floods	Repaired in 2007. Rebuilt in 2015	In 2015 estimated 12 months work with an investment of more than USD2.4 million
2 ^a	Mandolo river, route 324	Jan.2007 and Mar. 2015	Natural, heavy rains, floods, river floods	Repaired in 2007 and 2015	In 2015 construction done in 6 months at the cost of USD527 thousand by Alfa Empresa Constructora SRL
3 ^a	Lules river, route 301	Jan.2007 and Mar. 2015	Natural, heavy rains, floods, river floods	Repaired in 2007. Rebuilt in 2015	In 2015 construction done in 5 months at the cost of more than USD1 million by Empresa Constructora Argentina de Servicios (ECAS)
4 ^a	La Calera river, route 321	March 2015	Natural, heavy rains, floods, river floods	Repaired	Move of the earth in the embankment by the provincial division of roads (DPV)
5 ^a	Jaya river, route 330	March 2015	Natural, heavy rains, floods, river floods	No data	Access to National Park Los Alisos
6 ^a	Bridge 1, San Javier river, route 340	March 2015	Natural, heavy rains, floods, river floods	Rebuilt from scratch	Estimated 4 months work with an investment of USD791 thousands
7 ^a	Bridge 2, San Javier river, route 340 (Nº6 in Fig. 1)	March 2015	Natural, heavy rains, floods, river floods	Rebuilt from scratch	Estimated 6 months of work with an investment of over USD950 thousands
8 ^a	Zerda river, route 324 (Nº7 in Fig. 1)	Jan.2007 and Mar. 2015	Natural, heavy rains, floods, river floods	Repaired in 2007 and 2015	In 2015 construction done in 6 months at the cost of more than USD633 thousands by Mark Construcción SRL
9	Stream Totori-Illas, route 307	Jan.2007 and Mar. 2015	Natural, heavy rains, floods, river floods	Repaired in 2007 and 2015	In 2015 construction done in 4 months at the cost of USD126 thousands by Inca SRL
10	Los Sosa river, route 324	Jan.2007 and Mar. 2015	Natural, heavy rains, floods, river floods	Repaired in 2007 and 2015	In 2015 construction done in 6 months, cost USD369 thousands by Hugo Cerviño Construcciones
11	Acequiones river, route 309	March 2015	Natural, heavy rains, floods, river floods	No data	No data
12	Seco river, route 324	March 2016	Natural, heavy rains, floods, river floods	Preparing the project	No data

^aBridge reported in Fig. 1

Table 2 (continued)

Panel B – Reported in news outlets on top of those reported by the Government of Tucumán

Nº	Bridge	Date of failure	Cause of failure and source(s)
13	Caspichango River Bridge, route 324	March 2015	Natural, heavy rains, floods, river floods reported in a local newspaper (La Gaceta, 2015, 2018a)
14	Railroad Bridge on Lules River	March 2015	Natural, heavy rains, floods, river floods reported in newspapers (Ámbito Financiero, 2015; La Gaceta, 2015)
15	Zerda River, route 307	March 2015	Natural, heavy rains, floods, river floods reported in a local newspaper (La Gaceta, 2015, 2018a)
16	San Ignacio, route 334	April/May 2015	Natural, heavy rains, floods, river floods reported in a national newspaper (Costa and Lopez 2018)
17	Tapia River, Route 9	Between 2015 and 2018	Natural, heavy rains, floods, river floods damage detected by the government at sometime between 2015 and 2018 (La Gaceta, 2018a)
18	Los Sosa River, route 307	Between 2015 and 2018	Natural, heavy rains, floods, river floods damage detected by the government at sometime between 2015 and 2018 (La Gaceta, 2018a)
19	Bridge over route 312, Los Gutierrez and route 305	Between 2015 and 2018	Natural, heavy rains, floods, river floods damage detected by the government at sometime between 2015 and 2018 (La Gaceta, 2018a)
20	Acheral Access Bridge, route 307	Between 2015 and 2018	Natural, heavy rains, floods, river floods damage detected by the government at sometime between 2015 and 2018 (La Gaceta, 2018a)
21	Muerto River, route 338	Between 2015 and 2018	Natural, heavy rains, floods, river floods damage detected by the government at sometime between 2015 and 2018 (La Gaceta, 2018a)
22	Sali River, route 323	Between 2015 and 2018	Natural, heavy rains, floods, river floods damage detected by the government at sometime between 2015 and 2018 (La Gaceta, 2018a)
23	Stream Barriente, national route 38	Between 2015 and 2018	Natural, heavy rains, floods, river floods damage detected by the government at sometime between 2015 and 2018 (La Gaceta, 2018a)
24	Stream Matazambi, national route 38	Between 2015 and 2018	Natural, heavy rains, floods, river floods damage detected by the government at sometime between 2015 and 2018 (La Gaceta, 2018a)
25	Constitucion Av., Tafí Viejo	Jan/Feb 2018	Delays in the release of funds by National authorities to channel the water stream and build a new bridge (Infobae, 2018)
26	Chico River, route 38	March 2015 and May 2018	Natural, heavy rains, floods, river floods reported in a local newspaper (La Gaceta, 2015, 2018a). Road cut off due to serious flaws detected on the bridge (Café Prensa, 2018)
27	Colón Av. and Lidoro Quinteros diag.	September 2018	Tensioners gave way. The construction company argued the bridge collapsed because of bad maneuvering of the truck, “skidding,” or that the bridge was vandalized before and after its inauguration (El Ciudadano, 2018)

Bribes range between 5% and 13% for bidding in public projects financed by the federal government, and they included Tucumán bridges (Contexto Tucumán, 2018; Balinotti & Sbrocco, 2011). In the lower end of the bribing requirements were housing project bidders who are asked to pay provincial officials known as “*ratita*” (“little rat” in Spanish) a bribe in the range of 5–6%, a portion of which would be contributed to federal officials by companies (Costa & López, 2018). On the higher end of bribes were infrastructure works with kickbacks ranging between 12% and 13% for provincial officials and another 5% for federal officers (Costa & López, 2018). Friendly companies contributed the required percentages to provincial and federal officials, all construction companies were based in Tucumán, and all officers had strong personal and family ties in the province.

The established practices to secure a share in the construction projects funded by federal money date back to 2003 when a new federal government took office and appointed a native of Tucumán as secretary of public works. The bribing practice has been in place since 2004, wherein an officer working for the secretary of public works traveled to meet businessmen to collect kickbacks on federal government-funded projects (Costa and Lopez, 2018). This official was convicted along with the secretary of public works native from Tucumán and mentioned in court rulings as his figurehead (El Marplatense, 2019). In legal proceedings, the former economy minister of Argentina, who resigned in 2005, declared that already in those years, informally, the World Bank had warned about the cartelization of public works that forced the state to pay surcharges (Santoro, 2021). Although federal officials were arrested and sentenced to prison, there were no corruption cases in the Tucumán provincial justice system related to the issue; out of the 219 complaints of corruption received between 2005 and 2017 in the province, only one was successful in getting a conviction (Benito, 2015). One plausible explanation for such discrepancies in practices and results of the federal and provincial justice system can be related to governing authorities, and while at the federal level they changed in 2015, in the province of Tucumán, the same political coalition remained in power.

The mechanism to negotiate and collect kickbacks for federal officers who were based in the City of Buenos Aires was built around individuals with extensive connections in the province of Tucumán. Exploring personal ties helps to understand the nexus between provincial and federal officials that created and shaped a powerful elite suspected of siphoning funds from public works to support their political and business activities. These relations among diverse types of capital and family ties emerge among the actors linked in the collapsed bridges of Tucumán, as reported in the press (Café Prensa, 2018; Contexto Tucumano, 2018; Los Primeros, 2018; Perfil, 2018). The secretary of public works at the federal level between 2003 and 2015, the same who was convicted in 2019, is from Tucumán. He had political aspirations to become governor in 2015 but settled for a seat in the Mercosur Parliament representing the province of Tucumán. His candidacy was endorsed by many unions (Primera Fuente, 2014) and also by a national senator who was the third in the line of presidential succession of Argentina. This national senator was also the spouse of the then Governor of Tucumán (Contexto Tucumano, 2021) and the fourth wealthiest

Senator in Argentina. Her share in the family businesses predates her political career (Perfil, 2011). Many members of the family of the Governor and his spouse hold positions that might contribute to the lack of transparency and control as shown in Fig. 3.

It is argued that the scheme of bribes, kickbacks, and overpricing was complemented by lax controls and low quality in the construction. According to news articles, the “*ratita*” pressured inspectors to expedite certificates for works that had not yet been completed (Contexto Tucumano, 2018). The alleged mechanism might explain why the opposition party denounced to the provincial justice cases of low construction quality and high costs, particularly in housing (López, 2018). To explore if the argument of poor quality is valid for bridges, an interview reported in the press with a bridge specialist, engineer Tomas del Carril, is considered (Montero, 2018). It was first explained that there are many reasons for a bridge to fail in Argentina, with the main trigger being the “hydraulic action” of floods and rain surges; however, the reasons for such failures are normally rooted in design errors, construction defects, or lack of maintenance (Montero, 2018). Specifically, regarding the last fallen bridge in 2018, he commented that the type of structure used for the bridge was more complex and expensive than needed because the “braced arch” type design executed is used for places where there are no support points, such as mountains, a good example of which is a recently built bridge in the province of Córdoba (La Gaceta, 2018b; Montero, 2018).

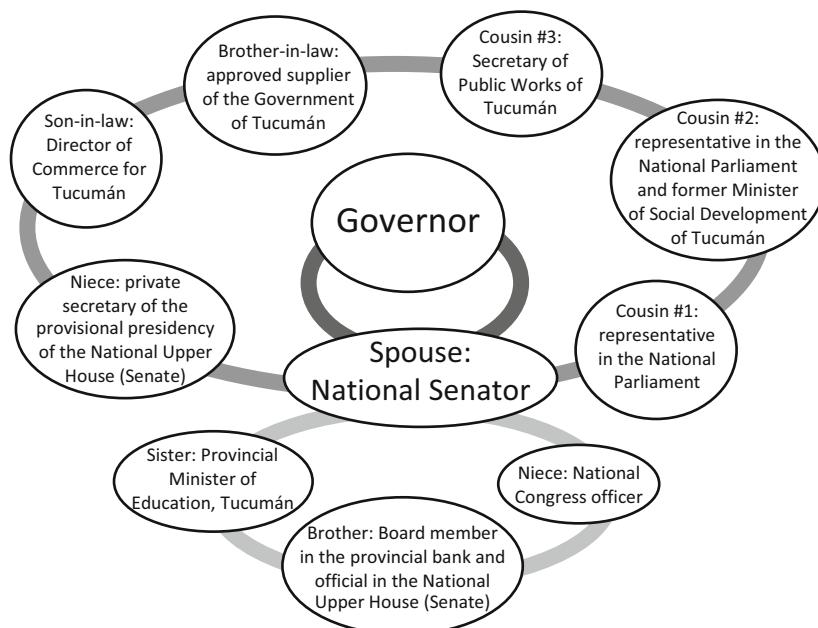

Fig. 3 Network of the Governor’s relatives placed in provincial and national positions of power. (Source: adapted from La Nacion (2012))

Power Pursuit and Building of Economic Capital

Bridge collapses were deemed as disasters resulting from natural hazards, but data reveals a different picture, one that points to deep-rooted corruption at all levels of government aided by natural hazards (Ferguson, 2019). The data suggests bridge repairs and constructions were intended to collapse with above-average rainfall to trigger sequential rounds of financing for reconstruction bypassing public tendering rules. The case recognizes three actors, including officials from the national and provincial governments and construction companies. Each actor participates in the distribution structure of species of power (or capital), whose endowment orders access to specific advantages that are at stake and the possession of one or more types of capital (cultural, economic, social, symbolic, etc.) allows the holders to exercise power or influence (Bourdieu & Wacquant, 2005). Actors are guided by the pursuit of increasing economical capital. Cultural and social capital is a starting point for well-connected families of politicians and business people; for these actors, direct purchases in infrastructure projects present themselves as the best opportunity to siphon wealth from government accounts into their economic capital.

All forms of capital translate into power over other people. Economic capital is recognized as a means to exercise power over resources (appropriation of goods and services) without the need to hide this domination in order for it to be legitimate; it is clearly objectified and with well-defined rights as a means of appropriation. Cultural capital differs from economic capital in both the forms it assumes and in its mode of operation, it can be acquired in the early family environment, and is the one that gives the actor an advantage when it comes to acquiring a position in the field. Although one type of capital facilitates the acquisition of other forms of capital, the accumulation of cultural capital supposes a work of inculcation and assimilation that differentiates it from economic capital and requires a cost of time that must be personally invested by each actor (Bourdieu, 2012).

One mechanism that perpetuates increases in cultural and economic capital is nepotism. Relations among diverse types of capital and family ties emerge among the actors linked in the collapsed bridges of Tucumán, as reported in the press (Café Prensa, 2018; Contexto Tucumano, 2018; Los Primeros, 2018; Perfil, 2018). The secretary of public works at the federal level between 2003 and 2015 is from Tucumán; his political aspirations were endorsed by many unions (Primera Fuente, 2014) and also by the then Governor of Tucumán's spouse (Contexto Tucumano, 2021), who was the fourth wealthiest Senator in Argentina thanks to her share in the family businesses (Perfil, 2011). In 2021 bail was posted for the former secretary of public works by three outside actors based in different provinces (Contexto Tucumano, 2021), although they were all tied to politicians, business people, union leaders, and public officers that were benefited from his disbursements of public funds. Despite being caught in the act of moving money, he claimed to have no money to pay his bail (economic capital), prompting others to help him (cultural capital).

Floods in 2007 saw funds flowing to the province for repair and reconstruction, where an oiled kickback scheme was implemented. To maintain the funds inflow

from infrastructure projects, some actors might have concluded it was less effort to rebuild than propose new projects. The cycle repeated with the heavy rains in 2015 when several bridges collapsed in three days and came the announcement of new funds to rebuild. The coordination of collective action is enacted without the need for explicit structures, systems, rules, and procedures. In other words, the habitus becomes an "*internalized tendency, propensity or inclination*" (Bourdieu, 1977: 214), allowing the actors to act spontaneously in the face of changing circumstances. Social actors use the acquired habitus to express themselves when faced with something new, and in this way, their daily practices help to regenerate and modify certain social orders that have been acquired and whose organizing is emerging.

Heavy rainfall is a constant natural hazard in the province of Tucumán, but human action (or inaction) converts the hazard into a disaster. Researchers affiliated with the Argentinean National Scientific and Technical Research Council (in Spanish: Consejo Nacional de Investigaciones Científicas y Técnicas, CONICET) proposed long-term solutions that involve cultural, ecological, urban, and architectural aspects (Bringas, 2020). Despite political promises after the floods of 2007 that saw the use of federal funds to put together a master plan to prevent flooding, not much was done until 2015 (Ámbito Financiero, 2007). A master plan requires investments in open-air drainage through channels in main cities, underground drainage, garbage management in cities, regulation of building permits for new neighborhoods, reforestation of mountain slopes, and planting trees in cities and towns, among others; however, no systematic action was initiated by the provincial government (Bringas, 2020). If professional networks (families) are invested in protecting sources of economic capital using their cultural and social capital, it is expected they will adopt policies that benefit from the occurrence of natural hazards regardless of the known risk they will turn into disasters. Professional networks in Tucumán can change rules and policies in their favor (Johnston, 2005) to reduce transparency and accountability by declaring the state of emergency.

Corruption practices in themselves are not sustained from a solid entity conception but rather as a process that involves the gradual strengthening of interactions, power relations, norms, and practices that have historically proven to be effective in facing situations that reach those who act in it. The *habitus* makes the relations between actors what it is, and its modus operandi defines how things are done in it (Nayak et al., 2020). This becomes the product of a complex history of accumulated practices that comprise a refined empirical sensitivity toward what is happening and a set of predispositions and tendencies associated with it. In this sense, the presence of past experiences is actively incorporated into decisions that seem eminently sensible or reasonable for a particular group, without the need to resort to explicit rules, routines, or norms (Bourdieu, 1990). Consequently, when complaints of favoritism in humanitarian assistance emerged (Ámbito Financiero, 2007), government officers who quickly dismissed them blaming citizens for being opportunistic and exposing their miseries (El Territorio, 2007) were the truly opportunistic actors. Therefore, what unifies a professional network involved in corrupt practices such as bribery and favoritism is that habitus that is exclusive to it; that way of dealing with things that are idiosyncratic and preparing the actors for the future (Dreyfus, 2014).

Once the social practices settle and incorporate into their habitus, it simultaneously enables and restricts the response action toward the next situations.

Conclusion

Heavy rainfall is a natural hazard that becomes a disaster when corruption enters into the equation of government procurement for critical infrastructures. Corruption takes many forms, and it uses natural hazards to perpetuate itself. The mechanism described of bribes and kickbacks only works if the government procurement system does not use transparent and controlled systems within public tendering. Natural hazards and the disasters they cause force governments to act rapidly to protect the people, but public tendering is slow; consequently, after a disaster, government officials make extensive use of direct purchases, which are less transparent and more prone to irregularities (Schultz & Søreide, 2008).

Powerful elites that control the executive and legislative branches of government, as well as businesses, can perpetuate the cycle of rain-destruction-[new]funds-rebuild where they extract bribes in each round. An important enabler is the nepotism elites exercise, where extended families act as a cartel (Johnston, 2005). “*Those who dominate a field are those who are in a position to make it work for their convenience, which does not imply that they should stop facing resistance, pretensions, ‘political’ or other discrepancies, of the dominated*” (Bourdieu & Wacquant, 2005: 156). Corruption can be curtailed by the judiciary system, backed by an engaged civil society and free press. Despite numerous man-made disasters and legal actions regarding suspected corruption, some dating back to 2008, only a few federal officers (none at the provincial level) were prosecuted and found guilty; at the moment of writing this chapter, only the former minister of public works remains in jail.

The bridge failures in Tucumán suggest that Argentina is a reforming democratic society where political competition is either emerging or going through a significant change where nepotism plays a central role. When unstable political conditions are combined with relatively prosperous economies, many opportunities for corrupt practices transpire (Johnston, 2005). Institutional frameworks in Argentina seem to be moderately strong, but due to intense political competition, contracts are difficult to enforce, and property rights are harder to protect, as shown by the judiciary system’s stiffness and sluggishness. Argentina, like other emerging economies, has strong anti-corruption barriers and internal controls; however, corrupt activities are often set up to enrich and protect networks and higher-level elites (families) that have the prerogative of changing rules and policies to their advantage (Johnston, 2005).

To conclude, we have attempted to advance the knowledge of how corruption uses the force of nature to perpetuate itself in a context of weak control mechanisms and low transparency. The case of bridges’ collapse following specific rainfall events, illustrates how government officials abuse their power to grant contracts and how contractors cut corners to ensure the construction will have to be reconstructed after a short while. The concept of *habitus* (Bourdieu & Wacquant, 2005) allows us to understand corruption as an accepted social practice that naturally

emerges in instances of low transparency and high nepotism. This combination of factors results in man-made disasters.

Abstract

The experience and knowledge of older generation on disaster are rich with local warning indicators from birds, animals, and other natural phenomena. Stories about natural disasters in the past are found in oral literatures, songs, poems, and even lullabies. Such past knowledge can not only reduce disaster risk but also prevent human casualties in the face of disasters. However, indigenous knowledge is often discarded as “unscientific.” Such local knowledge needs to be integrated with the scientific early warning system and could help in disaster risk reduction and increase the resilience of vulnerable communities.

Keywords

Indigenous Knowledge · Traditional Knowledge · Early Warning Systems · Disaster Risk Reduction

Introduction

Indigenous or traditional knowledge has increasingly gained attention among policy makers, development practitioners, academic, and other scientific communities in recent decades. Today, as Mistry (2009: 371) pointed out, the “discourses on development and environment extol the benefits of incorporating indigenous knowledge into policy development, as well as on the ground interventions.” This development is largely seen as the outcome of the inadequacy, and some even consider as a failure, of the modern technologies, institutions, and western knowledge to solve problems so prevalent in remote areas in Asia and Africa. It has come a long way from being considered as an “obstacle to development” to the phase of romanticization and, in the last decade, as an important component in disaster management (Agrawal, 1995; Troglić & van den Homberg, 2018). In the field of disaster research, the potential of indigenous knowledge for effective disaster risk reduction is fully acknowledged now.

However, indigenous knowledge was earlier considered to be unscientific and looked-down for decades by the vast majority of people. They were largely regarded as superstitious belief of socially backward societies. It was seen “as inefficient” and “inferior” (Agrawal, 1995: 413). (For instance, during colonial rule the British considered small settlements of indigenous people with certain agricultural practices such as shifting cultivation as environmentally destructive, and attempts were made to impose a settled agriculture. For more details see Haokip (2020).) Particularly when such traditional or local knowledge help indigenous peoples in maintaining their autonomy from state control, they are decried as unscientific and superstitious and such practices were outrightly rejected. Indigenous knowledge is defined by Mercer and others (2010: 218) as “a body of knowledge existing within or acquired by local people over a period of time through accumulation of experiences, society-nature relationships, community practices and institutions, and by passing it down through generations.” Hence, such knowledge are understood and applied easily by the next generation and subsequently passed on to the succeeding generations through folk stories and songs, dances, paintings, and carvings. However, as it is duly stressed in permanent forum on indigenous issues, “global histories of colonialism, exploitation and dispossession continue to undermine and undervalue these aspects” (“Indigenous People’s Traditional Knowledge Must Be Preserved, Valued Globally, Speakers Stress as Permanent Forum Opens Annual Session,” UN Permanent Forum On Indigenous Issues, 22 APRIL 2019, accessed on 23 February 2022 at: <https://www.un.org/press/en/2019/hr5431.doc.htm>).

There is a realization that indigenous knowledge can make important contribution “to contemporary natural resource management issues, researchers and development workers have been documenting and recording indigenous knowledge with the aim to produce a bank of knowledge which could be incorporated into development projects” (Mistry, 2009: 373). In recent decades indigenous knowledge on the environment and ecology as a whole are found to be sustainable and thus ignited interest in such knowledge system. The potential for effective disaster risk reduction is now well recognized worldwide. Indigenous knowledge “is increasingly being

seen as one of the critical components in reducing disaster risks at local levels, building resilient communities and sustainable livelihoods” (Trogrić & van den Homberg, 2018: 13). The indigenous early warning systems are essential for disaster risk reduction in rural areas as there is a growing literature that shows lack of uptake of official warning information about impending disasters. Ever since the emergence of vulnerability perspective in disasters, which “assumes that a real disaster occurs when it strikes an underprivileged population” (Donner & Rodríguez, 2011), the potential of integration between indigenous and scientific knowledge and the participation of stakeholders has increasingly been promoted by academia and international development and donor agencies (Dekens, 2007).

Indigenous Knowledge and International Agencies

Despite the increasing recognition and rapidly growing studies of indigenous knowledge in recent years and the emphasis on early warning systems to reduce disaster risks, there are not only inadequate studies on indigenous early warning systems, but they are also largely not integrated with the scientific knowledge and official early warning systems. The climate change community recognized the importance of indigenous knowledge on early warning system, and efforts are made to not only include but also integrate such knowledge for an effective disaster risk reduction system, particularly in rural areas.

The United Nations Office for Disaster Risk Reduction defines an early warning system as “An integrated system of hazard monitoring, forecasting and prediction, disaster risk assessment, communication and preparedness activities systems and processes that enables individuals, communities, governments, businesses and others to take timely action to reduce disaster risks in advance of hazardous events” and recommended “people-centered” early warning systems (“Early warning system,” accessed on 11 March 2022 at: <https://www.unisdr.org/terminology/early-warning-system>). The Paris Agreement on climate change not only recognized the importance of early warning systems, but it urged upon parties to the United Nations Framework Convention on Climate Change to “strengthen their cooperation on enhancing action on adaptation, taking into account the Cancun Adaptation Framework.” The Agreement recommended that “adaptation action should follow a country-driven” approach “taking into consideration vulnerable groups, communities and ecosystems, and should be based on and guided by the best available science and, as appropriate, traditional knowledge, knowledge of indigenous peoples and local knowledge systems, with a view to integrating adaptation into relevant socio-economic and environmental policies and actions, where appropriate” (UNFCCC 2015).

The Sendai Framework for disaster risk reduction of 2015 emphasizes, among others in priorities for action, the understanding of disaster risk reduction and the role of indigenous or traditional knowledge and highlighted the importance of involving indigenous people (UNISDR, 2015). The Framework recognizes the role “indigenous peoples” can play, “through their experience and traditional knowledge,” and “provide an important contribution to the development and implementation of plans and

mechanisms, including for early warning.” It recommended “a broader and a more people-centred preventive approach to disaster risk,” in which “governments should engage with relevant stakeholders,” including indigenous peoples “in the design and implementation of policies, plans and standards.” It recognizes the complementary role traditional or indigenous knowledge can play in the approach and decision in disaster risk reduction and observes that “Indigenous peoples, through their experience and traditional knowledge, provide an important contribution to the development and implementation of plans and mechanisms, including for early warning.” The Sendai Framework recommended thus: “To ensure the use of traditional, indigenous and local knowledge and practices, as appropriate, to complement scientific knowledge in disaster risk assessment and the development and implementation of policies, strategies, plans and programmes of specific sectors, with a cross-sectoral approach, which should be tailored to localities and to the context.”

Indigenous Knowledge on Early Warnings

There is no dearth of indigenous knowledge in different spheres of human life among indigenous and other communities. Their knowledge on early warnings is learned through “phenomenological experience.” There are various stories emerging in different parts of the world where indigenous communities utilize their local knowledge on early warning signs and escape major disasters. Here four cases or incidents of disasters are examined to explain how indigenous knowledge on early warning systems is in fact saving the community from disaster.

1970 Bhola Cyclone

The 1970 cyclone in the then East Pakistan, and now Bangladesh since 1971, is so far the deadliest tropical cyclone on record with 300,000 deaths and some estimated to as many as 500,000 lives lost. Since then huge resources were geared toward the establishment of national warning systems and to build cyclone shelters. For instance, the Red Crescent Cyclone Preparedness Programme played an important role in the installation of radio networks and trained volunteers. However, a study shows that “household preparedness and survival potential appear to be very much dictated by economic and social circumstance. Cyclone shelters and other protective/enabling infrastructure are still scarce on the chars and in the most rural coastal districts... which are extremely vulnerable to cyclones and tidal surges,” despite huge investment for building cyclone shelters and setting up of national warning systems (Howell, 2003: 4).

In her study of the “indigenous early warning indicators of cyclones” in Bangladesh during the 1970 cyclone, which were mostly derived from animal behaviors and weather patterns, Philippa Howell (2003: 2) observed that in such areas the “poor people are more likely to live in marginal, low-lying areas most prone to flooding” and “the poorest are least likely to hear radio warnings or understand the meaning of different warning signals.” Howell reported that the uneducated people are most likely

to feel alienated from a scientific system, and more so are the women “due to the purdah system.” In such condition indigenous early warnings are essential for early action. Muhammad Nurul Islam narrated: “I know there are Disaster Signals ranging from Signal No. 1 to 10, but I have no idea what they mean. I can predict any disaster coming when the sky turns gloomy, bees move around in clusters, the cattle become restless and the wind blows from the south” (Howell, 2003: 4).

In the case of the 1970 cyclone, the natural disaster occurred at the middle of the night, and some local indicators such as weather and sea or river patterns would not be visible few hours beforehand. However, other indicators particularly from the behaviors of animals occurred about a week before the disaster struck. For instance, a septuagenarian Muhammad Abdul Ali Majhi said: “We take notice of continuous crying of the dogs, increase of flies and mosquitoes, movement of ants, crying of kurpals, hot and humid weather and so on. These signs occur about 5-7 days earlier.” An octogenarian Bibi Sahera Khatun also confirmed this when she said: “The dogs had been howling for four days before the flood hit in 1970.” Despite the deadliest tropical cyclone on record with 300,000 deaths, those giving the information of the local indicators survived despite their marginality and vulnerability. Howell’s study found out that older people have “knowledge of local warning indicators based on animal behaviour or natural phenomena” and largely not transmitted to younger generations and regarded as unscientific.

Floods and Draughts in Malawi

Malawi, in the Sub-Saharan Africa, is one of the least-developed countries in the world with an economy heavily dependent on agriculture. With a largely rural and rapidly growing population, the landlocked nation is highly prone to natural disasters. In recent decades there is an increase in frequency, intensity, and magnitude of these calamities, especially floods and droughts, “and have adversely impacted on food and water security, water quality, energy and sustainable livelihoods of most rural communities” (DoDMA, 2015: viii). Malawi is also frequented with heat waves, strong winds, dry and cold spells, hailstorms, thunderstorms, landslides, mudslides, earthquakes, pest infestations, disease outbreaks, and fires.

Earlier Malawi had relied totally on indigenous early warning systems in preventing disasters or reducing disaster risks. These systems were developed by communities predicting upcoming disasters through various signs and indicators locally observed. In recent decades there are scientific early warning systems at the national level, as well as a number of community-based early warning systems which are implemented across the country by nongovernmental organizations, often in cooperation with local governments. However, the early warning systems operating in Malawi are inadequate. Despite recent efforts by different stakeholders in improving the existing early warning systems in Malawi, there are still a number of gaps. Studies indicated that “the existing early warning systems for floods, dry-spells and droughts are not providing an accurate warning information in a timely manner. In addition, the existing EWS in the country does not take into account the rich indigenous knowledge held by community members” (Troglić &

van den Homberg, 2018: 7). The National Disaster Risk Management Policy of Malawi in 2015 included the “development and strengthening of people-centred early warning system” in its policy priority areas (Government of Malawi, 2015: 5).

There are two main categories of ecological indicators which could be used as early warning signs: the changes in the behavior of animals and plants. In Malawi the most common early warning sign of heavy rain, which eventually leads to flood, is the behavior of ants. Before heavy rain the ants become very active and move around in large numbers in farms and even disturbing villagers in their homes. The same behavior is also observed among insects such as spiders and mosquitoes. Likewise various birds are also “found in increased numbers of producing a specific, loud sound are seen as indicators of heavy rainfall.” Heavy rainfall is also indicated by movements of pythons, grasshoppers, rats, cats, and other animals. The behavior of hippopotamus is an interesting indicator of not only heavy rains but also the extent of the upcoming floods. In their study Trogrlić and van den Homberg (2018: 34) indicated: “The hippo will move away from the water and walk for more than a kilometer on dry lands. These animals also give us an understanding on how the floods will behave. Every place where the hippo passes through, it is exactly the place where the floods will reach. Where the hippo did not go, the floods will not reach those lands.” Trees were also seen as an important indicator of heavy rainfall among various communities in Malawi. The bountiful flowering and bumper fruits borne by trees are the two ecological indicators.

There are also various early warning signs that communities draw from meteorology, particularly on forecasting floods, by sensing the temperatures, the pattern of wind blow, and intensity of rainfall. Very hot temperatures are indicative of higher amount of rainfall, while the wind direction is also believed to be indicator of heavy rain and flood. Local communities were aware of the impending flood by monitoring and reading the intensity of rain. For instance, a person from Khungubwe said: “For floods we do not focus on the cloud or wind but on the intensity of the rain” (Trogrlić & van den Homberg, 2018: 35). The communities are aware that flood will occur after several days of rain and monitoring the intensity of rain can predict upcoming flood and prepare in advance to minimize the impacts.

In the case of draught and dry spell too, there are several ecological indicators embedded in the local knowledge of communities. The indicators are broadly the changes in plant behaviors, such as cassava giving lower yield than normal, certain trees shed all their leaves, and bush grass dries. Several studies identify the gaps in the early warning systems and suggested integration of indigenous knowledge with scientific knowledge (Chiota et al., 2017; Trogrlić & van den Homberg, 2018). People-centered early warning systems are crucial for disaster risk reduction in countries such as Malawi.

In similar developing areas like Majuli river island in the Indian state of Assam, residents “are living in consonance with nature” and not only have several traditional adaptation practices to cope with frequent floods and riverbanks erosions of the Brahmaputra river, but “their traditional wisdom helps them to detect and identify the possible hazards or disasters.” They have the indigenous knowledge of early warning system predicting heavy rain and flood “which they observed through some signals from nature before any major event is about to happen which assists them to

prepare from disaster and reduce its impacts and the communities have mastered these over the years.” They also have the “coping mechanism developed by communities” such as storage of food grains and housing structure which “were based on their folklore or stories which are passed from one generation to another that were useful in understanding nature and the causes of disasters.” A village leader from Jengrai Gaon responded to Chetry (2020: 21):

We have our own flood predictions techniques and we observe sets of early warning sign which help us to predict the intensity of flood. Like the soil sediments coming downstream from which we get an idea of how heavy the rains would be. If soil sediments are flowing in the river before the onset of monsoon, it signals that flood will come and the rain would be heavy leading to floods.

Smong in Simeulue Island, Aceh, Indonesia

The Indian Ocean earthquake and tsunami on 26 December 2004 killed more than 200,000 people. The intensity of earthquake was the third-largest ever recorded magnitude with its epicenter between Simeulue and mainland Sumatra, about 40 km from the northernmost tip of the Simeulue island. The earthquake created a series of massive tsunami waves surging vertically up to 30 m (100 feet) high and caused huge damages to life and property in the surrounding coasts of the Indian Ocean affecting about a dozen countries. However, in Simeulue island in Aceh, there were only 7 deaths from a population of 78,128 people (The population figure is as per the official recorded in 2000 census). Studies show that people escape such a massive tsunami through the local knowledge of early warning system called *s mong*. The term is derived from “Devayan language word of ‘Kemong’ or ‘Seumongan’ which means ‘splash of water’ or ‘tidal wave or tsunami’,” and it “is used for tsunami warning when big earthquakes occur in Simeulue Island” (Syafwina, 2014: 573). In simple words it refers to “the ocean coming onto the land” (McAdoo et al., 2006: S665) and warns everyone of the incoming high tidal waves or tsunami and instructs them to run for higher grounds.

The story of *s mong* went back to more than a hundred years ago when a 7.8 magnitude earthquake hit the Indian Ocean on 4 January 1907 causing a tsunami that wreaked havoc killing about 70% of the total population in the island. Survivors of this tragic disaster passed on their experiences orally “to the next generation through buai-buai (lullaby) in family daily lives, nafi-nafi (advices) from old generation to the youth and through traditional poems and songs called Nandong that are performed in communal events in Simeulue.” One of the popular Simeuluean songs on smong is reproduced below (Syafwina, 2014: 576):

*Enggelmonsaocurito
Inangmasosemonan
Manoknopsaofano
Uwilah da sesewan
Unen ne aleklinon
Fesangbakat ne mali
Manoknopsaohampong
Tibo-tibomawi*

*Angalinon ne mali
Uweksuruiksahuli
Maheyamihawali
Fano me singatenggi*

Please listen to this story
One day in the past
A village was sinking
That what have been told
Starting with earthquakes
Following by giant wave
Whole the country was sinking
Immediately
If the strong earthquake
Followed by the lowering of sea water
Please find in hurry
A higher place

Smong has become a “part of the Simeulue indigenous culture, transmitted through songs, short poems, lullabies, and stories” and is “a key word understood by the entire population of Simeulue that describe the occurrence of giant waves after a major earthquake.” During the 26 December 2004 tsunami, the indigenous knowledge of *smong* was to a great extent successful in giving early warning leading to “a massive evacuation of the entire Simeulue beach area within a few minutes after the earthquake” (Suciani et al., 2018: 1).

Halo in Kuki Indigenous Knowledge

The Kukis are indigenous transborder community settling in the Indo-Myanmar and Indo-Bangladesh borderlands. They are endowed with rich cultural heritage including traditional knowledge on environment and ecology, meteorology, forestry, traditional agriculture practices, medicinal plants and herbs, and distinct social values and a “democratic check and balances” system in their traditional governance. (Kukis are indigenous people settling in the Indo-Myanmar borderlands. To know more about them, read Haokip (ed.). The Kukis of Northeast India (2013); and a further reading on their chieftainship form of governance and its democratic elements can be found in Haokip (2022: 10–11).) They have indigenous knowledge of early warning systems and make predictions, and such indigenous knowledge were handled down from generation to generation. The traditional meteorological knowledge has been useful for predicting weather and climate, and, like other indigenous communities around the world, such forecasting is used “as a guide in making important decisions that enable them cope and adapt to climate change-induced extreme weather variation” (Balehgn et al., 2019). Combined with such knowledge is the utilization of societal values in community-based resilience building. In this process people of the same community are brought together, and they collectively manage a disaster by discovering “their culturally resilient values, stories, memories and connections in their life for the purpose of understanding their identity and

becoming resilient. The activities also promote self-discovery and reflection, understand their own identity, manage change and transition, and build the skills necessary to become resilient.” The Kukis have the cultural value systems called *Khankho* and *Tomngaina*, which “instruct the youth and their social institutions to act in times of disaster, conflict, war and other calamities” (Haokip, 2018: 282–283). These social values help them to not only cope with disaster but also build a strong indigenous post-disaster recovery system.

On 20 June 2020, a halo was observed in the Indian state of Manipur. Social media were flooded with the picture of the 22° halo which has a colored ring. According to the Kuki traditional knowledge, it is a sign that there will be heavy rains and floods in the near future. In some other societies, there is a saying that “ring around the moon means rain soon.” Halo is an atmospheric optical phenomenon which is the result of either the sun or moon shining through thin clouds which contain millions of tiny ice crystals. The phenomenon is “due to the refraction of light that passes through the crystals, or the reflection of light from crystal faces, or a combination of both effects. Refraction effects give rise to colour separation because of the slightly different bending of the different colours composing the incident light as it passes through the crystals” (Fig. 1) (Britannica, “Halo,” accessed on 29 March 2022: <https://www.britannica.com/science/halo-atmospheric-phenomenon>).

Halo basically occurs due to high moisture content in the atmosphere. There is truth in such prediction by indigenous peoples “because high cirrus clouds often come before a storm” (What causes halos? EarthSky, Accessed on 31 March 2022 at: <https://earthsky.org/nature/what-causes-halos>)

Fig. 1 A picture of halo on 20 June 2020 in Manipur, India

Fig. 2 A picture of flood in Jildung or the Irl river in Saikul subdivision in Manipur

earthsky.org/space/what-makes-a-halo-around-the-moon/). Storm is normally followed by heavy rain, and incessant rain leads to flood. Within a month since the occurrence of halo in the state of Manipur, there was incessant rain in some parts of the state, and on 14 July 2020, the river Jildung, or the Irl river, overflowed the banks, and several acres of paddy fields were flooded and destroyed. These two incidents, of a halo and flood, not only prove that indigenous knowledge on early warning systems are reliable today, but they are best suited to rural masses who fail to read and understand modern systems or a far-flung area where modern communication systems could not reach them easily. A news report on 16 Jul 2020 also informed about mudslide at Moulding village, near Leimakhong bazaar under Kangpokpi district in Manipur due to incessant rain (Fig. 2) (Imphal Free Press, “Villagers living under fear of landslide in Manipur,” 16 Jul 2020, accessed on 23 February 2022 at: <https://www.ifp.co.in/1279/villagers-living-under-fear-of-landslide-in-manipur>).

Conclusion

Early warning systems are important component for disaster risk reduction. In recent years the importance of indigenous early warning systems is increasingly recognized, and integration of such knowledge with the scientific early warning systems is emphasized. Studies in recent decades have shown the existence of a largely ignored

but huge body of indigenous knowledge on early warning systems which were preserved for generations. Such local knowledge came to light only after their successful utilization in saving lives in major disasters around the world. Today international agencies recognize the indigenous early warning systems and encourage the integration of the indigenous early warning systems with the scientific systems for a more effective early detection of disasters and thereby to reduce the impacts of disasters. Earlier I argued that “Such integration would help the indigenous communities in understanding scientific knowledge better and develop an integrated approach to community based disaster risk reduction and resilience building” (Haokip, 2018: 296). Despite such recognition, efforts by climate change community to integrate the traditional knowledge and scientific knowledge on early warning systems for an effective disaster risk reduction system are slow and tardy. For an affective early warning system, the focus should go beyond a mere integration of indigenous and scientific early warning systems; it should be people-centered, which is crucial for reducing disaster risk.

Abstract

The success of institutional preparedness against disasters lies in minimum casualty, which is largely dependent on the resilience of a community and the ability of its government to work synchronously. Odisha, a relatively small and economically weaker state on the east coast of India exemplifies how institutionalization, inclusive strategy, and its prudent implementation can make the turnaround. In the year 1999, the Super Cyclone left about 20,000 people dead in Odisha! After a decade in 2013 when cyclone *Phailin* struck Odisha, the state carried out India’s biggest-ever evacuation with about 5 lakh people moved up to safe cyclone shelters within a span of 48 h, resulting in “zero human casualty”!

P. Harichandan (✉)

e-mail: pradeepharichandan@cedindia.org

More than a decade of meticulous planning, institution building, and community engagement helped manage every successive disaster with more professionalism, precision, and faster response. In 2020, when cyclone *Amphan* battered West Bengal amid the Covid-19 pandemic, Odisha played a major role in the rescue and restoration operations in Kolkata and adjoining areas. Not only managing calamities but also Odisha recorded a spectacular performance in managing the Covid-19 pandemic. Starting with a low resource base and relatively weak infrastructure, the state could build up a massive health infrastructure, trained manpower, and effective response system within a record time! It could supply oxygen to save lives in far-off Delhi and Mumbai!

This chapter showcases Odisha's success in building a strong disaster-resilient ecosystem and suggests how achieving next-level disaster preparedness requires a change in approach; concerted effort for institutionalization, inclusive strategy, and community engagement.

Keywords

Inclusive · Resilience · Zero-casualty · Bounce-back · Skill-matrix · Eco-system

Introduction

As the world struggled to overcome a deadly disaster in recent human history in the form of COVID-19 and its variants, the discourses and practices on disaster preparedness also needed to be more inclusive, strategic, and institutional. The keys to a robust disaster management plan are inclusive strategy and institutionalization that work on the built-in mechanisms of decentralization, community empowerment, and ownership. The success of disaster preparedness lies in the resilience of a community and the ability of the government to forge strong bonds institutionally for overcoming varieties and volumes of disasters – cyclones, floods, drought, earthquakes, tsunamis, heat waves, or even a pandemic, in a planned and prudent manner.

Odisha: a Disaster Vulnerable State

The topography of Odisha makes it a disaster-prone state. The state has a long history of disasters – cyclones, floods, and droughts. Between the years 1891 and 2021, more than 100 tropical cyclones have lashed Odisha, which happens to be the highest number among the coastal states of India. The state has 30 administrative Districts, which can be classified into the coastal strip, the western region, and the central plateau. Frequent floods and cyclones ravage the coastal districts that lie along the Bay of Bengal with 485 km. long coastline while recurring droughts haunt the western and central parts. Over the Bay of Bengal, tropical cyclones travel upward in the northwest direction.

Because of the physical shape of the subcontinent, storms mostly spin in the anti-clockwise direction. Odisha, located at a critical curve of the Indian subcontinent gets frequently exposed to pre- and post-monsoon cyclones (Ramesh, 2019).

Propelled by a severe drought in the year 1865, the “Orissa Famine” of 1866 continues to be remembered as a mass tragedy for the people of Odisha over generations. Though it affected the entire east coast of India from “Madras” to “Calcutta,” the impact was most severe in “Orissa.” About one third of the population got wiped out during and in the aftermath of the famine (Imperial Gazetteer of India vol. III, 1907). The response of the British government officials to tackle this massive human tragedy was marred by carelessness, indifference, absolute lack of empathy, and miscalculation. The British bureaucratic apparatus made an incorrect and fictitious assessment of the situation. As a result, by the time the imported rice could reach the affected region in September 1866, lakhs of people had already died of starvation. Many more were killed by cholera during the monsoon and by malaria afterward. At least one million people, about one third of the population died by the end of the year. Many more died over the next 2 years (Patel, 2016). The British Raj blamed it on delayed shipments of rice owing to adverse weather conditions in the sea, weak surface transport network, and distribution system. However, lack of community “connect” and “misgovernance” by the colonial government was clearly the prime reasons for this mass tragedy.

After more than a century, in the year 1999, Super Cyclone devastated the entire coastal Odisha with about 1.6 million homes razed, 20,000 people dead, thousands of animals killed, plants uprooted, and property damaged to the tune of US\$ 4.44 billion! No doubt, the Super Cyclone was unprecedented and unparalleled in the cyclone history of the country with the state capital Bhubaneswar itself (from where the rescue and relief operations were to be carried out) being ravaged and remained cut off in darkness for more than a week. Almost every house, including that of the Chief Minister’s official residence was blocked by fallen trees, broken electricity poles, and razed boundary walls, and it was not humanly possible to get out of the homes. It took months and years for an economically weak state like Odisha to recover from the socioeconomic impact of the catastrophe. But, the major reason for failure to prevent such massive loss of lives and properties and inadequate post-cyclone relief and rehabilitation works were more systemic than eventual. Lack of institutional preparedness, political rivalry, and bureaucratic failure led to an inadequate and delayed response to the catastrophe. Neighboring Andhra Pradesh Government was the first to come to the rescue of the people of Odisha by restoring the communication system. International aid agencies contributed immensely to the relief and rehabilitation work. Besides, it was a time when the scope of disaster preparedness was limited to the “Orissa Relief Code” framed after the 1977 cyclone and finalized in March 1980. The concept of disaster management was not prevalent in the country at that time and it served only as an operational guide for post-calamity relief operations.

Incorporating Lessons Learnt from Super Cyclone 1999

After the Super Cyclone of 1999, there has been a clear and decisive change in the approach of the authorities regarding their scope of work from only post-disaster response to regular and continuous pre-disaster preparedness, rescue, and restoration through dedicated agencies and specialized forces. In fact, there was a lot to learn from the massive loss of lives and properties, and the catastrophic socioeconomic impact of the 1999 Super Cyclone that led to a serious rethinking of the way a disaster should be approached and managed. As a result, 14 years later in the year 2013, when cyclone *Phailin* struck Odisha, it was a different, much stronger, rapid, and institutionalized response with “zero casualty” outcome. In 2013, Odisha carried out India’s biggest-ever evacuation with about 5 lakh people being moved up to safe cyclone shelters within a span of 48 h! From here, the state has been trying relentlessly to reach the next level of disaster preparedness. While tackling cyclone *Yaas*, Odisha became the first state in India to evacuate about 4500 pregnant women to safe places for emergency medical assistance who gave birth to 750 babies safely under medical supervision during the cyclone on 26 and 27 May 2021. This could be possible for identifying and relocating such huge numbers of mothers to safe places, mostly hospitals or health centers. On 25 May 2021, when the evacuation process was still on, a heart touching visual came in the media from Odisha’s *Kendrapada* District. Without waiting for the rescue team, a school teacher, Mr. Durjay Moharana, at *Rangani* village in *Rajnagar* Block of the District, helped to carry an octogenarian lady to a safe place on his shoulder, though it was not part of his allotted duty. Many such stories of proactive community action keep coming from the state in the collective fight against disasters. Community pro-activeness and participation are a solid backbone for successful disaster management anywhere. Covid appropriate behavior was followed by all concerned and in spite of the massive evacuation of about 7 lakh people to safe places, there was no exponential rise of positive cases in the cyclone-affected Districts of Odisha. This was yet another feat of modern disaster management amid a pandemic.

Thus, the successive high floods and cyclones [*Hudhud* (2014), *Fani* (2019), *Amphan* (2020), *Yaas* (2021)] have been managed with greater success. The success story is not limited to rapid response with rescue and restoration operations in Odisha alone. The Special Forces from Odisha played a crucial role in immediate rescue operations, clearance of roads, and restoration of power and water supply in the city of Kolkata and adjoining areas devastated by the cyclone *Amphan* (2020).

Intricacies of Institutional Preparedness

The decade between the Super Cyclone and the *Phailin* was a decade of meticulous, long-term planning, institution building, and community empowerment that helped manage every successive disaster with more professionalism, precision, and less “bounce back” time. The creation of Odisha State Disaster Management Authority (OSDMA), Odisha Disaster Rapid Action Force (ODRAF), and the advent of high

accuracy cyclone warning technology contributed to the institutional preparedness against disasters (Mohanty, 2021).

Odisha State Disaster Management Authority (OSDMA)

Odisha became the first state in India to come up with a systemic and institutional response by constituting an autonomous body for disaster management on 29 December 1999, just within 2 months' time of the Super Cyclone! On 29 December 1999, Odisha State Disaster Mitigation Authority (later renamed as Odisha State Disaster Management Authority - OSDMA) was set up as an autonomous organization registered under the Societies Registration Act, 1860.

Unlike typical government departments, OSDMA has been built to function as a techno-managerial and professional front organization. The decision-making and approval processes, which would otherwise go through multiple layers of the hierarchy thereby delaying implementation, have been done on a fast-track channel with support from technology and modern management practices.

The broad objectives of OSDMA have been to build up a robust disaster risk management system, coordinate disaster response and recovery operations and develop strong climate change adaptation capabilities to ensure a disaster resilient state. The specific objectives of OSDMA have been to:

- (a) Promote disaster preparedness at all levels in the state.
- (b) Act as the nodal agency for disaster reconstruction works.
- (c) Coordinate with the line departments involved in reconstruction.
- (d) Coordinate with bilateral and multilateral aid agencies.
- (e) Coordinate with UN agencies, international, national, and state-level NGOs.
- (f) Network with similar and relevant organizations for disaster management.

The first and foremost challenge during and in the immediate aftermath of the Super Cyclone of 1999 was a total failure of the communication system at all levels for which rescue, restoration, and relief works could not be coordinated for about a week. Therefore, learning from the past, developing a robust communication system became imperative. By the year 2004, OSDMA had set up a very high frequency (VHF) network all over the state, linking 401 locations covering all District headquarters, tehsils, Blocks, and vulnerable Gram Panchayats of the coastal belt. Satellite phones were deployed at strategic locations to keep the channel open in the event of total failure of the communication network. The UNDP provided initial technical support for use of the Geographical Information System (GIS) in disaster management. A dedicated GIS Cell became operational in collaboration with the Odisha Space Applications Centre (ORSAC) to be used for rescue, restoration, and reconstruction work.

District Disaster Management Centres (later merged with the District Disaster Management Authority) were established as the district level nodal agencies to drive all disaster preparedness, rescue, and restoration operations in an affected District. It

was well equipped with trained personnel, a state-of-the-art communication system, and a strong logistic support base. OSDMA has a Disaster Management Training Cell (DMTC) set up at Revenue Officers' Training Institute (ROTI) in Bhubaneswar for imparting special refresher training to the ODRAF and Fire Services personnel.

Odisha Disaster Rapid Action Force (ODRAF)

Though OSDMA and the District Disaster Management Authorities became the nodal agencies for disaster management planning, preparedness, rescue, restoration works, and the interface points for collaboration with other national and international entities, raising a special ground force was imperative. A high-skilled force equipped with state-of-the-art technology to assist the civil administration in rescue, restoration, and relief operations on ground zero was felt necessary. In this context, the Odisha Disaster Rapid Action Force (ODRAF) was raised on 7 June 2001 drawn from the Orissa Special Armed Police, Armed Police Reserve, India Reserved Battalion, and Specialized India Reserve Battalions.

ODRAF is structured as a lean force having 20 units stationed at strategic locations with only 50 personnel per unit. The proficiency and agility of ODRAF units in responding to crisis situations have made it a formidable and pre-disaster preparedness post-disaster response force. Multi-skilling and extra-agility of the ODRAF have come through its operational interface with the Indian Army, Indian Navy, Indian Air Force (IAF), Indian Coast Guard, National Disaster Response Force (NDRF), and Odisha Fire Services.

The ODRAF units are deployed on the ground as per the requisition from the Special Relief Commissioner (SRC), OSDMA, or the District Collector concerned. It has been a normal practice for the Special Relief Commissioner/Managing Director of OSDMA to request the Inspector General of Police (Law & Order), who is in charge of the movement of the ODRAF, for deployment of ODRAF, which is nonnegotiable. Telephonic calls are also taken by the State Emergency Operation Centre/identified Nodal Officer in the OSDMA to mobilize the ODRAF teams at the earliest.

There is a Standard Operating Procedure (SOP) for movement, deployment, camp arrangement, equipment, logistics, etc. Effective interorganizational coordination with civil administration and line departments for managing high-intensity or large-scale disasters is ensured by the Head of each unit. Seamless interagency coordination has produced a very high level of operational efficiency of the force in all kinds of crisis situations.

Military type of training is imparted to the personnel of ODRAF with additional skilling on search, evacuation, rescue, relief, and restoration in the face of any type of disaster. The cost of specialized training is borne by the OSDMA. A full-fledged specialized Disaster Response Training Guidelines has been developed on the basis of input from all levels. An annual training calendar is prepared every year taking into consideration the types of training, availability of training slots in State and National level training institutions, and non-disaster lean period. The modules are

based on the roles and responsibilities of different categories of personnel. After completing the first two levels of training internally, ODRAF personnel are sent to the reputed training institutions in the country for specialized training and *Training of Trainers* (TOT) courses. The entire training program is curated into the following levels of courses:

- (a) Basic/Induction level Training Course (internal);
- (b) Advanced/ Specialized Course (internal);
- (c) Specialized and Training of Trainer's Courses (external).

A skill matrix has been developed for identification and enhancement of the skillsets and efficiency levels of the ODRAF personnel in disaster response activities, which has been ISO 9001-2000 certified. The entire disaster response activities are divided into a number of skill groups depending on their possible application in different disaster situations such as water rescue, search and rescue from collapsed structures, relief line clearance, transportation line clearance, communication restoration, power restoration, casualty management, and miscellaneous responses. The skill matrix is initially prepared with the self-assessment of the personnel on their knowledge on the use of different categories of equipment. The proficiency of individual personnel in using each piece of equipment is measured on a numeric scale.

Skill-group-wise joint mock drills are carried out at regular intervals to enhance the proficiency of a particular group of ODRAF personnel in emergency operations and for cross-learning. These joint mock drills are conducted also for giving exposure to the ODRAF personnel with the personnel drawn from other specialized agencies such as the National Disaster Response Force (NDRF), State Fire Service, Civil Defense, St. John Ambulance, Red Cross, East Coast Railway, Airport Authority of India, and other stakeholders.

Odisha Fire Services

Odisha is also an example of how a pre-independent state fire services force can be re-equipped and re-skilled for the additional job of rescue and restoration operations in times of disasters in and outside the state. Odisha Fire Service has got the dual mandate of firefighting as well as disaster response. After the Super Cyclone of 1999, each Fire Station in the State was redeveloped as a multi-hazard disaster response unit to respond in case of any type of disaster, in addition to its original firefighting and rescue operations. It took about a decade to re-equip and re-skill the 5000 odd personnel of 338 fire stations in the State.

Odisha Fire and Disaster Response Academy (OFDRA), Bhubaneswar

The training of Odisha Fire Services personnel began in the year 1943 with Mr. Hetch Blue, the then Deputy Fire Officer, Odisha Fire Service taking charge of the training establishment. In the year 2003, the Government of India recognized

Odisha Fire Services Training Institute (OFSTI), Bhubaneswar as the Regional Training Centre (RTC). In the year 2015, Govt. of Odisha upgraded the OFSTI into Odisha Fire and Disaster Response Academy (OFDRA). Till September 2020 more than 26,000 personnel were trained from OFDRA.

Odisha Fire and Disaster Response Institute (OFDRI), Naraj, Cuttack

Odisha Fire and Disaster Response Institute (OFDRI) was established at Naraj, Cuttack in the year 2015 for the training of the auxiliary fire force of Odisha Fire Service consisting of Firemen, Leading Firemen, Drivers, and Havildars, thereby decongesting the OFDRA and specializing both OFDRA and OFDRI. However, the training modules of both OFDRA and OFDRI are curated to equip the personnel as a multi-disaster response force with the ability to approach and face any emergency.

Keeping “Community” at the Core

A disaster-resilient community is understood to be less vulnerable and more prepared to manage sudden catastrophes such as fire, flood, cyclone, earthquake, landslides, bomb blasts, nuclear accidents, epidemics, and pandemics. Although disaster resilience at the community level is somewhat missing from the public discourse and there has been no direct mention of it in disaster management planning at any level, it is indeed a determining factor for the success or failure of any disaster management operation. Only an empowered community can be a disaster-resilient community that would make the governments prepared to manage disasters more effectively.

An empowered community constitutes a solid foundation for a disaster-resilient state or country. Governments become capable of managing disasters more effectively when the community takes ownership in creating, operating, and maintaining community infrastructures like toilets, cyclone shelters, *anganwadi* centers, shelter for the homeless, rental houses, hostels for working men and women, and water ATMs, which play a crucial role during and after the occurrence of a disaster. It becomes much easier for the city government to manage a disaster with ground-level support from an empowered and proactive community. Odisha has shown the way in empowering the community by involving them in all the above initiatives. Many such initiatives are taken to empower the community and if practiced elsewhere would be certainly helpful for building a strong community force to manage disasters.

Recognizing the indispensability of community engagement in disaster preparedness, the Community-Based Disaster Preparedness (CBDP) program was initiated in the year 2001. Disaster Management Committees at the District, Block, and Gram Panchayat levels were set up during the UNDP-supported Disaster Risk Management Programme (2002–2009) as a stepping stone to community participation and decentralized planning. District Disaster Management Plans are prepared and updated every year by adopting a bottom-up approach, with input from the Block and Gram Panchayat levels. The *Sarpanch* heads the GP Disaster Management

Committee with members from the local NGOs and CBOs and other stakeholders. Similarly, the Block Disaster Management Committees and District Disaster Management Committees were set up headed by people's representatives. Later, as per the National Disaster Management Act, 2005, the District Disaster Management Committee was restructured as District Disaster Management Authority.

Odisha's long journey to disaster preparedness has been entirely community-driven. The practice of disaster preparedness at the panchayat level aimed to ensure the community's preparedness as the first line of defense during the crucial few hours before and after the disaster had struck, focusing on zero casualty and community participation in the restoration operation. It facilitated building up a strong and sustainable grassroots institutional mechanism for preparing multilevel inclusive strategies as part of the institutional preparedness against disasters.

Disaster Resilient Infrastructure

The new multipurpose cyclone shelters built up in the coastal stretches of the state under the National Cyclone Risk Mitigation Project (supported by the World bank) not only have space for the needy people to take shelter but also for their animals to be kept in the basement; as the latter is the source of livelihood for many. So, "zero casualty" not only of humans but also of animals become the next-level disaster management target for the state. During the non-disaster time, these multipurpose cyclone shelters are used as informal education centers; and the space is utilized for social benefits like holding awareness camps, health camps, etc. Hundreds of evacuation roads and bridges are constructed in strategic places to make evacuation and rescue operations easier. The commissioning of the community-level early warning dissemination system with last-mile connectivity has been the key to the rapid dissemination of information about the impending dangers of a disaster.

As part of a strategic plan, the state government has initiated land acquisition for the construction of the 382 km long proposed coastal highway along the Bay of Bengal (Bisoyi, 2021). Besides movement of relief and supplies during disasters, the coastal highway will serve as an economic corridor for the transport of agricultural and in-land fishery produces to the Paradip and Dhamra ports. The project is taken up under the Government of India's *Bharatmala Pariyojana*. The highway will bypass the Chilika lagoon and culminate at Digha touching Brahmagiri, Puri, Konark, Astaranga, Naugaon, Paradip Port, Ratanpur, Satabhaya, Dhamra, Basudevpur, Talapada, Chandipur, and Chandaneswar. In the first phase, land acquisition for approximately 177 km length of the proposed Tangi-Ratanpur stretch has been started, which will provide cyclone resilient connectivity to nearly 100 villages in Puri, Khurda, Jagatsinghpur, and Kendrapara districts.

As the Government of Odisha asks the Union Government to consider sanctioning Rs 25,000 crore for disaster-resilient power infrastructure in cyclone-prone coastal areas of the state, it becomes evident how the state has been approaching the creation of disaster-resilient infrastructure in the state in a planned manner.

Inclusive Strategy

Today, Odisha has become a lighthouse for others on how inclusive strategy and its prudent implementation can make the turnaround. Odisha exemplifies how a small and economically not so strong Indian state could develop a robust institutional capacity to manage disasters of any kind; whereas many others with a much larger resource base and government machinery have failed. The answer lies in strategic long-term planning and a prudent two-pronged approach (i) to nourish and involve the community in disaster preparedness on the one hand; and (ii) to establish and strengthen institutions for techno-managerial operations, ground-level infrastructure creation, and logistic support on the other.

However, framing of a high-voltage so-called “inclusive strategy” to be executed by a typical government bureaucratic setup has never succeeded anywhere. The road to the next level of disaster preparedness begins with a citizen-centric participatory government. The space for government–community interface must be real and wide enough to have rooms available for each citizen to participate in some or the other activity of local governance, directly or indirectly that would ultimately contribute to a disaster-resilient state or country.

Integrated Approach

The learnings from the COVID-19 management combined with Odisha’s experience in managing calamities also showcase an integrated approach and overarching operational framework with ample rule and role clarity for each stakeholder down to the level of an *Anganwadi* or *Asha* worker; and adherence to the SOPs by them without waiting for the official orders, which has made the response and bounce back times incredibly faster. The message is loud and clear – governments become capable of managing disasters more effectively when the community takes ownership in creating, operating, and maintaining community infrastructures like cyclone shelters, *anganwadis*, schools, community centers, and toilets which play a crucial role during and after the occurrence of a disaster. For instance, the key of a cyclone shelter is kept with the local *Sarpanch*, instead of any government official to respond instantly to an emergency need. It becomes much easier for the govt. to manage a disaster with ground-level support from an empowered and proactive community. Achieving the next-level preparedness in managing disasters with “zero casualty” and strong “bounce back” capacity requires concerted efforts for making disaster preparedness more inclusive and institutional with an empowered community and participatory government.

Odisha has recorded a spectacular performance not only in managing calamities but also in managing a widespread highly infectious pandemic with a very low death rate and high recovery rate in the entire country. Starting with a low resource base and relatively weak health infrastructure, the state could build up an effective response system within a short span of time, with high-impact IEC, community awareness, high test rate, efficient contact tracing, proper treatment, massive

infrastructure built-up, and trained manpower in terms of COVID hospitals and quarantine centers. The decision to delegate the power of the District Magistrate to all *Sarapanchs* in managing COVID 19 is historic indeed!

In fact, the rapid response mechanisms adopted by Odisha to deal with about 10 lakh migrant laborers who came back to their homes from different parts of the country post lockdown have been quite impressive. Registering and testing them in temporary camps after their arrival was meticulously planned and implemented to keep the domestic population insulated from the virus. These temporary camps, set up mostly in government and private educational institutions for each district, had a cumulative capacity of 800,000 beds. Besides, financial incentives were also declared for these people. To tackle the livelihood problems of the migrants and local urban poor, the Government of Odisha in the Housing and Urban Development Department implemented a tailor-made wage employment program called “Urban Wage Employment Initiative (UWEI)” in April 2020 at a cost of Rs. 100 crore for 6 months, which has been extended and continued further with more fund and dedicated UWEI Cells in all Urban Local Bodies.

By the time the first wave of Covid was over, Odisha had already built up a massive Covid response health infrastructure and team within a record time. The state was the first to establish one of the country’s biggest 1000-bedded dedicated COVID hospitals in a record time of just 1 week. Since then, Odisha has built up more than 50 dedicated Covid hospitals, which included both public and private medical institutions. The entire medical expenses of Covid patients are borne by the state government. There has been a successful fund-raising initiative as well to meet Capex and Opex and other medical expenses from individual and corporate entities like Odisha Hydro Power Corporation, Odisha Mining Corporation, Mahanadi Coal Field, and Indian Oil as part of their CSR initiative. The state government has decided to spend about Rs 2000 crore for vaccinating those between 18 and 45 years of age free of cost. Covid testing capacity of the state increased from just 01 functional lab to 19 labs within a short span of time. The biggest initiative came up in setting up a vaccine production facility near Bhubaneswar in collaboration with Bharat Biotech to meet future vaccine requirement of the state on priority. When many hospitals in Delhi and Mumbai ran out of oxygen and relatives of patients ran from pillar to post for managing an oxygen cylinder, Odisha responded by supplying oxygen to different cities of the country to save lives and ensured unhindered transportation.

Effective monitoring and surveillance, testing, and contact tracing have been the key to successful pandemic management anywhere. To leverage technology, the state IT Dept. linked all Covid hospitals, testing facilities, quarantine centers, and cases with GIS-based information system. The Covid expert team prepared a 15-point SOP that included daily state-level public briefing by officials and experts keeping people regularly briefed, control room meetings, supervision, risk assessment, identification of high-risk areas, containment zone microplanning, etc. Daily and weekly reports are collected to track the trend for the next strategic decisions. The challenging task to train and build capacity of thousands of doctors, nurses, paramedics, AYUSH staff, police, frontline health and sanitation workers, volunteers

of ICU management, psychosocial training, etc., during the lockdown was supported by state government officials, WHO, and the UN agencies. Even though complaints of negligence have been reported from some places, which are unfortunate but natural in such a huge pandemic management, reports of human touch given by the medical staff to the patients like counseling, shaving their beard, combing their hair, and entertaining them by dancing to the tune of music are some good news heard nowhere else in the country.

The state government introduced bike ambulances with oxygen support for Covid patients in the inaccessible *Bonda Ghati* of *Malkangiri* District; and prepared itself for the subsequent waves by identifying and making dedicated Covid hospitals with specially trained staff ready to take care of children who are expected to be affected more severely. This is yet another instance of the next level of disaster preparedness.

Conclusion

As hurricanes, typhoons, and floods become more frequent than ever before with climate change, Odisha continues to strive for the next level of disaster preparedness. It sets precedence, for how institutional preparedness is the key to success, and institution building, inclusive strategy, integrated approach, and community empowerment can help the government to build up a robust and effective disaster management eco-system. True, governance, infrastructure, technology, logistics, and operational professionalism are also crucial factors in effectively managing disasters. But achieving the highest level of disaster resilience essentially depends on the extent of institutional preparedness and the ability of the government of the day to work synchronously with the community in a planned and prudent manner.

environmental disasters and climate change. Considering the acute threats faced by the coastal areas, the Ministry of Environment and Forest (MOEFCC), Government of India, gazetted the first Coastal Regulation Zone (CRZ) Notification in 1991 using the powers conferred under the Environmental Protection Act, 1986. The CRZ Notification of 1991 was superseded by the CRZ Notification of 2011, which was in turn superseded by the CRZ Notification of 2019. The chapter explores the role of the judiciary in administering and evolving an efficacious coastal regulation regime in India by analyzing judicial statements. In the Indian context, the judiciary has played a significant role in developing and incorporating legal principles based on international legal developments. The chapter evaluates the impact of judicial statements in building disaster-resilient coastal cities in India.

Keywords

Maradu · Coastal regulation · Environmental protection · Judicial statements

Introduction

India's extensive stretch of coast has been at the receiving end of unregulated developmental and human activities. (Sudha Rani et al., 2015). The threat is compounded by the indiscriminate developmental activities undertaken along the coasts challenging the attainment of sustainable development. The Supreme Court in the *Kerala State Coastal Zone Management Authority v. The State of Kerala Maradu Municipality*, popularly known as the *Maradu* case (Kerala State Coastal Zone Management Authority v. The State of Kerala Maradu Municipality, 2019), while directing the demolition of waterfront apartment complexes built on the coastal zone of Kerala's Maradu, observed that the devastating floods faced by Uttarakhand and Tamil Nadu are the direct results of construction sprees on river banks and the resultant emaciation of the natural path of backwaters. The judgment has been hailed as momentous for coastal regulation and has set a new stickler standard in environmental adjudication in India. At the same time, an analysis of the rationale employed by the court in ordering the demolition raises certain legal concerns. Mapping through the judicial statements, the chapter explores the role of the judiciary in administering and evolving an efficacious coastal regulation regime in India. The chapter evaluates the impact of judicial statements in building disaster-resilient coastal cities in India. Section "[Maradu – Facts, and History](#)" elaborates the facts, procedural history, and the decision rendered in the *Maradu* case. Section "[Legislative Framework on Coastal Regulation](#)" briefly discusses the legislative framework on coastal regulation to contextualize the *Maradu* case and map the major thread of judicial decisions to regulate coastal zone. Section "[Maradu Case Impact on Environmental Jurisprudence](#)" looks into the specific implications of the *Maradu* decision on environmental jurisprudence.

Maradu: Facts and History

Rarely is the conclusion of an environmental case broadcasted on live TV (NDTV, 2020). Rarely do environmental cases lead to the making of a movie (Shibu, 2020). The *Maradu* case is peculiar in both facts and law. The *Maradu* case has its origins in a letter dated May 18, 2007, by the Secretary of the Local Administration Department, Government of Kerala, directing the Secretary Maradu Grama Panchayat, to cancel the building permits of five apartment complexes that were allegedly in the violation of Rule 16 of the Kerala Municipality Building Rules. The secretary, Maradu Grama Panchayat, issued a show-cause notice for the revocation of the building permits that were granted to the five builders. In response, the builders moved five different writ petitions before the High Court of Kerala (Alfa Ventures Pvt. Ltd. v. Government of Kerala & Others, 2007) (M/s Holy Faith Builders and Developers Pvt. Ltd. v. Government of Kerala and Ors, 2007) (M/s. Jain Housing & Construction Ltd. v. Maradu Grama Panchayat, 2007) (K.V. Jose v. Government of Kerala, 2007) (M/s. Holiday Heritage (P) Ltd v. Government of Kerala, 2007). Even though the cases were filed, admitted, and the injunction orders passed in 2007, the final judgment was passed only on September 10, 2012, i.e., it took five long years for the High Court of Kerala to dispose of these cases, and the corollary being that the interim injunction on the cancellation of building permits continued for five long years. In this interregnum, apartment complexes were fully constructed and sold to unsuspecting buyers. While things were so, the Maradu Panchayat was made the Maradu Municipal Corporation in November 2010 (Kerala State Coastal Zone Management Authority v. The State of Kerala Maradu Municipality, 2019).

It is relevant to note that in the final judgment dated September 10, 2012, the single bench of the High Court of Kerala adjudicated the entire issue on the administrative law prohibition of statutory authorities from acting under dictation and did not even find it relevant to refer to any principle of environmental law let alone the Coastal Regulation Zone (CRZ) Notification. It is also relevant to note that the Kerala Coastal Zone Management Authority (KCZMA), which was to later move the Supreme Court of India and secure the order of demolition, impleaded itself in just one (Alfa Ventures Pvt. Ltd. v. Government of Kerala & Others, 2007) of the five cases brought by the builders before the single bench. The single bench decided the matter based on the administrative law prescription of a governmental authority acting under dictation and a lenient view taken by an earlier judgment (Baiju. K. v. Government of India, 2011) of the High Court of Kerala in regularizing errant constructions.

Maradu Municipality appealed this order of the single bench before a division bench of the Kerala High Court, and the KCZMA was made the Second Respondent (Maradu Municipality v. State of Kerala and Others, 2013). The judgment delivered by the division bench specifically records the arguments made by the KCZMA to the effect that Rule 23(4) of the Kerala Municipality Building Rules, 1999 (hereafter KMBR, 1999) requires all constructions to comply with Coastal Regulation Zone notifications (hereafter CRZ Notifications) and that all building permits and plans require the clearance from the KCZMA. The court rejected both these arguments by

stating that the Coastal Zone Management Plans (CZMPs) remain unusable and that the delinquency of the municipality in not forwarding the building permit/plan to the KCZMA cannot be used for penalizing the builders. The division bench ends the judgment with the following lines:

Before parting with these cases, we must record our anguish about the manner in which the appellants have conducted themselves. They were merrily issuing permits and allowed the builders to proceed with the constructions. After substantial progress was made, the Municipality suddenly became wiser on receipt of the letter from the GovernmentGovernment. (*Maradu Municipality v. State of Kerala and Others, 2013*)

At the heart of this controversy is the interpretation of Rules 16 and 23(4) of the Kerala Municipality Building Rules, 1999 (Government of Kerala, 1999). The division bench essentially held that the revocation of the building permit for the alleged violation of CRZ norms could not be brought under Rule 16 of the Kerala Municipality Building Rules, 1999, because such a violation is not covered by any of the four instances envisaged in the provision, namely, “the permit was issued by mistake,” “a patent error has crept in it,” “issued on misrepresentation of fact or law,” or it will amount to a “threat to life or property.” This particular division bench judgment brings home the tragedy that is wrecked when ultra-positivist interpretive techniques are trained on environmental cases. Against this judgment of the division bench, the KCZMA preferred a review petition before the High Court of Kerala; however, it was dismissed (2015).

The KCZMA took the case in appeal before the Supreme Court of India through a Special Leave Petition Order dated 27/11/2018 in SLP(C) No. 004227 - 004228 / 2016 making the State of Kerala the first respondent and the Maradu Municipality the second respondent. During the course of the hearing, the Supreme Court categorically found that there is no discussion or pronouncement from either benches of the High Court of Kerala as to the exact Coastal Regulation zoning (CRZ Category III, Category I, or Category II) of the impugned apartment complexes. The Supreme Court appointed a committee consisting of three bureaucrats to hear the objections and was asked to report in 2 months as to the precise coastal zoning and the legality of the impugned constructions in terms of CRZ Notification 1991. (*Kerala State Coastal Zone Management Authority v. The State of Kerala Maradu Municipality, 2019*) Upon receipt of this report and hearing both the parties, the Supreme Court of India went on to overturn the judgments of both the single bench and the division bench of the Kerala High Court and held the constructions to be illegal (*Kerala State Coastal Zone Management Authority v. The State of Kerala Maradu Municipality, 2019*).

The single bench and the division bench of the High Court of Kerala adjudicated the matter entirely on the point of infraction of administrative law and not on environmental law. On the other hand, the Supreme Court was not concerned with administrative law infraction at all. The apex court decided the entire matter on

environmental law and the violation of the CRZ Notification. The specific factual finding in the judgment is to the effect that the constructions are in violation of the CRZ norms and that such constructions would affect the natural water flow and would lead to calamitous results. The court used the floods in Kerala, Uttarakhand, and Tamil Nadu in 2019 to substantiate its conclusions. It finds fault with the High Court for not taking into account the approved CZMP of 1996. In fact, it relies on the same CZMP of 1996, which the High Court's division bench found unusable, to order the demolition of the apartment complexes. The apartment complexes were brought down using controlled explosions on January 11 and 12, 2020. By ordering the demolition of these apartment complexes in *Maradu*, the Court has set a new stickler standard in environmental adjudication. In order to properly assess the context of the *Maradu* case and its implications, it is essential to understand the legislative framework relating to coastal regulations in India and the role played by the judiciary.

Legislative Framework on Coastal Regulation

The CRZ Notification 1991 was promulgated by the Ministry of Environment and Forest (MOEFCC) under the Environment (Protection) Act, 1986 (Ministry of Environment Forests and Climate Change, 1991). The notification defined the coastal stretches of areas consisting of seas, bays, creeks, rivers, and backwaters, which are influenced by tides up to 500 m from the high tide line (HTL) and the land between the low tide line (LTL) and the HTL as coastal regulation zone and prescribed permissible activities (Ministry of Environment Forests and Climate Change, 1991). The 1991 CRZ Notification classifies the areas into four categories depending on their ecological vulnerability and stage of development:

CRZ I: This category includes the ecologically vulnerable coastal areas. Absolute prohibitions have been prescribed for construction within reach of 500 m of HTL or between LTL and HTL (Ministry of Environment Forests and Climate Change, 1991).

CRZ II: This category includes developed areas that are close to the shoreline. Buildings are only allowed only on specified areas in accordance with the existing local town and country planning regulations, including the existing norms of Floorspace Index (FSI) or Floor Area Ratio (FAR) (Sundar, 2014).

CRZ III: This category includes undisturbed areas that are not designated in CRZ I/II. An area up to 200 m from the HTL is earmarked as No Development Zone (NDZ) and no new constructions are allowed (Ministry of Environment Forests and Climate Change , 1991).

CRZ IV: The category constitutes small islands like Andaman and Nicobar, and Lakshadweep. Subsequently, changes were made to the notification from 1991 to 2009, and all these changes were consolidated through a notification in 2011

(Ministry of Environment Forests and Climate Change, 2011). While retaining the basic categorization of CRZ 1991, it brought certain features (Puthucherril, 2011):

1. New additions were made to the category of CRZ by identifying critically vulnerable coastal areas such as the Sundarbans (Panigrahi & Mohanty, 2012).
2. Time-bound clearance and post-clearance monitoring of projects have been introduced along with enforcement mechanisms.
3. Water areas up to 12 nautical miles in the sea and the entire water area of a tidal water body such as the creek, river, and estuary are included in the CRZ areas, without imposing any restrictions on fishing activities.
4. The notification brings in the idea of “hazard line” without defining it. The mapping and demarcation of the same will be undertaken by the MoEF (Purohit & Markus, 2013).
5. For implementing the notification at the ground level, the responsibility of developing the CZMPs is assigned to the state governments, and this has to be done with the involvement of the local communities (Gupta, 2013).

The 2011 Notification was superseded through CRZ Notification 2019 (Ministry of Environment Forests and Climate Change, 2019). The salient features of the notification include the following:

1. Encouraging tourism infrastructure for public use in coastal areas like shacks, toilet backs, and drinking water facilities on beaches.
2. The procedure for CRZ clearances has been streamlined.
3. Considering the unique characteristics of islands, it is prescribed that CRZ of 20 meters from the HTL on the landward side shall be applicable to islands.
4. The Critically Vulnerable Coastal Areas (CVCA) will be managed by the participation of coastal habitats, including fisher folks (Ministry of Environment Forests and Climate Change, 2019).

It is important to note that for the CRZ notifications to be operational a CZMP needs to be prepared and notified. It is at the stage of preparation of the CZMP public consultations, and the participation of stakeholders is involved. The CZMP is significant in determining the contours of HTDL and LTDL. There has always been a time lag between CRZ Notification and the adoption of the CZMP. The CZMP for the 1991 CRZ was notified only in 1996. Similarly, the CZMP for the 2011 CRZ Notification was adopted only in 2019. Hence, practically speaking, even after the CRZ Notification in 2019, till the time CZMP is modified and adopted, the CZMP of the CRZ Notification of 2011 will hold the field. India's tryst with coastal management did not, however, remain confined to legislative enactments. Judicial pronouncements continue to shape the way in which the state implements coastal regulation and promotes sustainable development. The following section will elaborate on some of the major threads of judicial statements.

Major Judicial Trends

Balancing the Permissible Activities

Judicial statements have clarified the contours of permissible activities in the coastal zone. For example, in *S. Jagannath v. Union of India* (1997), popularly known as the shrimp case, the Supreme Court opposed further conversion of agricultural land into aquaculture farms. It held that the shrimp industries functioning within the coastal regulation zone and within 1000 m from Chilka and Puliket Lakes are liable to compensate the affected persons on the basis of the “polluter pays” principle. The apex court also directed the union government to constitute an authority under Sec 8(3) of the EPA 1986. It was pursuant to this direction that the National Coastal Zone Authority (NCZMA) and State Coastal Zone Authorities (SCZMA) were set up in order to operationalize the CRZ Notification (Purohit & Markus, 2013). In *Union of India v. Chennai Metropolitan Development Authority*, it was held that the prohibition of construction under the coastal regulation laws applies not just to industrial activities but also to residential buildings as well (Union of India v. Chennai Metropolitan Development Authority, 2006). The National Green Tribunal (NGT), while examining the clearance granted to the Vizhinjam International Seaport Ltd, directed its promoters to retain the fisheries harbor near the proposed seaport considering the livelihood of the local fishermen (Wilfred J. Anr v. MOEFCC & Ors, 2016).

Adoption of Environmental Principles

The adoption of international environmental principles has been one of the major strands of environmental jurisprudence in India. In *the Goa Foundation case* (Goa Foundation v. Goa State Coastal Zone Management, 2001), the construction of the “Sunset Dunes” resort at Baga beach was challenged as violating the CRZ Notification 1991. Though the court could not find any violation of CRZ norms, it emphasized the significance of environmental principles. It observed that “there cannot be any doubt that there should be a sustainable development and there should be a (sic) and harmonious co-existence of nature's bounty and mankind's development.” In *Worli Koliwada Nakhwa & Others v. Municipal Corporation of Greater Mumbai & Others* regarding construction of a coastal road on the western coast of Mumbai, the Bombay High Court relied on the precautionary principle and stressed the need for a comprehensive EIA. It is important to mention that though the judicial statements have attempted to incorporate environmental principles, the CRZ Notifications have not incorporated any of the core environmental principles like sustainable development, public trust, and intergenerational equity under its explicit provisions (Puthucherril 2018). However, the 2019 CRZ Notification makes references to the idea of sustainable development.

Institutional Authority

In the landmark case of *ICELA v. Union of India*, the Supreme Court obligated the state governments to create their CZMPs (Indian Council for Enviro-legal Action v. Union of India, 1996). In *Fazal Gafoor*, the applicant challenged the Panchayat order for the demolition of a residential building for the alleged violation of the CRZ norms. The Supreme Court diverted the onus of decision-making to the Coastal Management Authority and held that Panchayat is not the legal body for ordering any demolition (P.A. Fazal Gafoor v. State of Kerala, 2003). Similarly, in *Alexio Arnolfo Pereira*, the petitioner contended that the Directorate of Tourism, State of Goa, has usurped the powers of the Goa Coastal Zone Management Authority (GCZMA) and managed the construction of temporary shacks and huts in Mazorda and Utorda. The court held that the GCZMA is only entitled to permit the erection of purely temporary structures between September and May months in CRZ III subject to compliance with the coastal regulations. However, in this case, the court held that the permission of GCZMA was taken (Alexio Arnolfo Pereira v. State of Goa, 2014).

Maradu Case Impact on Environmental Jurisprudence

The *Maradu* judgment needs to be seen in the larger background of numerous measures and principles articulated by the judiciary in protecting the vulnerable coast of the country. It should be noted that *Maradu* is not the first case where the court has ordered the demolition of constructions in violation of coastal regulations. However, *Maradu* is the first time when demolition of such a massive scale has been undertaken. The judgment highlights the never-ending debate between environmental protection and development pursuits and offers a compelling message for environmental protection. The *Maradu* judgment tries to debunk the traditional judicial bias against the displacement of the upper sections of societies in comparison to the frequent displacement orders against tribals and other marginalized sections of the society. The immediate impact of the *Maradu* case can be seen in the case of *Kapico Resorts*. Before the start of demolition of apartment complexes in *Maradu*, the Supreme Court upheld the demolition order passed by the High Court of Kerala for the razing of a luxury resort in the Vembanad Lake built in violation of CRZ Norms (*Kapico Kerala Resorts Pvt. Ltd v. State of Kerala*, 2020) While the judgment provided a strong precedent for the enforcement of environmental protection laws, the rationale employed by the court in *Maradu* has left open some fundamental questions.

The Supreme Court in *Maradu* reasoned that the 1991 CRZ Notification is applicable to the impugned constructions. This brought the impugned constructions in CRZ III, wherein the area of 200 meters from the HTL is considered an NDZ. It is relevant to acknowledge that a CRZ Notification can only be operationalized using a CZMP. In reality, the CZMP is approved only many years after the CRZ Notification. For instance, even though the First CRZ Notification was issued in 1991, its CZMP was approved only in 1996 (Geevan, 2021) (Kapoor, 2017). Thereafter, even though

the second CRZ Notification came in 2011, its CZMP came to be approved only in February 2019 (Geevan, 2021).

In *Maradu*, it is a fact that constructions happened during the currency of the 1991 CRZ Notification along with its CZMP (approved in 1996). Both came into being when *Maradu* was a Panchayat, squarely making it a CRZ III area. It is to be noted that *Maradu* was converted into a municipality in November 2010, and this is why the draft CZMP to the 2011 CRZ Notification marks it as a CRZ II area. However, it was only in February 2019 that the CZMP to the 2011 CRZ Notification recognizing *Maradu* as falling under CRZ II came to be approved. This meant that before the Supreme Court judgment was pronounced on May 8, 2019, the impugned constructions became part of CRZ II. It also meant that the buildings in violation of CRZ III might not violate CRZ II. The Supreme Court should have taken note of this factual history and addressed the question as to whether, in respect of the impugned buildings that were constructed under the earlier notification, the rules applicable should be the ones that are in force at the date of judgment or on the dates of construction.

This case thus raises certain questions about the retrospectivity of CRZ regulations. The Supreme Court in *Goan Real Estate and Construction Ltd. and Ors. v. Union of India (UOI)* went on to say that the landmark decision in *Indian Council for Enviro-Legal Action Action* (Indian Council for Enviro-legal Action v. Union of India, 1996) relating to CRZ regulations is only prospective. It has also been held in many decisions that environmental regulations are not retrospective (Narmada Bachao Andolan v. Union of India, 2000) (Rajendra Shankar Shukla v. State of Chhattisgarh, 2015) (Common Cause v. Union of India, 2017). In the instant case, the 2019 CZMP marks *Maradu* as CRZ II, wherein restricted constructions are allowed on the landward side of existing authorized structures. However, the protection of the 2019 CZMP is not available for these constructions because of the prospective nature of environmental regulations. Even though environmental laws are characterized by non-retrospectivity, in the instant case it can create a complex precedent. However, overlooking the fact that the impugned constructions on the date of judgment fall under CRZ II the Supreme Court denied a beneficial interpretation of the law. Theoretically, it is even possible that constructions may come up in consonance with CRZ II norms on the same site where the apartment complexes were demolished (Nedumpara, 2021).

In an interesting twist, the Supreme Court of India asked the Kerala government to furnish the list of all CRZ violations in the state (*Kerala State Coastal Zone Management Authority v. The State of Kerala Maradu Municipality*, 2019). Pursuant to this order, the Government of Kerala created Coastal District Committees in its 10 coastal districts for ascertaining the number of buildings violating the CRZ norms. In October 2020, the Government of Kerala filed an affidavit in the Supreme Court admitting the total number of CRZ violations in Kerala to be 27,765 (Narayanan, 2020). It will be both cathartic and cataclysmic if the court applies the same principle of non-retrospectivity to all the CRZ violations in the state (Kumar, 2019). If it does, then *Maradu* will become a *T N Godavarman* (by which the Supreme Court of India took over the management of the forests of the country) (Rosencranz & Lélé, 2008)

(Chowdhury, 2014). The apex court also went on to appoint a judicial commission for compensating the apartment owners who lost their homes and asked the state government to pay each of the apartment owners an interim compensation of Rs.25,00,000/- each, and this amount was to be recovered from the builders (Kerala State Coastal Zone Management Authority v. The State of Kerala Maradu Municipality, 2019). It is also important to note that the second leg of the *Maradu* case is still continuing in the form of a *suo moto* case before the Southern Bench of the National Green Tribunal. In addition, a crime branch investigation of the builders and officials is underway (SIT Opens Criminal Investigation Against Builders, 2019). It is also argued that the fact that the apartment complexes were demolished without undertaking an environmental impact assessment on the possible environmental impact on the fragile wetlands, waste debris, and air pollution challenges the very object, legitimacy, and efficacy of the demolition (Kurien, 2019).

The case highlights the lack of coordination between administrative bodies, courts, and environmental protection agencies. The fact that the Grama Panchayat permitted the construction and an injunction against the stay order was passed by the High Court is pertinent here. Even though the constructions were allowed to be continued by the High Court, the brunt of the judgment was borne by the bona fide purchasers. Thus while celebrating the *Maradu* judgment, it is also important to keep in mind the need for consistent and coherent decision-making.

Conclusion

The vulnerability of India's vast coastal area is well documented. Categorizing coastal zones and prescribing the list of prohibited and permissible activities through CRZ regulations, the government has attempted to protect the country's coastal zones. The legislative initiatives were supplemented and complemented by an active judiciary that has attempted to balance the economic and environmental imperatives. By ordering the demolition of high-rise apartment complexes in *Maradu*, the court is believed to have set a stickler standard for environmental adjudication in India. However, the detailed analysis of facts and the law involved in the case raises staid questions about the retrospective application of environmental regulations and especially with regard to the narrative on environmental rule of law as laid down by the Supreme Court in *Hanuman Laxman Aroskar and Ors. v. Union of India*. It will be interesting to see how the Supreme Court of India reacts to the cases of CRZ violations in the state provided by the Government of Kerala as it raises the possibility for *Maradu* tracing the trajectory of *T N Godavarman* and its attendant judicial overreach. This suggests that, while celebrating the *Maradu* judgment, it is important to consider the need for coordinated decision-making among various environmental agencies.

Abstract

With many variants being discovered every day, COVID-19 pandemic is still raging around the globe. It has been a traumatic experience not only for humans but also for pets and homeless animals, the closest and the most dependent types of animals living in the vicinity of people. Many pets were abandoned and mistreated due to various reasons, and homeless animals continuously struggled to find food and water during the pandemic lockdown and other restrictions. Mistreatment and negligence toward pets and homeless animals are considered as crimes since they are protected within the national legislative framework in most of the countries. However, compared to the scope and rapid development on the legal measures for pets and homeless animals in developed countries, the South Asian nations are struggling to enforce the existing frameworks and adapt measures against new challenges such as the COVID-19 pandemic. This research intends to explore the welfare issues encountered by pets and homeless animals in the South Asian region during the COVID-19 pandemic and the legal protection

D. Seethawaka (✉)

granted to them against such issues. Furthermore, it will investigate the mitigation, preparedness, and response steps that must be adapted in order to resolve any existing gaps and ambiguities by comparing such measures which are implemented in developed countries, with variables such as economic, social, and development progresses in mind. The suitable solutions will then be analyzed as to their applicability to the South Asian countries, and further recommendations for the future will be suggested.

Pets and homeless animals · Animal welfare · Animal cruelty · Pet grief · COVID-19 pandemic

Introduction

The COVID-19 pandemic has been the most unanticipated global emergency in the twenty-first century causing more than six million deaths by March 2022 (World Health Organization, 2022). Humans are not the only victims of the pandemic, since the living conditions of animals all around the world were subject to various welfare, cruelty, and socioeconomic challenges (Grant, 2020, para 2). Almost every type of animal including wild, farm, research, companion, and livestock suffered because of the pandemic. For instance, due to lack of visitors and guards in the national parks and reservoirs, the wild animals in Asia and Africa were threatened with poaching (Grant, 2020). The fur animals were culled in millions after detecting SARS-CoV-2 outbreaks in farms in countries such as the Netherlands, Denmark, the USA, etc. (Grant, 2020). Since people refrained from meat consumption, many livestock farms which got overcrowded with poultry and meat animals opted to kill them in the cruelest methods (Grant, 2020). The animals used in research facilities had to suffer because the COVID-19 vaccine research were carried out on them (Grant, 2020). Pets were abandoned due to the fear of being exposed to the virus and other economic difficulties (Grant, 2020).

The South Asian nations also experienced similar scenarios relating to the well-being of animals during the pandemic irrespective of whether they are pets, strays, captivated animals, livestock, laboratory animals, or wildlife (Choudhary et al., 2020). Even though there are rules and regulations in South Asian countries to ensure that animals do not undergo physical or emotional pain and suffering, the COVID-19 pandemic proved that the reality is different from the legislature. Therefore, it is necessary to conduct research to clearly identify and analyze the imminent threats and available legal protection to animals during a pandemic for several reasons.

One such reason is that it is not certain when the COVID-19 pandemic would be completely eradicated (Charumilind et al., 2022). The citizens of South Asian nations have had a close association with animals and are compassionate toward their well-being. However, during the pandemic it was observed that when people

are confronted with unforeseen difficulties, they tend to make the selection based on their priorities and convenience. Therefore, it must be ensured that pandemic restrictions are not provided as justifications or excuses for not fulfilling the duties as compassionate human beings.

At the same time, many of the ongoing researches predict that in the future, zoonotic disease outbreaks which would be as dangerous as the COVID-19 can occur. One cause of such outbreaks is the illegal wildlife trade which is also considered as the source of SARS-CoV-2 (United Nations Office on Drugs and Crimes, n.d., p 2). It is also reported that previous zoonotic disease outbreaks, such as avian influenza and swine flu, have originated from livestock operations (Grant, 2020). Therefore, it is essential that the South Asian countries are well-prepared for any similar pandemic that might occur in the future and ensure that the safety and well-being of animals are not compromised.

Developed nations are constantly encouraged to find fast-track solutions for the protection of animals, particularly because if cruelties against animals are not prevented in the initial stages, they might create bigger issues in the long term. Similarly, developing nations must also focus on the broad perspective and thereby address the concerns without further delay. Even though there are ample research articles that discuss the mistreatment toward animals during the pandemic in the South Asian context, there is a research gap relating to the analysis of domestic legal protection granted to animals and measures and mechanisms that can be adapted in order to ensure their safety in any similar future occurrences.

However, due to time and word limitations and other restrictions, this chapter only focuses on caring for pets and homeless animals during a pandemic. Thereby, in the context of this chapter, “pets” are defined as the domesticated animals which are kept as companions, and “homeless animals” are those who were once companion animals, but then abandoned by their owners and are now considered as stray animals. One of the main reasons for selecting these two types is because they are completely dependent on human beings and cannot survive unless they are provided sufficient food, water, and care (Waxman, 2021, para 2). Hence, companion and domesticated animals were one of the most vulnerable groups during the pandemic (Applebaum et al., 2020; Berry, 2020).

This research explores how pets and homeless animals can be protected during a pandemic, with specific reference to South Asia, and will be carried out using the black letter approach of research. The research question is how the South Asian nations can develop their legislative frameworks and include mitigation, preparedness, and response measures to safeguard the pets and homeless animals during a pandemic.

The chapter first investigates the welfare concerns of pets and homeless animals which arose due to the COVID-19 pandemic, with examples limited to India and Sri Lanka. These examples would be analyzed in the context of the existing legislative frameworks of the selected nations, i.e., the Prevention of Cruelty to Animals Act 1960 of India and the Prevention of Cruelty to Animals Ordinance of 1907 in Sri Lanka, which would be helpful to identify the gaps and ambiguities. In order to suggest the improvements which can be introduced to South Asia, the

chapter will refer to applicable legal provisions and other mechanisms from developed nations which can be used to inspire the South Asian nations. Accordingly, mitigation, preparedness, and responsive measures on safeguarding pets and homeless animals during a pandemic will be considered in recommendations.

Welfare Concerns of Pets and Homeless Animals During the COVID-19 Pandemic

This section discusses the pandemic-induced concerns which affected the welfare of pets and homeless animals in India and Sri Lanka, followed by analyzing the legal provisions and thereby attempting to identify the legal gaps and ambiguities. Prior to the discussion on specific issues and pertinent legal framework, it is necessary to consider the constitutional provisions which protect pets and homeless animals in the selected nations. The Fundamental Duties of the citizens of India enshrined in Article 51A (Part IV-A) of the Constitution of India provides that “It shall be the duty of every citizen in India: . . .(g) to protect and improve the natural environment including forests, lakes, rivers and wildlife, and to have compassion for living creatures . . .” (Constitution of India, 1950). Hence, it is the duty of every Indian citizen to ensure that any creature including pets and homeless animals is not subject to suffering and pain.

The landmark judgment given by the Supreme Court of India in the case of *Animal Welfare Board of India v. A. Nagaraja & Ors.* provides several significant interpretations on constitutional provisions which validate the safety of animals in India. The term “compassion for all living creatures” as per Article 51A of the Constitution was interpreted to include concern for suffering and well-being of animals. Furthermore, it declared that Fundamental Right in Article 21 on right to life includes the right to life of animals. Accordingly, any animal in India is guaranteed constitutional protection against any form of cruelty, suffering, and mistreatment which would affect its honor and dignity by any person under any circumstance. This interpretation is essential to determine that pets and homeless animals in India not only have a right to life but also to lead a life with honor and dignity.

However, the Constitution of Sri Lanka does not provide for such definite provisions on animal protection, and hence, it can be construed that the Constitution of Sri Lanka, the supreme legal entity of the nation, fails to establish animal protection within its provisions.

Next step is to investigate specific concerns which affected the welfare of pets and homeless animals in India and Sri Lanka during the pandemic, thereby amounting to actions of animal cruelty. Animal cruelty can be considered as purposeful actions or failure to act which causes pain and suffering for the pets or homeless animals (Hussain, 2021, para 2). This chapter considers three main methods of animal cruelty, namely, inflicting harm to animals, neglecting the duties toward animals, and abandoning animals. These were selected based on the availability of actual

incidents suffered by the pets and homeless animals during the pandemic in the context of India and Sri Lanka.

Inflicting Harm to Pets and Strays by Committing an Act

A person can inflict harm to a pet or a stray by kicking, burning, stabbing, beating, shooting, raping, etc. (Animal Welfare Institute, n.d., para 1). The tendency of inflicting harm to animals is considered as a well-established early indicator of future assault, serial killing, rape, and partner and child abuse (Futterman, 2021; Hodges, 2008). Research indicate that 25% of aggressive prisoners, 45% of school shooters, and 21% of serial killers had committed animal abuse and cruelty as children (Futterman, 2021). Therefore, inflicting harm to pets and strays cannot be taken lightly.

There were many incidents of pets and homeless animals being tortured in India during the pandemic. Experts have warned that animal abuse cases in India have increased at an alarming rate since April 2020 lockdown (Sood, 2021; Behl, 2020). Some of these incidents were reported, some were disregarded even though they were duly reported, and many were not even reported (Sood, 2021). In 2020, 886 cases were registered only from Mumbai on animal abuse, and in some days daily count spiked up to 8 cases (Sood, 2021).

A few instances include a female dog in Nagpur being stabbed on the forehead using a sharp object (Behl, 2020). There was also a dog whose eyes were brutally pulled out using a sharp object in Naik Nagar (Behl, 2020). There were several reports on raping and killing of female dogs (Sood, 2021). One accused even argued that female dogs did not object since he was feeding them, and hence it does not amount to a crime (OpIndia, 2021, para 9). There were also reports on torturing animals to increase the followers in social media (Singh, 2020a).

There are several contributory factors to the increase in such incidents in India. Police and welfare activists share the view that some people consider animal abuse as a sport which has intensified during the pandemic since people were stuck indoors with their pets or due to lack of people in roads and common spaces (Sood, 2021). Hence, it can be considered that pandemic lockdowns triggered such actions and the threat still prevails. The frustration of losing jobs and inflation are also considered as reasons for the alarming increase in animal abuse during 2021, compared to 2018 and 2019 (Sood, 2021; Behl, 2020). Welfare activists and experts also argue that lenient legal provisions, lack of public awareness, and insensitivity toward animals also caused animal abuse (Sood, 2021).

The existing legal framework on this regard in India is found in the Prevention of Cruelty to Animals Act 1960 (hereinafter PCA Act) which provides comprehensive guidelines to protect pets and homeless animals against infliction of any harm by any person. Section 2(a) of the Act defines an animal as any living creature other than a human being. This means any pet or homeless animal falls within the definition of an animal in the context of this Act.

Section 3 of PCA Act establishes a duty on every person who is in charge or care of animals to ensure the well-being and to prevent inflicting unnecessary pain or suffering on the animal. Accordingly, the owner or a custodian of a pet is entitled to care for an animal. Also, if any person has inflicted any harm to an animal by committing an act which is specified in section 11(1)(a) including beating, kicking, torturing, or any other act of causing unnecessary pain or suffering to the animal, it amounts to an offence of treating animals cruelly.

Hence, all the acts which were discussed in the aforementioned examples are crimes according to the PCA Act, which protects all pets and strays against any person including the owner and custodian. However, the fine which is specified for such an offence is a maximum of 100 Indian rupees or 3-month imprisonment. This clarifies as to the reason why people are not scared to inflict harm to animals and not hesitant to repeat crimes.

Furthermore, as per Sections 428 and 429 of the Indian Penal Code (hereinafter IPC), killing or maiming any animal is considered as a punishable offence. If the value of any animal is more than 50 rupees, the punishment includes a fine, 5-year imprisonment, or both. If the value is more than 10 rupees, then 2-year imprisonment, a fine, or both. Thereby, pets and homeless animals are protected by Sections 428 and 429 of the IPC.

Compared to India, hardly any incidents were reported on cruel treatment to pets or homeless animals in Sri Lanka. However, it does not completely mitigate the fact that none of the pets and homeless animals have suffered any abuse by frustrated people during the pandemic. Therefore, it is appropriate to consider the probability of such actions taking place in Sri Lanka and thereby take preventive actions. The applicable legal instrument is the Prevention of Cruelty to Animals Ordinance, No.13 of 1907 (hereinafter PCAO).

Sections 2(1)(a) and (b) of the PCAO state that any person who cruelly beats, ill-treats, abuses, or tortures any animal or does any act or omission which causes unnecessary pain or suffering to any animal is punishable with a fine of 100 rupees, 3-month imprisonment, or both. Killing any animal in an unnecessarily cruel manner is also prohibited by section 4 of the PCAO. However, the concern is that the Ordinance is not applicable to homeless animals in Sri Lanka, because as per section 14 the definition of an “animal” only includes domestic, captured, and animals in captivity. Therefore, homeless animals in Sri Lanka are not protected within any legislative framework against any cruelty.

Inflicting Harm to Pets and Strays by Omitting an Act

In this regard, omitting an act means during the pandemic a person has failed to provide food, water, shelter, medical care, and adequate exercises to the animals they are in charge of and thereby caused pain for pets and homeless animals. The instances of such infliction of harm were common in both India and Sri Lanka. When lockdown and travel restrictions were announced in countries, there was confusion regarding interstate distribution of animal food and accessing veterinary

care facilities (Tiwari, 2020). Furthermore, due to the fear of dogs contracting the virus, many owners avoided outdoor activities, which caused stress and hyperactivity in pets (Palisetty, 2021). If a pet dog is confined to a cage or a limited space, such an animal requires daily exercises and other physical activities, which were unavailable during the pandemic (Palisetty, 2021).

Also, owners and homeless dog feeders were struggling to provide food for the animals they care for due to staggering financial conditions (Prasad, 2021, para 1). The homeless animals were among the most affected during the pandemic because they were unable to find food and water (Tissaaratchy & Fernando, 2021; Rozais, 2020; Tiwari, 2020; Choudhary et al., 2020). There were also reports of negligent drivers who would drive at a higher speed due to lack of traffic and did not bother to help or call for help if an animal met with an accident (Rana, 2021). Hence, the sick and injured strays were left to die without medical treatment (Rana, 2021; Bhatnager, 2020). There were also incidents where individuals and Resident's Welfare Association (RWAs) in India had opposed feeding stray dogs and prevented pets from using common amenities in communities (Kadidal, 2020, para 3).

If any owner has deliberately or negligently allowed any pet or homeless animal to suffer by failing to provide sufficient food and water, shelter, and reasonable exercises, as per Sections 3 and 11(1)(f), (g), and (h) of the PCA Act of India, he has committed an offence and is liable for a fine of 100 rupees, 3-month imprisonment, or both. In Sri Lanka, such an offence is punishable under Sect. 2(1)(b) of the PCAO by failing to act and section 3 of the PCAO if any animal is found suffering due to starvation or any other ill-treatment. Applicable punishment is 100 rupees fine, 3-month imprisonment, or both. However, as it was already discussed, this provision in PCAO is only available for pets.

Abandoning of Pets

A major concern during the pandemic which was unanimously confronted by all nations is abandoning of pets (Wollaston, 2021; Davies, 2021; Prasad, 2021; Morris, 2021; Grunebaum, 2020). It is now observed that pets have been abandoned during the initial stages of the pandemic, as well as in the recent stages of the pandemic. Reports suggest that many pets were abandoned during the first and second waves of the pandemic due to the fear that they might be a vector of transmission (Das, 2021, para 6; Sharma, 2020).

Yet another reason for abandoning pets is loss of employment, which causes the owners to either give up their pets due to economic difficulties or return to their rural hometowns leaving the pets in the cities (Mavad, 2021; Singh, 2020b). There were also incidents when sick pets were abandoned when the owners could not get timely medical treatment (Das, 2021) and owners dying from the virus which left the pets alone and unattended of which only some were rescued (Mavad, 2021; Kalra, 2021).

Recent reports further indicate that people are abandoning pets that were adopted during the lockdown (Das, 2021). Pandemic pet adoption became a resolution to help people who were emotionally distressed due to lockdown restrictions and social

distancing (Das, 2021, para 1; Maneckshaw, 2020). This resulted in a rapid increase for pet adoption which was considered as a positive approach (Das, 2021, para 1; Maneckshaw, 2020). However, when the lockdown restrictions were slowly removed and people had to return to work, they opted to either return their pandemic pets to shelters or simply abandon them in the streets (Kalra, 2021). Some other reasons for abandoning pets include lack of knowledge on dietary and medical treatment, heavy expenses to care for pets, and lack of food items.

Abandoned family pets cannot survive in the streets because they do not have the skills to fend for themselves and often struggle due to unavailability of food, water, and medical care, navigating road traffic, conflicts with feral dogs, harassment from humans, etc. (Rozais, 2020). Furthermore, they undergo emotional trauma and anxiety due to separation from their owners (Rozais, 2020). In this process, if they try to seek out human company from strangers, people might use cruel methods to chase them, which might inflict injuries to the animals. Hence, many pets which were abandoned died of starvation, dehydration, fatal injuries, or illnesses (Rozais, 2020).

If abandoned pets are not rescued and somehow manage to survive in the streets, they become a part of the strays. It is reported that nearly 79.9 million homeless dogs and cats are found in India (The Economic Times, 2021). Increasing population of such homeless animals can intensify the spread of various diseases including rabies. The state is responsible for conducting animal birth control (hereinafter ABC) programs and vaccination programs against rabies which would require considerable resources. Many nongovernmental organizations also organize ABC and vaccination programs due to the rising number of homeless animals. However, most of such programs were temporarily stopped due to the pandemic further increasing the population of homeless animals (American pets alive, 2020).

Abandoning pets is forbidden by Sections 3 and 11(1)(i) of the PCA of India. Section 11(1)(i) states that no person can abandon any animal causing it to suffer by starvation or thirst without a reasonable cause. The penalty is the same as was mentioned in other sections. Homeless animals are further protected from killing, dislocation, or relocation as per Animal Birth Control (Dogs) Rules, 2001. Sections 428 and 429 of the IPC prescribe severe punishment to any person who dislocates, abducts, or commits an act of cruelty toward pets or community dogs (Sood, 2021). However, a survey revealed that among nine countries, India recorded the highest pet abandonment with a score of 2.4 out of 10 (Das, 2021).

In Sri Lanka, Section 7 of the PCAO prohibits any owner from abandoning any diseased or disabled animal in any street without reasonable excuse and imposes a fine of 100 rupees or 3-month imprisonment. The weakness of this provision is that it only protects sick or disabled pets to some extent and exposes healthy pets who were abandoned due to various reasons during the pandemic. This reaffirms the necessity of revising 115-year-old prevalent laws in Sri Lanka with timely provisions and reasonable penalties.

After the comprehensive discussion on the specific circumstances which caused pain and suffering to pets and homeless animals in India and Sri Lanka during the pandemic, the causes which instigated such incidents and the scope of legal protection granted to such animals, it is necessary to investigate what recommendations can be introduced to ensure humane treatment and proper care toward such animals.

Recommendations

The recommendations are discussed in three categories, namely, mitigation, preparedness, and response steps with appropriate suggestions from developed nations. It was also observed that India had executed several significant measures to safeguard pets and strays during COVID-19 pandemic. These will also be considered as appropriate suggestions for other South Asian countries given the common economic, political, and social grounds.

Mitigation Steps to Protect Pets and Homeless Animals During a Pandemic

In disaster management, mitigation is the process which reduces or eliminates the impacts of a disaster on people and property (Newbedford, n.d.). In relation to this study, it stands for eliminating and reducing the risks encountered by pets and homeless animals by people due to pandemic-induced reasons. The most appropriate method which can eliminate and reduce such risks to any animal including the pets and homeless animals is implementing strong and timely animal protection and welfare legislation.

Constitutionalizing animals is the highest level of protection that can be granted to any animal in a country against any cruelty by any person (Eisen, 2018). Constitutional protection for animals mandates all government authorities to ensure that animal welfare is duly recognized within the national legal and value systems and empowers further political, institutional, and legislative developments (Bolliger, 2007). Furthermore, it guarantees that other basic rights and privileges of a person including the freedom to follow a religion, choose a profession, and engage in scientific and artistic endeavors do not have priority over suffering of animals (Bolliger, 2007).

Several developed nations including Switzerland, Germany, Luxembourg, and Austria have enacted constitutional provisions to protect the interests of animals (Eisen, 2018). India is the only nation in South Asia which has duly secured animal protection in the Constitution. If a multiethnic, multireligious, and diverse nation such as India can safeguard animals in the constitution, other South Asian nations which have not enshrined animal protection in their respective constitutions must also be encouraged to give due recognition to animals in the constitution.

Uplifting national legislative protection for animals is also essential. It was clearly evident that punishments specified in both PCA in India and PCAO in Sri Lanka are not adequate. The proposed Animal Welfare Act in Sri Lanka provides penalties of a fine of 25,000 rupees and a 2-year imprisonment for any act which can cause unnecessary pain to an animal (Animal Welfare Bill, 2022, Sec. 3(2)). This is a significant development compared to the prevalent provisions in the PCAO.

Similarly, all South Asian nations must ensure that their national legislative framework to protect animals including pets and homeless animals are duly updated to address any form of cruelty which can cause unnecessary pain and suffering to any animals. Furthermore, they must prescribe reasonable penalties which can instigate fear in the minds of people who are likely to cause harm to animals and prevent them from repeating such acts.

Duly enforcing prevalent laws is also important in mitigation, which can be carried out by personnel who are well-trained and competent in identifying animal cruelties and taking necessary actions to prevent such cruelties. The officers in police stations must be encouraged to duly report and carry out investigations when complaints on animal cruelties are made by citizens (Sood, 2021). There are instances in South Asian nations where police officers disregard animal cruelties stating that there are no adequate laws to take actions, and they cannot protect animals when they are occupied with other work. Therefore, it is important to organize workshops, training programs, and conferences which can educate all state personnel who are empowered to take actions against the people who hurt animals.

Yet another group which requires education on the legal provisions concerning animal protection is the general public. Even though there is adequate protection and stringent penalties, if the public is not aware of the law, then there is no guarantee that people will fulfil their responsibilities as compassionate human beings during a frustrating time period. It is a common observation in South Asia that people specially living in rural areas do not know that their certain actions or ignorance can amount to an offence punishable in law. Therefore, mass media platforms such as television, radio, newspaper, social media, etc. can be used to educate the general public, and sufficient funding must be allocated to such awareness programs.

It is also essential to appoint a group of dedicated animal welfare policy advisors to collect data and feedback, analyze emergency situations, conduct research, execute proper action plans and law, and make appropriate recommendations during the times of disasters including an ongoing pandemic (Department of Primary Industries and Regional development, 2018). Since the COVID-19 pandemic was an unforeseen emergency, private organizations and individuals took undue advantage of the panic and fear among people which often caused despair to pets and homeless animals (Mason, 2021; Woodyard, 2020). The expert policy advisors can prevent such situations and take precautions to address them. These are some of the steps that can be useful to mitigate causing harm to pets and homeless animals during the pandemic.

Preparedness to Protect Pets and Homeless Animals During a Pandemic

Disaster preparedness includes a set of actions commenced primarily by governments, authorities, organizations, communities, or individuals to better respond and cope with the immediate aftermath of a disaster (European Commission, [n.d.](#)). The main objective of initiating such preparation methods is to minimize loss of lives, in this instance the lives of pets and homeless animals. Hence, this relates to providing adequate food, medical care, shelter, and other essentials to pets and homeless animals which are required to maintain their physical and mental well-being during the pandemic.

Lack of pet food supplies was also identified as a cause of pet abandoning and starvation of homeless animals, and nations sought different solutions. For instance, in India the Ministry of Home Affairs declared pet food as an “essential item” and exempted interstate supply chains of animal feed and fodder from lockdown (Tiwari, [2020](#)). In the UK the pet owners were encouraged to maintain hygiene and healthy diets and engage in socially distanced exercises and indoor activities to the pets (Bakir, [2020](#)). In Turkey, the interior ministry ordered all local councils to provide food and water to all other places where animals are found (Karlidag, [2020](#)). Some organizations established food banks which helped pet owners to get free pet food (Four Paws International, [2020b](#)). Other nations can also be inspired to follow such methods and ensure that lack of pet food will not be a hindrance during the pandemic.

Creating animal welfare charities is yet another method which can assist in providing monetary aid to pet owners facing economic difficulties and animal welfare charitable organizations struggling with lack of donations. In the UK, animal charities started a petition to request the government to include animal charities in emergency funding, and accordingly, many welfare charities were able to take advantage of the Coronavirus Job Retention Scheme (Petitions, [2020](#)). The government also took the initiatives to raise funds and launched several emergency grant schemes (Petitions, [2020](#)).

Not restricting pet travel during the pandemic is also essential, and several preparedness steps can be considered in this regard. Creating transport methods for owners to carry their pets, establishing emergency transport methods for sick pets or homeless animals, providing special permits across state borders for owners to get medical treatment for their pets, and arranging mobile pet care and veterinary services are some of the recommendations (Animal Emergency & Referral Center of Minnesota, [n.d.](#)). It is recommended that necessary permits and licenses are prepared for such situations. Instead of onsite veterinary care, in the USA and France, veterinarians were allowed to practice telemedicine (MSD Animal Health, [n.d.](#)). Furthermore, US veterinarians received regular guidance from organizations such as the American Veterinary Medical Association on how to operate during a

crisis (Vincent et al., 2020). These initiatives could be useful to South Asian nations given the safety precautions, health guidelines, and resource limitations.

The government can also establish state transport services for animals or duly regulate private companies who would engage in pet transport services. It is mandatory that they are duly registered companies with trained staff to handle animals who would be stressed due to separation anxiety from owners or bad health (Mason, 2021). It was also observed that many airlines either restricted or charged unusually high charges for pet flights during the pandemic causing pet owners to abandon their pets (Mason, 2021; Woodyard, 2020). Hence, it is necessary to pre-plan how the charges will be regulated in all pet transport facilities which is the responsibility of the government.

In some countries the owners were encouraged to prepare a pet action plan, which would be helpful in caring for the pet if the owner becomes sick or hospitalized or passes away (Chaves, 2020; SPCA, n.d.). The pet action plan would include a person to take care of the pet in an emergency, provide adequate food stock, vaccine records, special care or medical necessities, and the pet would be collared with an ID tag (Chaves, 2020). This would be helpful in rescue operations and save resources and time. The veterinary officers and media campaigns can promote such initiatives in South Asian nations.

Despite mitigating and preparedness efforts, there is the possibility that people would tend to mistreat animals. Therefore, having fully equipped animal shelters to house abandoned animals and continuing animal birth control and vaccination programs also amount to preparedness steps. Due to lack of funding, shelters faced difficulties in finding manpower to carry out day-to-day chores. In such situations, they can encourage people to volunteer in shelters while adhering to safety protocols, and such volunteers can be provided with necessary travel permits during lockdowns. However, precautions must be taken to ensure that such permits would not be misused.

The shelters should not only prepare to house the abandoned animals but also ensure that adopted animals will not be returned. For this purpose, pandemic preparedness plans were initiated in France which encouraged the shelters to take all steps to inform the responsibility that lies with adopting or fostering a pet (Lerat et al., 2021). Similarly, dog breeders and sellers must ensure that they inform all the necessary care needed for the animals they sell, so that the owners can respond to emergency situations and challenges of raising a pet during an ongoing pandemic.

These preparedness steps show that the government, state and non-state organizations, and individuals are equally responsible in taking necessary steps to protect pets and homeless animals during a pandemic. However, it is difficult to enforce major decisions and carry out such comprehensive rescue and protection operations when animal welfare is categorized with another Ministry, as the general practice followed in South Asian nations. Therefore, the existing governments must pay attention to form a separate ministry for animal welfare which only specializes in decision-making relating to animal welfare and protection.

Response Steps to Protect Pets and Homeless Animals During a Pandemic

Response in disaster management is the assistance and intervention steps taken during or immediately after an emergency and focuses on saving lives and protecting community assets usually measured in hours, days, or weeks (Resilient Community Organisations, n.d.). In this instance, response steps amount to those actions which can be taken immediately to address certain concerns which would threaten the well-being of pets and homeless animals during the pandemic.

One of the immediate aftermaths which harmed pets and homeless animals is pandemic-induced stress and frustration among the owners, custodians, and other people. This can be avoided by organizing online counselling sessions to help pet owners and other people to manage stress and frustration and not to engage in any activities that might cause harm to animals. Furthermore, mass media can also be a helpful medium to reach and promote public awareness on the necessity of caring for animals who depend on people (Hooper et al., 2021).

It is important to navigate such media campaigns to promote accurate information that would help animals during the pandemic. Posters, posts, and advertisements can be circulated in social media and communities (Onlinefirstaid.com, 2020). Other than creating awareness, mass media can be a platform where experts and influential personnel can encourage people to care for animals without neglecting their duties. For instance, in the UK several charities and experts joined forces to offer advice and guidance and correct conflicting and misleading information during the pandemic (Onlinefirstaid.com, 2020). Such activities can be helpful and easily adopted in South Asian nations.

Yet another significant response step which was highly beneficial for the homeless dogs in India was the New Delhi High Court judgment in the case of *Dr. Maya D. Chablani v. Radha Mittal and Others* which declared that stray dogs have the right to food and the citizens have the right to feed while ensuring that such feeding does not cause nuisance or harassment. This allowed individual and welfare organizations to feed homeless dogs during pandemic restrictions and help the animals to survive. Such landmark judgments can influence other nations on the importance and extent to which animals can be protected.

In response to the pandemic, the government of India ensured that veterinary services continue during the pandemic, and hence they were declared as essential services (Dhingra, 2020). In the state of Minnesota, US veterinary clinics were categorized as “essential businesses” provided that services should be given to urgent and emergency cases (Animal Emergency & Referral Center of Minnesota, n.d.). It was already discussed how animal feed and fodder were also categorized as “essential items” which also amounts to a response step.

It is also necessary to encourage people to report any circumstances of mistreating, neglecting, and causing domestic violence on pets and homeless animals (Four Paws International, 2020a). Since pets and homeless animals are among the most vulnerable animals during the pandemic, the people must safeguard such animals and be empathetic toward their pain and suffering. The animals are unable

to communicate the mistreatments they face, and hence people can be alert to the sudden changes in the behaviors of animals in their vicinity. These are some of the recommendations which can protect pets and homeless animals during the pandemic.

Conclusion

It is evident that pets and homeless animals were subject to immense pain and suffering during the COVID-19 pandemic despite having a substantial scope of legal protection to them. Even though this study did not refer to examples from other South Asian nations, they also faced similar situations. Mahatma Gandhi has stated that “the GREATNESS of a nation can be judged by the way its animals are treated” (Richards, 2014). The COVID-19 pandemic shows the need of treating all living beings with care and kindness, and instilling compassion toward pets and homeless animals can be the starting point for treating all animals with empathy. Hence, it is necessary that South Asian nations implement adequate legal, policy-related, and other measures to safeguard pets and homeless animals during pandemics. However, given the developing status of South Asian nations, it would be a challenge to find necessary resources to facilitate the recommendations. The beginning of this process may seem rather multifaceted, but the long-term outcomes would prove to be beneficial specially, considering the vulnerability of the region for future pandemics and other disasters.

Abstract

This chapter is both a theoretical and empirical discourse on the responsiveness of the bureaucratic norms of governmental response systems in the aftermath of disasters. It starts by discussing the contemporary context, i.e., the “Age of the New Normal” where unexpected catastrophic disasters increase in frequency and become more intensified, also seen to become an everyday staple of life that mankind must learn to deal with. It then argues that to become responsive and be able to restore normalcy immediately after a disaster has struck, bureaucracies must innovate. The challenge becomes complicated, however, when the bureaucracy itself becomes a victim. The chapter summarizes existing knowledge based on current literature on the challenges and problems that the “Age of the New Normal” pose to Public Administration and how the latter respond to them. Second, it discusses how the bureaucracy, idealized by Weber, serves either as facilitating or hindering factor during disaster/crisis situations. Empirical

evidence is provided by showcasing four government agencies that prepared for the onslaught of Super Typhoon Yolanda/Haiyan on November 8, 2013, in Tacloban City, Philippines. Lastly, the chapter presents public service continuity planning as a tool that government agencies could use to provide continuous service in the aftermath of disasters.

Introduction: The Challenges to Governments in the “Age of the New Normal”

“The abnormal is now the new normal,” is how UN Secretary-General Ban Ki-moon ([2012](#)) sums up the global situation nowadays.

The *IPCC Special Report* warns that climate and weather extremes are getting more frequent and powerful in the twenty-first century even though only 0.5 °C increase in temperature had been detected in the past decades since 1950 (IPCC, [2018](#), 6). Thus, the “New Normal” is about “unexpected” frequencies and intensity of hazards. According to the same report, “the worst is yet to come” (IPCC, [2018](#)). Referring to the case of the totally unexpected power of Super Typhoon Yolanda/Haiyan (for brevity, this chapter uses “Yolanda”) which struck the Philippines on November 8, 2013, experts warned that people have the tendency to relax in the face of unprecedented disasters because they rely on historical experiences of past disasters, which, luckily for them, they survived ([Myrén, 2015](#)). However, such complacency, in itself, may aggravate the disaster. This happened to the people in the affected areas of Yolanda, who did not know the meaning of “storm surge” and stayed in their houses believing that just as they survived the past storms, they would just breeze through it. As history tells us, around 7,000 in the Visayas Region died, the worst in the region’s history.

The challenge nowadays to Public Administration in general, and the bureaucracy in particular, is to deal with the unexpected challenges of the “Age of the New Normal,” i.e., disasters brought by climate change. The challenge is formidable because the bureaucracy – the offices and the people that manned them – are just as vulnerable to hazards as mankind. It behooves us to ask: Are bureaucracies, as idealized in the Weberian model, responsive to the challenges of the “New Normal”? What are its strengths and weaknesses? What mechanisms can be instituted to “prepare” for these challenges?

To answer these questions, this article briefly reviews literature on how the challenges of the “Age of the New Normal” affect the bureaucracy. Second, it dissects the strengths and weaknesses of the Weberian model of bureaucracy in the face of disasters. A full case study on a government hospital is presented in the third part. The hospital was chosen for a fuller discussion because, paradoxically, even

though it was given a national award in 2013 as one of the best government agencies in disaster response, it fell victim to the super typhoon in spite of all of its preparations and years of experience in disaster/emergency situations. Lastly, the chapter briefly presents the “Public Sector Continuity Planning” of the Philippine government in response to the need to prepare its bureaucracy to survive disaster after disaster so that it could recover immediately and render post-disaster services to victims.

Bureaucracy for Emergencies

Rigidity in Bureaucracy: The Limitations of the Bureaucratic Model During Disasters/Emergencies

In times of disasters, governments respond through what is sometimes pejoratively called “bureaucracy.” Max Weber’s ideal-type of bureaucracy is the model which most of the countries in the modern time have adopted. To Weber and other authors, the bureaucracy is “a general way of organizing human activity so that complex tasks can be carried out in a coordinated, routine, and efficient manner” (Schneider, 2011, 47). The five most common characteristics of it are: (1) clearly defined objectives, (2) a division of labor, (3) a formal structure underlying the process and tying together the various component organizations, (4) a set of policies and procedures guiding organizational activity, and (5) specialized training, expertise, and experience (Schneider, 2011, 47). These constitute what is known as “bureaucratic norms.” These bureaucratic norms work best in stable conditions. The bureaucracy will function as long as these are followed. However, Schneider argues that these norms will have to contend with “emergent norms” which come out during disaster periods. They are norms that structure human behavior among the affected population that enable them to cope with the chaos brought by disasters (Schneider, 2011, 60). Its four basic components are: (1) milling, (2) rumor circulation, (3) keynoting, and (4) emergent norms. During disasters, people go to safe places to “mill” around with fellow survivors to search for meaning and appropriate standards of behavior. Rumors, then, begin to circulate which could be malicious accounts of ongoing situations. Those ideas and features that are repeated, while others are discarded, are said to be the keynotes, which transform into emergent norms once they dominate discussions and adopted as new set of behavior (Schneider, 2011, 55–57).

Gaps between the bureaucratic norms and emergent norms develop when there is a difference between governmental plans and the needs of affected population or disaster victims. The rigid, impartial, hierarchical, and rule-bound bureaucracy may not be able to respond to their needs. First, the goals and objectives of the bureaucracy are defined by laws, policies, and procedures imposed by the government. Any deviation from them to meet victims’ expectations will be treated as unlawful

actions, e.g., emergency purchases that violate the procurement law. Second, in times of emergency, government offices are not flexible enough to attend to people's needs. The division of labor among agencies have to be respected and their expertise has to be trusted to avoid duplication of services and wastage of government resources. Third, the organizational hierarchy, from top to bottom, has to be observed in authorizing actions and implementing them. In times of emergencies, this could spell a difference in evacuating residents or letting them become potential disaster victims.

The gaps may continue to widen because of five factors. These are: (1) magnitude of the disaster, (2) degree of administrative preparedness, (3) level of communication and coordination, (4) goals of governmental response system, and (5) prevailing orientation and behavior patterns of the affected populations (Schneider, 2011, 61). The bigger the catastrophe, the more the government may not be able to meet victims' expectations for speedy rescue, relief, recovery, and rehabilitation. The disaster preparedness of the government, guided by sets of procedures and protocols, may either not be followed during emergency situations or may not be congruent with the needs of the victims. Owing to the rigid hierarchies of government agencies, failure in communication and coordination is inevitable. Thus, government officials and employees may not be able to receive information and instructions both from the top and the bottom of the hierarchy. The changing or shifting goals of governmental response systems may obscure effective disaster response. If burdened with so many tasks through time, e.g., adding non-essential or unrelated tasks, disaster management agencies may find it difficult to pinpoint their objectives and priorities in times of disaster. Finally, the community or society's values, culture, or thinking may either support government's disaster management activities if the former is closely-knitted or make things complicated if people are uncooperative (Schneider, 2011, 61–67).

Other literature supports the contentions of Schneider. Learning from the dismal Hurricane Katrina post-disaster management, Takeda and Helms (2006) enumerate three failures of the bureaucratic approach towards disaster management. These are: (1) decentralized knowledge and centralized decision making, (2) ignoring outside information, and (3) commitment to failing courses of action. According to the authors, the sharing of codified knowledge built within an organization whose staff became "experts" in their own right takes some time to be passed to frontline local governments. Moreover, actions which require approval from the central office of a hierarchical organization cause delay in disaster response. And, due to the inbreeding of knowledge within agencies, there is a tendency among personnel to ignore relevant outside information, which is defined as "as any information, individual or activity which is not currently part of a system, but relevant to the task(s) faced by the system" (Takeda & Helms, 2006). This usually happens when scientific data contrary to those the government agency generated challenge those of the latter. Instead of reconciling, government agencies might defensively refute alternative data without assessing its validity. The result may be that the agencies fail to take appropriate actions, to the detriment of disaster victims.

Public Service Continuity Planning: Helping the Government Provide Continuous Services in Disaster/Emergency Situations

Disaster planning has been largely adapted and widely practiced for a long period of time. Whether there are natural, technological, contextual, or human-induced hazards (Wasley, 2013) that pose risks to the social, economic, and natural capital of a community, region, or country (Wasley, 2013), disaster planners have come up with counter measures to mitigate their effects. They have created emergency, preparedness, recovery and rehabilitation plans in the pre- and post-conditions of governments, business enterprises, communities, and other social entities. It is only in recent years that they have popularized continuity planning in the public and private sector, following the September 11 terrorist attack (Savage, 2002; Schneider, 2011) and other real-world events that increase the awareness to prepare and take action (FEMA, 2011).

The U.S. Department of Homeland Security describes continuity planning as “simply the good business practice of ensuring the execution of essential functions through all circumstances, and [it is] a fundamental responsibility of public and private entities responsible to their stakeholders,” (USHSC, 2007). In the context of business operations, continuity planning serves as a proactive measure to ensure that critical products and/or services are delivered during a disruption. These products and/or services must be rendered for the survival of the business enterprise, prevention of injury, and meeting of legal and other. On the other hand, continuity planning in the context of public service is a political safeguard to ensure an uninterrupted succession of the constitutional form of government in the face of any hazard that could pose threats to its constituents. It is integrated into the daily operations, functions, plans, and mission areas of government departments and agencies, and simultaneously occurs with the development of their programs (USHSC, 2007).

In the wake of the disastrous events that struck the USA, President George W. Bush’s administration pushed for extensive policies to counter terrorism and enhance national preparedness for disasters. In 2007, they issued a National Continuity Policy (NCP), which is an updated, integrated public continuity plan that aims to maintain a comprehensive and effective continuity capability for the preservation of their government and continuing performance of their functions broken down as follows: Mission Essential Functions (MEFs), Primary Mission Essential Functions (PMEFs), and National Essential Functions (NEFs). The MEFs are the government functions that must be continued after a disruption of normal activities in the department and agency-level. The PMEFs, on the other hand, are the specific MEFs that support the NEFs before, during and after a disruption. They must be continuously performed or must be restored within 12 hours after an emergency, and maintained for up to 30 days or until normal operations are resumed. Lastly, the NEFs are the overarching responsibilities of the Federal Government to lead and sustain the nation in the aftermath of an emergency (USHSC, 2007).

The four key pillars of continuity are leadership, staff, communications and facilities (see Fig. 1). All these components are significant during day-to-day operations but become critical in times of crisis (USHSC, 2007).

Fig. 1 The continuity policy framework. (Source: USHSC, 2007)

Leadership refers to the senior decision-makers that are in command of an organization (e.g., President, Cabinet Secretary, Governor, Chief Executive Officer, or manager). As supervisors to the continuity of operations, they are given physical protection (e.g., sheltering in a secured place or relocation away from the threat) in the imminence of danger. A prioritized list of designated successors is also accomplished in advance to ensure the survival of leadership. The successor serves as the “person to act for and exercise the powers of the principal in the event of death, incapacity, or resignation” (USHSC, 2007).

Staff are the “personnel that provide [the] leadership advice, recommendations and [the] functional support necessary to continue essential operations” (USHSC, 2007). Like the leaders, they are also cross and vertically trained to continually perform their duties with their peers and with the person above and below in times of disruption.

Communications refer to the “voice, video and data capabilities that enable leadership and staff to conduct their essential functions” (USHSC, 2007). It must be durable and reliable substantially in times of crisis. It must also be interoperable so that public and private organizations are linked, and can receive and transmit important information.

Facilities are the locations where leaders and staff perform their essential functions. There must be a designated facility intended for daily operations and alternate facilities for relocation. They must be sturdy and resilient, and must provide protection for the continuity operations. The leaders and staff may physically work in one facility or distribute in various sites (USHSC, 2007).

Public Service Continuity in the Eye of the Storm

When Super Typhoon Yolanda, one of the strongest typhoons ever recorded in the Philippines with its wind speed up to 300 km/h, made its landfall on November 8, 9 out of the 17 administrative regions in the Philippines were affected by its strong

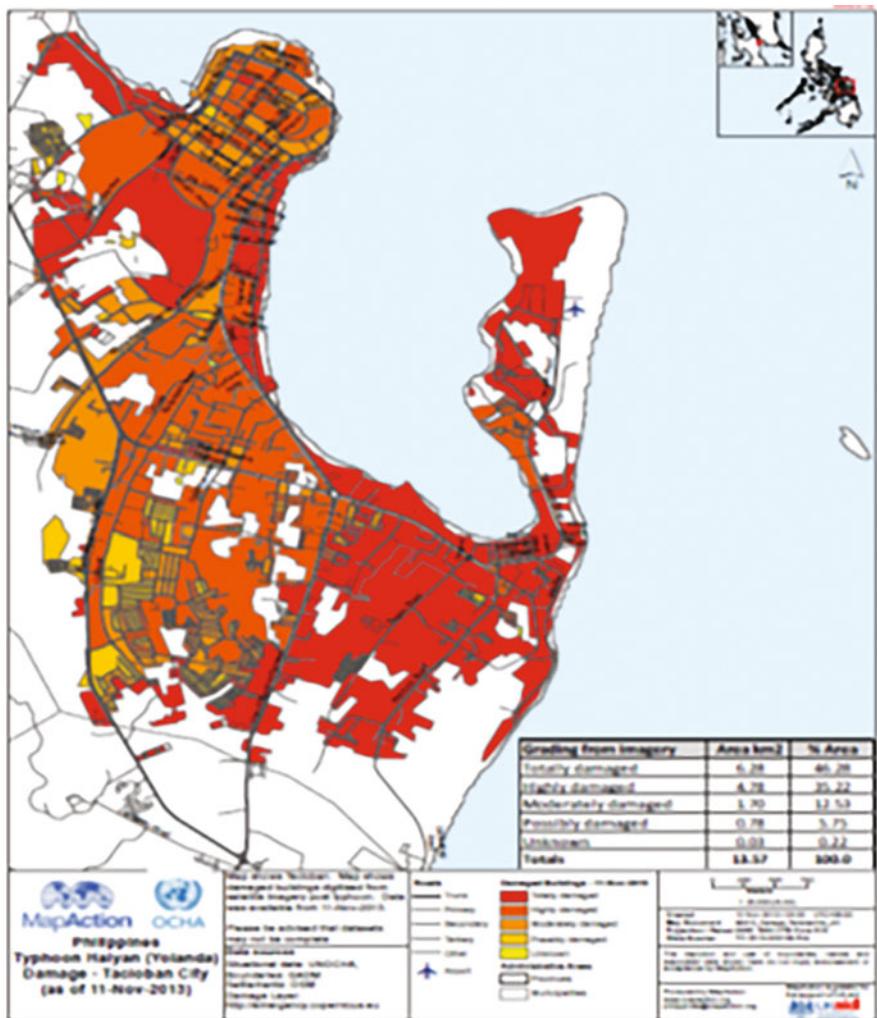

Fig. 2 Areas in Tacloban City affected by the storm surge. (Source: UN-OCHA, 2014)

winds and the storm surge that came with it. This includes Tacloban City, which is considered as the regional hub of the Central Visayas region. The province's eastern part was heavily damaged by the storm surge, which rose up to 6 m high (see Fig. 2). The fatalities were estimated at 7,000 and the number of missing persons at 1800. Moreover, the number of damaged houses reached up to 28,734. Out of this number, 90% were along the coastline. Partially-damaged houses totaled to 17,643. Major damages were also sustained by all of Tacloban's seven hospitals and clinics.

The Case of the Eastern Visayas Regional Medical Centre⁴

Background

One of the hospitals which was heavily damaged was the Eastern Visayas Regional Medical Centre (EVRMC). EVRMC is a regional, tertiary, teaching-training health care facility established in 1966 with 275 bed capacity. In 2013, it had 389 health manpower complement consisting mainly of doctors (27%) and nurses (40%). It is an “apex” hospital or the “end-referral” hospital where all the lower health facilities, patient transport services and volunteer emergency responders bring their patients for definitive management, especially patients during emergencies and disasters.

EVRMC has proven that it is capable of living up to its functions in times of disasters. Prior to the November 2013 disaster, the hospital responded to 12 emergency/disaster-related cases, ranging from man-made (fire, collision, car falling off from cliff or to canal, landslide, flooding, typhoid fever outbreak, search and rescue mission) to natural disasters (earthquake and typhoons).

For outstanding medical contributions to emergency/disaster responses in other areas, EVRMC was awarded on October 25, 2013 by the Office of the Civil Defense (OCD) the 2013 *Gawad Kalasag* (Shield) National Award: Best Hospital (Regional and Training Hospital Category). It was barely a month before the super typhoon brought the hospital down.

Preparations

Having been accustomed to disasters, EVRMC took immediate actions as early as November 6 in anticipation of the visit of the super typhoon. The chief of hospital raised the “Code White” alert (the first level among the 3-level Code Alert System) through the issuance of Hospital Memorandum (HM) No. 189, s. 2013, which instructed the following personnel to be present and man their stations during the entire duration of the latter:

Senior house officer	Nurse supervisor residents on duty –
Residents on duty –	
Orthopedic	Operating room staff and personnel
Internal medicine	Institutional workers
Family medicine	Radiologic technologies.
Ob-Gyn	Pharmacist
Surgery	Medical technologist
Eyes, ear, nose, throat	Admitting unit
Psychiatry	Ambulance driver
On-scene response team (EMTs) – Composed of 14 doctors and staff	Maintenance crew
	Security guards

In addition, all concerned departments/sections/units were instructed to prepare in accordance with the alert level, and send flash report of any untoward incidents to the operations center of the hospital.

On November 7, 2013, the chief of hospital issued HM No. 192, s. 2013 suspending work starting the afternoon of that day until the next day when the super typhoon has made landfall in Tacloban City. However, the following units

were requested to keep skeletal forces during the entire duration of the typhoon visit: admitting, pharmacy, billing and PHC claims unit, cash section, laboratory, radiology, and facility and maintenance.

The staff of the Clinical Department was ordered to maintain its working force in support of the “Code White” alert or higher level codes. On the day of the visit of the super typhoon, the hospital had a total ward census of 331, and around 66 personnel on duty.

Loss and Damage

However, in spite of all the preparations and its experiences in responding to disasters, the hospital became one of the victims of the super typhoon. After the wrath subsided, 5–90% of the hospital’s buildings/infrastructure were damaged. Its desalination plant and water treatment plant suffered the most. Except for three places, all of the offices got flooded and their equipment were either partially or completely destroyed (refer to Table 1).

Table 1 Damage sustained by various EVRMC structures

Building/Infrastructure	% Damage	Flooded	Equipment damage
Desalination plant	90%	Yes	100%
Waste water treatment plant	80%	Yes	100%
Tropical & Infectious Diseases Building	30%	Yes	100%
SARS (severe acute respiratory syndrome) building	50%	Yes	100%
SAO & CN quarters (housing the offices of the supervising administrative officer and chief nurse)	30%	Yes	100%
Chief of hospital quarters	30%	Yes	100%
Supply office	25%	Yes	100%
Laundry & Linen Building	40%	Yes	50%
Engineering & Maintenance	15%	Yes	50%
Powerhouse & Generator	15%	Yes	100%
Morgue	50%	Yes	NA
Incinerator	50%	Yes	NA
Dietary	10%	Yes	None
Out-patient department	90%	Yes	Yes
Administration building, including Pharmacy & Emergency Complex	10%		Partial
Main building (patients’ wards)			
Internal medicine Ward/intensive care unit	15%	Yes	Partial
Internal medicine Ward/Ob-Gyn Ward	10%	Yes	Partial
Pediatrics/Ob-Gyn Ward	50%	Yes	Partial
Operating room complex/labor room/delivery room	25%	Yes	Yes
Laboratory	5%	Yes	Yes
Philippine health insurance corporation I/orthopedic	50%	Yes	Yes
Philippine health insurance corporation II/general surgery	15%	Yes	Yes

Casuals	4	2	0	2
RN heals (registered nurses for health enhancement and local service)	169	78	1	91
Job orders	135	76	0	59
Security guards	15	14	1	0
Total	664	361	4	301

Source: Ruetas ([2014](#))

The hospital's personnel were also hit hard by the super typhoon. When an unnumbered Hospital Memo was issued on November 20 requesting all personnel to report to duty starting November 25, many failed to show up. Out of the 680 staff, 44% or 301 of them were not able to immediately report. Unfortunately, two medical staff and two administrative personnel (1%) died during the typhoon's onslaught. Luckily, 375 personnel (or 54%) went back to duty immediately (see Table 2). Those who reported struggled to do their jobs in spite of the damages sustained by the hospital and its equipment, the shortage of medical supplies, and the bleak conditions in the city.

Recovery Efforts

In spite of the damages it sustained and loss of lives of its personnel, the hospital continued to provide its services as a critical community facility during and after the visit of the super typhoon. In fact, EVRMC was the last hospital standing in the aftermath of the disaster despite the depleted manpower and logistics (Ruetas, [2015](#)). The table below shows the dedication of its staff to its oath to serve people in dire need of medical assistance even in times of disasters. From 7 to 22 of November, on the average, the hospital admitted 42 patients, adding to its in-patients averaging 220 each day. As quickly as it admitted patients, the hospital discharged 47 on the average each day. Unfortunately, among those admitted during the said period, 49 of them died (see Table 3).

EVRMC was assisted by many to continuously give medical services immediately after the disaster, and to recover immediately from the devastation. These include local governments, local hospitals, national government agencies, UN organizations, local and international private corporations/foundations and foreign countries (Ruetas, [2015](#)).

Continuity Planning for the Future

In reflection, the hospital learned that even though it was a national awardee on disaster response that very same year and had lots of experience in responding to disasters in other provinces, it lacked plans, effective communication system,

Table 3 Hospital census, November 7–22, 2013

Date	Admissions	Discharges	Mortality	In-patients
Nov. 7	56	64	5	331
Nov. 8	29	3	1	346
Nov. 9	28	30	4	340

Total	664	757	49	N/A

Source: Ruetas ([2014](#))

transportation system and units, logistics, and lifelines. Moreover, it realized the problem of their staff as victim-responders, i.e., they are also susceptible to the hazards, hence, may not be able to report immediately to the hospital to perform their duties. To address these gaps, EVRMC drafted its *Hospital Emergency Preparedness, Response, and Recovery Plan (HEPRRP) 2014–2015: Contingency Plan, Business Continuity Plan* in 2014. The manual “defines the direction of the hospital in preparing for effective and efficient response and recovery in any event of emergency or disaster within its facilities and/or its catchment area” (EVRMC, [2014](#)). The over-all goal of the new systems put in place is to decrease mortality and morbidity in times of disasters. Four plans have been drawn up in details. These are the:

- **Preparedness Plans** – contain strategies and activities that the hospital shall carry out, all geared toward the building and enhancing of the hospital capacity to address all types of emergencies and on disasters.
- **Response Plans** – include the established strategies and activities defining the utilization of the hospital resources for an effective and efficient response during emergencies and or disasters. This includes specific policies, protocols, guidelines and procedures pertaining to various emergency management systems for a more efficient and calculated response.
- **Hospital Recovery or Rehabilitation Plans** – include any and all strategies and activities which will bring back the hospital to its status quo condition antecedent to the occurrence of the emergency and/or calamity in order to prepare the same for any other forthcoming eventuality.

- **Contingency Plans** – systems and standard operating procedures in establishing and sustaining surge capacity of the hospital. Its objective is to maintain continuous hospital operation during disaster.
- **Business Continuity Plan** – includes systems and standard operating procedures on how to continue critical functions of the hospital without interruptions. It contains logistical plans with strategies, mechanisms, arrangements, systems and procedures on how to continue operations. Includes support to operation in terms of resources such as manpower, logistics, finances, information, lifelines and accommodation, among others.

Systems and procedures were also drawn up for to verify reports of impending hazards/disasters, management of victims in the “tent emergency room,” standard operating procedures on the conversion of the hospital’s parking lot into triage, collection and treatment area, and mechanism for the activation of the plan for external disasters.

The hospital created its EVRM Planning Committee with the Chief of the Medical Centre, as the chairman (alternative is the HEMS Coordinator) with members composed of the heads of the various clinical departments or their representatives, i.e., the administrative officer, the chief nurse, the security officer, head of the maintenance division or their representatives.

Analysis: The case study above has shown that EVRMC’s bureaucracy is well-experienced in dealing with emergency situations. However, its high level of preparedness, and long years of experience in dealing with emergency situations, as fully narrated above, were of no match to the power of the super typhoon. Still, it persevered to serve the people of the Eastern Visayas region even though the hospital itself was handicapped by the damage to its building, equipment, and facilities, and casualties and injuries to its personnel. It lived up to expectations when it continued its operations during and immediately the disaster has struck.

Institutionalizing Public Service Continuity Planning in the Philippines

On 10 April 2018, the NDRMC, through its Memorandum No. 33, s. 2018, called on all government member-agencies of the council at all levels and other government departments, offices, bureaus, services, units, and instrumentalities to develop their own Public Service Continuity Plans (PSCPs). This was after a decision was made at the fourth Meeting of the Cabinet Cluster on Climate Change Adaptation, Mitigation, and Disaster Risk Reduction “to guarantee the continuity of operations amidst disruptions.” The concept of the PSCP was developed through the joint-collaboration of the OCD, NDRRMC TWG, and Philippine Disaster Resilience Foundation (PDRF).

A PSCP is officially defined as “a document containing strategies and mechanisms of a government agency/ organization to ensure continuous delivery of services to the public amidst any disruption” (NDRRMC-PDRF, 2018). Specifically, PSCPs are drawn to:

- Ensure continued performance of essential functions – essential functions are those services that must be delivered amidst any disruption.
- Minimize damage and loss to critical processes – critical processes are all internal to your organization.
- Ensure succession if agency leadership is disrupted – such will allow continuity of leadership roles by having backup leadership positions.
- Reduce or mitigate disruptions to operations – your government agency can still perform your mandated roles.
- Ensure facilities for performance of essential functions – the infrastructure and facility requirements will be in place so that you can perform your essential functions.
- Protect essential facilities and resources – aside from essential functions, the facilities and resources that support the performance of your essential functions are also secured from the threats.
- Achieve a timely and orderly recovery.
- Resume full service to customers.
- Maintain a test, training, and exercise program (NDRRMC-PDRF, 2018).

Conclusions

Theoretically speaking, the literature points out that the strengths of the Weberian model of ideal-type of bureaucracy is also its weakness during times of emergencies. The Weber-inspired bureaucracy assumes a stable condition such that it creates its bureaucratic norms which makes it inflexible to respond immediately to emergent norms of disaster victims who need help to cope with their personal losses and the destruction in their environment. Hence, gaps between the government's bureaucratic norm and the victims' emergent norms develop. These gaps may still widen depending on the nature and power of the disasters, the preparedness of the governmental response systems, and people's orientation and behavior towards disasters and their government. The case of EVRMC has shown that years of experience in disaster/emergency response may not be enough to withstand powerful hazards in the "Age of the New Normal." Hence, continuity planning for various disaster scenarios may still prove to be useful to lessen, if not eliminate damage, losses, and casualties.

Abstract

The welfare provisioning and distributive justice in a pandemic, as seen in the context of the current worldwide COVID impact, assume particular importance for achieving the goals of inclusive development. The world has, undoubtedly, witnessed in recent times average gains in material prosperity with gross domestic product per capita doubling in low- and middle-income countries. But, even with the world becoming richer, poverty and destitution continue to be experienced by a large population living on the margins of this growth story. It is a pandemic and a disaster that is axiomatic in the development policy context for structuring policies and institutions for inclusive governance. It is in this context that this

Research Scholar, Tata Institute of Social Sciences, Mumbai, India

chapter looks at the policies and interventions made by the government in India, for the incorporation of productive capacities of the poor and marginalized post the COVID pandemic impact through the numerous welfare policy initiatives. The focus of this chapter is on the policy interventions pertaining to agriculture services, food security, livelihood and employment, public health, and WASH (water, sanitation, and hygiene) programs. The chapter attempts to provide an understanding of, and a mapping of, the operational issues that underlie challenges and opportunities for inclusive governance across rural areas and urban areas (in urban areas, the focus being on slums). In the rural context, the chapter looks at the policy provisions for agriculture, food security, and employment; and in the slum settlements in urban areas, issues of health and WASH are covered along with food security policy for the urban poor. These domains are critical to addressing the immediate challenges of distributive justice and well-being in a pandemic, as they are central to concerns of livelihood and affordable living. In the same context, these domains are significant to develop a framework of inclusive governance and build an understanding of the institutions for inclusive development. The chapter makes important policy inputs for structural interventions, involving public administration/government, private sector, and civil society, for governance in a pandemic. The chapter draws on government notifications and guidelines, projects, and initiatives conducted through corporate social responsibility initiatives by the private sector and civil society groups in slums and recommends how convergence between these groups and initiatives can be met going to support efficient capital and human resource.

Inclusive governance · Institutions · Distributive justice · Pandemic

Introduction

Since the SARS-CoV-2 outbreak in India, there is an increasing attention paid toward the role of “essential goods” and what does it constitute. This has been made clear in the response of the India government presented in terms of the economic and structural reforms package introduced in mid-May 2020 (Press Information Bureau, 2020) (see Table 1). It is within the scope of this response package and in particular the structural reforms introduced by the central government that this policy brief attempts to answer the policy question of how challenges concerning local governance structures be addressed in order to direct and devolve resource for people’s well-being in the urban and rural context. The immediate or essential domains, as evident from the central government’s recent announcements, have been areas of agriculture, food security, employment, and health. In keeping this as the focus of this policy brief, the study discusses the macro-level challenges of federalism and outlines a contextual understanding of local governance and institutional capacity to operationalize such structural reforms.

Table 1 Allocation of funds as part of the stimulus package by the Government of India

S. no.	Major heads	Amount (in Cr.)
1	RBI fiscal stimulus	801,603
2	Liquidity infusion	245,000
3	Linked to farmers	247,400
4	Agriculture	150,000
5	Collateral loans to small businesses	391,000
6	Welfare related	260,435
7	Total package	2,095,438

Source: Accountability Initiative (URL: <https://public.flourish.studio/visualisation/2443098/>)

In India, the quasi-federal structure gives space for governance at three levels: central, state, and local. The 73rd and 74th Constitution Amendments Acts (CAAs) provided constitutional status to local bodies in India, and laid down the importance of “local” governance, in the period that saw the introduction of the structural adjustment programs. In line with this, focus has been toward understanding the devolution of funds, functions, and functionaries, in policy and practice.

The following section (Section “Building the Context”) presents the context for this discussion. Section “Key Policy Principles” highlights the challenges concerning the role of local governance, issues of inclusion, and well-being during COVID-19. Following this, section “COVID-19: Conceptualising Inclusive Governance” presents a critical discussion on contextualizing inclusive governance in handling a disaster like the COVID-19 pandemic. Section “Access to Welfare: Institutional Restructuring” highlights the institutional restructuring needed to strengthen governance and distributive justice. The concluding remarks are presented in the final section.

Building the Context

The emergence of SARS-CoV-2 had brought far-reaching impact and transformative changes in the social, economic, and political sense. The impact and transformation in terms of social life and livelihoods has brought underlying structural and distribution challenges to the forefront again. This is primarily due to the global nature of this virus, and the way in which the SARS-CoV-2 has infected urban areas, especially in India. In this context, the urban areas have highlighted immediate issues in terms of physical health and WASH infrastructure at the local body level as well as access and affordability of food and housing. The second part of this, food and housing, has brought major burden on the daily wage workers residing in cities and migrant populations to migrate back to rural areas amidst the national-wide lockdown. This in turn has brought upon additional burden on rural employment and food security along with distribution of agriculture produce from the preceding season and rabi season in India.

In urban areas, a large focus has been in areas of high population density and informal settlements; studies indicate they are more vulnerable to the outbreak (Corburn et al., 2020; Patranabis et al., 2020). These types of urban settlements are extremely vulnerable to SARS-CoV-2 due to the lack or no availability of basic health and WASH facilities. The instable and inadequate economic condition of these families makes them doubly vulnerable to such outbreaks. As literature points, the role of communities and community leaders within these informal settlements becomes fundamental to containing the spread and for authorities and support groups to help them. These community-driven solutions are the first step that local bodies need to actualize for access to food and affordability of essential services. These issues question the sustainability of metropolitan cities.

Key Policy Principles

Information and Communication

The domain of information and communication is crucial to addressing issues of asymmetry and inadequacy in a governance process. In providing a system of transparent and account system of information, the highlighted issues can be addressed, beginning at the community level. In understanding the role of information in governance process, especially at the local and community level, studies indicate how asymmetrical flows of information can lead to market failures.

The role of information is important to each stakeholder for an inclusive feedback loop. In this case, the role of community radio and campaigns at the grassroots are discussed and proposed, especially for its benefits and targeted nature for the beneficiaries. At a community level, and in the process of governance, these channels act as important means through which asymmetries are tackled and mitigated. Therefore, an effective information and communication strategy is crucial to address challenges in the abovementioned areas and act as a key principle for exploring, understanding, and examining measures undertaken.

Community-Driven Solutions

This principle of community-driven solution has become crucial to identifying and addressing the level at which governance can be possible. In the particular context of urban areas, informal settlements are seen as extremely vulnerable spaces in India and across the Global South, raising questions about the challenges to health and WASH conditions therein.

The informal nature of these settlements makes it difficult to navigate and organize programs, and where the role of “slum leaders” (Auerbach, 2020) becomes an important feature. They are central in availing resources and act as the link

between any form of social and economic intervention in the community. Such “durable and active forms of informal leadership” are a feature of these leaders, and where aspects of trust and fear (Corburn et al., 2020) play an important role in access to health and other essential services in the governance process; any governance process needs to understand the strong presence of resistance and violence within these communities toward government authorities and “outsiders” as the basis for governance planning and process.

Structural Integration

In identifying local government agencies, corporate social responsibility, or CSR foundations and civil society, it is important to highlight integration and emphasize on the processes at the grassroots. While there is a broader aspect of federalism at play, in terms of the center-state-local cooperation during the SARS-CoV-2, as this policy brief has highlighted, the role of bottom-up approaches is crucial to achieving inclusive governance and addressing challenges of institution capacity through such integration at a community level across India.

While central and state governments have mapped important areas, when it comes to local interventions, authorities will provide economic and logistical room and flexibility in governance. The total expenditure by CSR foundation in India was Rs. 8691 (KPMG, 2020) for 2018–2019. India’s CSR Survey for 2019 indicates that 80 percent companies have a preference to spend locally:

88 per cent companies have implemented projects in the locality of their presence (neighbourhood). This truly indicates India Inc. willingness to contribute for wellbeing of stakeholders (largely communities) around its operations, which indirectly may also result in enhanced brand recall among such stakeholder groups. (KPMG, 2020)

There has been a reported trend of a growing partnership with implementing agencies within the CSR space. Therefore, collaborations and partnerships can facilitate cooperation and create transparency and accountability in the governance process through regular reporting, monitoring, and assessment of activities.

COVID-19: Conceptualizing Inclusive Governance

In using inclusive governance to develop response in terms of addressing structural and systemic challenges at the local self-government amidst the pandemic outbreak, three key tenets are important. These are to explore and understand responses on the part of government, private organisation, and civil society and examine these responses in light of the existing structural and systemic gaps.

For example, research focusing on “factors that can strengthen implementation and accountability and empower individuals to claim their entitlements” has

provided evidence to support where the central government has failed to mandate such necessary reforms. For example, to make the PDS functional across India, individual states and territories will have to take the initiative to fill the gaps (Sekher et al., 2017). Similarly, in urban areas, issues of health and WASH are to focus upon with urgency and sustainability in their response to address the existing fractures. This requires “community-led committees” to be “empowered to lead on the public health and disease messaging, including avoiding xenophobic and racist falsities, and help decide the appropriate use of technologies in communication to those who may be illiterate or have minimal health or science education” (Corburn et al., 2020). Likewise, the role of CSR in the social security space needs to be contextualized within the decentralization argument, because of its focus on community and local areas (KPMG, 2020). The distribution of CSR funds at state-level across sectors, decentralization, and impact of COVID-19 need to be problematized together for understanding each area and plan a course of action.

Assessment of Domains: Challenges and Measures

There is a wide range of literature indicating the structural constraints rooted in the reforms proposed, and why these as fractures in the welfare system require urgent attention. The role of local governance and decentralization are central to the type of micromanagement needed to address challenges and implement these reforms for effect and efficient targeting and implementation. The role of civil society, CSR, and an inclusive local planning on the part of local bodies, to leverage support, can guide measures to ensure well-being in policy and practice terms.

Rural

In the rural economy, the changes in agriculture brought as part of the emergency economic package and how far do they go to address the needy and vulnerable groups remain a critical question. In addition, the emphasis on creation of physical infrastructure capacity and giving farmers greater freedom to sell their produce calls for addressing scarce income resource in the hands of the rural population, data and information on coverage of schemes, and gaps within the regulatory framework.

The agriculture sector in India was entering the rabi crop harvest stage when the impact of COVID-19 gradually increased and the national lockdown was imposed. In addition to the structural problems existing in the agriculture sector, the Indian Council of Agricultural Research (ICAR) on behalf of the agriculture ministry and the Government of India laid down state guidelines too. Regarding provisioning of schemes and funds toward agriculture, farm sectors such as coconut extraction, tea, etc. have received attention across the frame by India Inc., but a large sector of them still rely on government schemes and informal credit system.

Challenges

- Lack of access to collection agents for forest produce in tribal areas due to the lockdown.
- Borrowing of informal loans by farmers at higher rates further escalates the socioeconomic vulnerability of small-scale farmers and other rural groups.
- The agriculture sector was exempted from the lockdown only in mid-April with the immediate challenge being observed as “dissemination of the guidelines and implementation on the ground” (Bhavani, 2020).
- The distress farmers found themselves in “the first few weeks, with no clarity about exemption to agricultural work, and local police kept disrupting the work” (Rawal & Kumar, 2020):
 - The issue of fall in demand for perishable items such as “vegetables, fruits, milk, eggs, and poultry” (Rawal & Kumar, 2020).
 - There is an impact on the cultivation of interim crops sown between rabi and kharif seasons (Anju, 2020) due to delay in the cultivation and selling of rabi crop.
- The issue increased with shutting down of mandis in the first phase of the lockdown and with certain mandis being identified as ‘superspreaders of coronavirus’ (Rawal & Kumar, 2020) that led to their closing down.
- Agriculture inputs, public procurement, etc. (Rawal & Kumar, 2020).

Measures

- As part of the aid package announced by the central government, a total of rupees 150,000 has been allocated to agriculture directly (see Table 2).

Table 2 Agriculture: Atmanirbhar Bharat economic package

S. no.	Heads	Amount in Cr.
1	Agriculture and infrastructure funds	100,000
2	PM Matsya Sampada Yojana	20,000
3	Cultivation of herbal plants	4000
4	Animal husbandry and development	15,000
5	Micro food enterprises (MFES)	10,000
6	Operation green	500
7	Beekeeping initiative	500

Source: Accountability Initiative, <https://public.flourish.studio/visualisation/2443098/>

Table 3 Linked to farmers: Atmanirbhar Bharat economic package

S. no.	Heads	Amount in Cr.
1	Credit through kisan cards	200,000
2	Working capital for farmers	30,000
3	PMKISAN (PM-GKY)	17,400

Source: Accountability Initiative, <https://public.flourish.studio/visualisation/2443098/>

- In terms of initiatives linked to farmers (see Table 3), the package provides for Rs. 247,000. This includes funds toward credit through kisan cards (Rs. 200,000), working capital for farmer (Rs. 30,000), and PM-KISAN (PM-GKY) (Rs. 17,400).
- In addition to the aid package, guidelines through Indian Council of Agricultural Research include national- and state-specific guidelines to be followed in the light of the ongoing and upcoming agriculture season (Pothan et al., 2020).
- Addressing issues at the local level to the food system and “crop-specific safety measures regarding harvesting, post-harvest operations” (Pothan et al., 2020).
- Accordingly, “responsibilities were given to local field agencies to ensure hassle-free movement of agricultural produce and related machinery to reinstate farming activities” (Pothan et al., 2020).
- Providing market understanding to farmers through conferences, giving them information and expert perspective, and linking farmers to local government officials and policy experts.
- Similarly, corporates are investing in formal, commercial agriculture sectors such as tea and coconut cultivation among others in different parts of the country, giving them agriculture support and creating awareness and health and WASH equipment.
- Providing access to storage and help in terms of supply chain challenges during the lockdown.
- To a similar extent, CSOs are also working on similar lines as CSR, as both partners and individuals in providing:
 - Logistical support through collaboration.
 - Technology: use of mobile applications in addressing supply side gaps.
 - Connecting with farmers in remote areas and identifying them through special programs.

Food Security: can be ensured in terms of availability, access, utilization, and stability (FAO, IFAD, UNICEF, WFP and WHO, 2021) of food and nutrition.

Challenges

- There is heavy reliance on PDS systems for rural populations to get food. This brings a lot of structural burden on governance structure, leading to delays and poor service delivery.
- Besides making food grains available through PDS, the FCI also has to sell the surplus grain through the Open Market Sales Scheme (OMSS), often at a loss (Rawal & Kumar, 2020).
- State governments also need to buy these grains at full economic cost (Rawal & Kumar, 2020) under the OMSS for food security schemes beyond the NFSA.
- Similarly, the urban migrants are excluded from the targeted schemes, as benefits are linked to their residence address in their villages, as listed in their aadhar cards, and, due to this, during the COVID lockdown, many stranded migrants remained vulnerable and faced food insecurity.
- Reports suggest rural India households reduced the number of meals they took during the COVID lockdown, and also there was a reduction in their food

(68 percent), as they reduced the total number of items taken in their meal (PTI, 2020).

Measures

- As part of the aid package announced by the central government, Rs. 3500 crore has been allocated toward free distribution of food grains for 2 months (April and May) “to about 8 crore migrant labor who are not covered under NFSR or state scheme PDS cards” (see Table 4).
- Rs. 40,800 allocated toward food grains under Pradhan Mantri Garib Kalyan Yojana.
- CSR Foundations have used the existing community projects to work with and provide for food rations in these pockets.
- Due to the breakdown of supply chain and lack of volunteers, CSR finds it difficult to implement such programs outside of geographies where they have strong ground presence.
- While partnership with NGOs has been explored, there is little progress to this end.
- Similar attempts have been made on the part of NGOs in terms of providing food security in rural areas through ration distribution.
- These interventions also include facilitating COVID-19 test kits and other health support in inaccessible rural areas.

Employment: Amidst lockdowns and partial running of economy throughout the country, availability and access of livelihood opportunities were critical as migration at scale put a burden of existing capacity on schemes such as the Employment Guarantee Act. This can be observed in terms of the varied challenges to labor demand and supply over time and specific measures adopted to cope with these shocks (Mohapatra, & Hussain, 2021).

Challenges

- The labor work under MGNREGS was stopped as the national lockdown was imposed that severely impacted the laborers in terms of their livelihoods.
- Due to delay in the rabi season’s completion, and lockdown in place, the process was delayed – and farmers had to rely on the local or any available labor force.
- Due to the lockdown, machinery used in the processing of rabi crops was delayed along with challenges in transportation of the machinery:
 - These delays impacted other crop cycles and demand-supply dynamics, putting constraints on farmers.

Table 4 Food security:
Atmanirbhar Bharat
economic package

S. no.	Heads	Amount in Cr.
1	Food grains to migrants	3500
2	Food grains (PM-GKY)	40,800

Source: Accountability Initiative, <https://public.flourish.studio/visualisation/2443098/>

Measures

- As part of the emergency package, the central government has allocated (see Table 5):
 - MGNREGS additional funds amounting to rupees 40,000
 - MGNREGS (PM-GKY) amounting to rupees 37,825
- Support small business and self-employed individuals.
- Creating employment through making medical equipment as well as converting businesses that have hospitality wings to temporary quarantine facilities
- Supporting creation of job cards for in-migrants, proposing revisions to the Gram Panchayat Development Plan, and working directly with elected representatives
- Helping small businesses by manufacturing medical equipment for frontline workers in rural areas
- Supporting awareness drives and activities among women groups

Urban

Cities have been exposed to planning processes that have created inequality across various sectors, i.e., housing, health, water, etc. It has been earlier noted that India went into a nationwide lockdown with a 4-hour notice, and this left a large number of migrant population that had little or no financing capacity to economic survive in these cities. These groups, especially those living in informal settlements across cities, found themselves more vulnerable with their livelihoods lost and no resources to return home, in this case to their home state. The combined issue of access to health and food in these communities combined with the outbreak itself and ensuring social distancing and lockdown norms stretched the institutional capacity of these urban local bodies to its maximum. Corburn et al. (2020) note:

Immediate measures to protect residents of urban informal settlements, the homeless, those living in precarious settlements, and the entire population from COVID-19 include the following: (1) institute informal settlements/slum emergency planning committees in every urban informal settlement; (2) apply an immediate moratorium on evictions; (3) provide an immediate guarantee of payments to the poor; (4) immediately train and deploy community health workers; (5) immediately meet Sphere Humanitarian standards for water, sanitation, and hygiene; (6) provide immediate food assistance; (7) develop and implement a solid waste collection strategy; and (8) implement immediately a plan for mobility and health care.

These urban areas in India provide important lessons, especially when we combine issues of decentralization and top-down planning in cities with COVID-19

Table 5 MGNREGS:

Atmanirbhar Bharat
economic package

S. no.	Heads	Amount in Cr.
1	MGNREGS additional funds	40,000
2	MGNREGS (PM-GKY)	37,825

Source: Accountability Initiative, <https://public.flourish.studio/visualisation/2443098/>

outbreak. These informal settlements are extremely vulnerable socioeconomic sections and rely on extremely low-paying jobs and are excluded physically in terms of space and economically from the core of the urbanization process to the peripheries.

The Social Science in Humanitarian Action explaining the epidemiological vulnerability related to COVID-19 makes a case for population density, households and social structures, water, toilets and sanitation, and access to food:

In poor settlements, households have no capacity to store food for several days and source most of their food from informal markets and street food vendors. If movement is restricted, people's ability to access food will be severely reduced. Furthermore, if markets or food vendors are closed, this will mean people are not able to buy food they need. (Social Science in Humanitarian Action, 2020)

A key component in urban areas and especially among vulnerable groups is the issue of misinformation (https://opendocs.ids.ac.uk/opendocs/bitstream/handle/20.500.12413/15178/SSHAP_Brief_Online_Information_COVID-19.pdf?sequence=1&isAllowed=y) Key considerations: COVID-19 in informal urban settlements. 2020. Social Science in Humanitarian Action), an important area needing swift and timely intervention at the community level to tackle and address any problem of mistrust. There are other aspects of population density, congestion, and access to open spaces that come into consideration (when the lockdown opens). A recent study indicates:

Slums constitute 17% of urban households in India... analysis reveals that several of the existing Containment Zones in Mumbai are within or very close to slums. The reason for this phenomenon is likely to be difficulties in maintaining social distancing or hygiene standards and shared communal facilities including toilets. There are clear policy implications for this. One hypothesis is that the lack of secure property rights given to slum dwellers holds them back from getting better access to amenities and housing, which reduces their ability to safeguard themselves against rapidly spreading infections. (Patranabis et al., 2020)

In addition, eviction of slum population is an important question during the post-lockdown period that will essentially help understand the sustainability of livelihoods in these urban spaces. As noted, discussing issues of health and WASH as well as access to food within these communities in cities remains the primary focus of local areas and which this brief addressed as well.

Health and WASH: As cities emerge as nation and global hotspots of COVID-19, there are major issues around health and WASH to be considered, and how measures to this end have tackled and help mitigate the dangers, and similarly, what are the measures being adopted as cities open up to businesses – formal and informal – and how far do these measures cover operations at the community level for decentralized governance. In the abovementioned summary of concerns, as a background, these issues are central to challenges around health and WASH in cities. These challenges have been the focus of government, CSR, and NGOs to a large extent.

Challenges

- Lack of social security in terms of food and shelter for laborers working on daily basis in industries such as real estate, contractual workers in waste management, etc.
- High population density in cities, especially in informal settlements, increases difficulty for implementation of social distancing norms, isolation, and quarantine.
- Likewise, the issue of poor and no access to water is central to individual practices of hygiene such as washing hands.
- Unaffordable and inaccessible healthcare is another major concern for the weaker socioeconomic section, especially women and children:
 - The gender-based issues are another important factor to be considered while exploring health.
 - Similarly, health-related risk from water and its poor quality is another major issue.
- Communication and awareness about COVID-19 and the associated health risks these community may face are important parts of the social interventions.

Measures

- Increasing testing and creating capacity of hospital beds, including quarantine facilities.
- Implementation of central government orders in terms of health capacity creation, contact tracing, reporting of cases, etc.
- State government and local authorities: operationalizing process of migrants returning home via special trains.
- There are certain corporate foundations that have made special COVID-19 funds in addition to the related contribution to national- and state-level government funds working against challenges posed.
- The support of CSR in health and WASH has largely been in terms of providing:
 - Screening for symptomatic patients
 - Masks and sanitizers
 - Washing and cleaning soaps, sanitary napkins, and toilet cleaners
 - Medical equipment
- Such initiatives are both at the level of frontline staff working on COVID-19 and vulnerable populations residing or in the process of migration, migrants working in real estate sector, etc.:
 - Certain CSR initiatives also focus on working directly with hospitals as well as creating the physical quarantine facilities for local bodies.
- Organizing awareness drives through on-ground and online campaigns.
- Community-level partnership through CSR and local body support.
- A large number of activities include supporting and operationalizing their own programs in:

- Identifying critical and vulnerable masses in cities
- Awareness campaigns and sharing information on health safety and precaution measures concerning COVID-19
- Health support in informal areas and among migrants
- Distribution of WASH essentials
- CSOs worked both with CSR foundations and collaborated with local bodies to help map these groups.

Access to Food: In terms of collaboration and cooperation, providing access to food saw the most inter-participation among government agencies, private organizations, and civil society groups. These collaborated at various levels to identify and provide for access to food among different populations round the clock and on a daily basis. The collaboration between state and private or NGO was seen to be a major positive in the delivery of food.

Challenges

- Adequate access to food became a problem with economically vulnerable population saving money to return home with no work in hand.
- The cloud of uncertainty about going back to their home state made the issue of food an essential part of various social drives across the country and in every community at the local level.

Measures

- Food support through existing state government schemes for urban poor.
- Municipalities worked through the elected representatives at ward level (corporators) to distribute food supplies.
- Food supply to migrant grounds stranded at homes and between commutes.
- Contribution toward ration kits that included rice, dal, food powders, potatoes, etc.
- These kits were targeted in vulnerable populations and groups that were identified through existing CSR projects or communities that were part of the corporate's working base.
- Identification of population and collaborating with local support groups to engage in mass four-time meals.
- Supporting municipalities and CSR in implementation of their food distribution schemes and helping government and private sector to identify these socially vulnerable areas to further expand outreach and increase accessibility of food.

Access to Welfare: Institutional Restructuring

There are critical aspects in relation to agriculture and farm economy in the rural areas in order to understand the structural issues. In this, two areas, Minimum Support Price and Public Distribution System, are central to the agriculture and

food security challenges addressed above which in the past have been at the center to propose important recommendations for access to welfare. They are:

- Informal asymmetries at the micro-level of the governance process.
- Diversification in Minimum Support Price (Mahendra Dev, 2018, p. 23).
- Emphasis on cereals such as rice and wheat (Mahendra Dev, 2018, p. 24) creates issues of diversification within the Minimum Support Price policy.
- Need to understand micro-level systems and process to expand the scope of relevancy and reliance on PDS (Mahendra Dev, 2018, p. 23).
- Similarly, the role of direct cash transfers as compared to the PDS network of food.
- Ensuring stable export policies and mitigating the impact of fiscal and financial policies on structural reforms (Mahendra Dev, 2018, p. 24).
- These reforms include: “(a) price policy, (b) subsidies and investments, (c) land issues, (d) irrigation and water management, (e) research and extension, (f) credit, and (g) domestic market reforms and diversification” (Mahendra Dev, n.d.).
- Increase and growth in the role of private sector in agriculture; aligning agriculture sector with “new emerging agri-system” including rural businesses hubs (Mahendra Dev, 2018, p. 23).
- Impact of reforms on small and marginal farm groups and participation of these groups to access welfare.
- Gulati (2009) notes structural changes have happened at three levels: “diversification within agriculture sector, diversification from agriculture to allied activities like livestock and fisheries, and structural change from agriculture and allied to rural non-farm sector.”
- Development of WASH infrastructure in urban areas, especially in vulnerable and informal areas – and ensuring availability and access to essential WASH services such as water, soap for handwash, etc.
- Creation of community networks and mapping process for better availability, access, and distribution of essential commodities during health emergencies and distress situations.
- Connecting these reform areas and creating an inclusive and sustainable development framework.

These issues are interrelated to the inclusive governance practices and processes needed to avoid any overlapping or duplication of efforts and measures by stakeholders and be discussed through a common framework comprising of information and communication; community-led initiatives and structural integration are central features of an inclusive growth model. In the following table (Table 6), using this as the framework, the nature of work among government, private, and civil society is highlighted in each of the sectors.

Table 6 Nature of work among government, private, and civil society

Sector	Stakeholder	Intervention type	Nature of work
<i>Agriculture</i>	Government	ICT, structural	<p>Special aid package in terms of loans liquidity, reforms, expansion of funds in existing and new schemes</p> <p>Guidelines and recommendations for businesses, farmers, etc. toward processing and distribution of crops</p> <p>Guidelines and recommendations for upcoming agriculture season, and provide credit support for the same</p>
	Private (CSR)	ICT, community	<p>Information, technology, and market access to farmers for their produce</p> <p>Small credits and support to farm businesses</p> <p>Ongoing CSR projects in agriculture</p>
	NGO/CSO	ICT, community	<p>Help small farmers and out of job farm laborers in connecting with work sites</p> <p>Support physical connectivity measures in terms of access to markets, etc.</p> <p>Bridge information gaps, connecting demand-supply issues</p>
<i>Food security (rural)</i>	Government	Structural, community	<p>Special scheme for migrants ensuring them supply of food grains</p> <p>Support through PDS and other state government schemes</p>
	Private (CSR)	Community	Support through targeted food safety programs
	NGO/CSO	Community	Direct and collaboration with local authorities to ensure efficiency in food delivery system
<i>Employment</i>	Government	Structural	<p>Support through employment guarantee scheme Agriculture sector and essential services, etc.</p>
	Private (CSR)	Community	Provide livelihood support in communities where CSR is ongoing
	NGO/CSO	Structural, community	<p>Supporting GP representatives to process job cards for NREGS</p> <p>Support for GP representative in work related to GPDP</p>
<i>Health and WASH</i>	Government	Structural	<p>Policy planning and implementation</p> <p>Testing for new cases</p> <p>Operating and maintaining health and quarantine facilities</p>
	Private (CSR)	Community	<p>Supply of health, sanitation, and hygiene equipment to frontline workers across essential services and public</p> <p>Provide mobile testing machines</p>
	NGO/CSO	ICT, community	Supporting and getting directly involved in frontline work to provide essential health and sanitization items to vulnerable populations

(continued)

Table 6 (continued)

Sector	Stakeholder	Intervention type	Nature of work
<i>Food security (urban)</i>	Government	Structural	Direct support setting up food banks
	Private (CSR)	Community	Provide for kits in communities where corporate is active or associated with
	NGO/CSO	ICT, structural, community	Operate as food banks as well as supply essential services among vulnerable and weak socioeconomic populations

Concluding Remarks: Empowering Individuals and Capacity-Building to Address Exclusion and Pandemic-Induced Challenges

In India, empowerment and capacity-building strategy represent a multi-level approach to knowledge systems, spatial realities, and human capital while addressing poverty, livelihood needs, and employability. The nature of exclusion, defined by these conditions, push reforms and agendas linked to poverty alleviation and employment. These methods and steps are connected, broadly, to three interrelated conditions: (i) poverty alleviations and their links to vulnerabilities and deprivations such as hunger, malnutrition (SDG-2), and health and well-being (SDG-3); (ii) efforts to understand and capture socioeconomic vulnerabilities and poverty, and the relation of public policies for economic transformation and transparent reporting; and (iii) skilling and entrepreneurship initiatives created in cooperation with local bodies and in sync with the community needs (SDG-10).

Therefore, there arises a need to create tools to examine local challenges and to map the same at the district and state level. In order to do so, a response must have the following:

- Support from industry/corporate houses (through corporate social responsibility).
- Help strengthen start-ups and nongovernment initiatives.
- Create links with the local government system (functions and functionaries) to address community-level livelihood needs and employability concerns.

As immediate concerns, support, guidance, and information to local elected representatives in panchayats is the key challenge. This includes quickening the process of creating job cards under the employment guarantee scheme, and for doing this, NGOs and CSR programs can provide hand-holding better than government structures.

Abstract

The importance of water in our lives and for our sustenance cannot be stressed enough. It is a proven fact that the freshwater on our planet earth is only 2.5% of the total available water resources. Two thousand nineteen statistics on water scarcity state that 25% of the world population is facing water scarcity, making it one out of every five people. Grave and current issues like climate change, population explosion, urbanization blowing out of proportion in comparison to the services provided, and finally rapidly growing industrialization have made water into a scarce and valuable commodity. Growing demands on the use of water have resulted in a drop in its quality and capacity to self-cleanse.

Water is one of the most crucial and significant components of national development planning in the twenty-first century. Realizing the importance of water, the United Nations declared that safe water must be inexpensive and easy

S. K. Mahajan (✉)

A. P. Mahajan

Researcher and Author, based at Shimla, Shimla, Himachal Pradesh, India

to get for everyone by 2030. It has made this goal a part of the 17 sustainable development goals that must be achieved by 2030 by 193 member nations of the United Nations per their pledge (Population by Country, <https://www.worldometers.info/world-population/population-by-country/>, 2020). This is possible when every nation focuses on the legitimate and appropriate management of the limited water resource because it is crucial to ensure food security and resolve growing conflicts due to water scarcity. Hence, the water policy of any nation should recognize and adequately address the challenges faced by the world in the present and the future.

This challenge is getting tough day by day as the world population has touched the 7.7 billion people mark recently, and India's population has increased to 1.36 billion (Population by Country-2020). India has a 54% urban population of the total population in the world. There was a drastic increase in the international urban population, which went up to 54% from 30% (1950) in 2015. As per the estimates, it is expected to increase to 68% of the total world population's urban population by 2050. The issues mentioned earlier have been established to be the major cause in predicting an increase of 2.5 billion in urban population by 2050. Asia and Africa would be the leaders in the major problem of population crisis by 90% approximately (<https://www.un.org/development/desa/en/news/population/2018-revision-of-world-urbanization-prospects.html>. Retrieved 27 April 2020).

India has 4% share of the earth's land area which is highly disproportionate to its 17.71 population. The United Nations has reported that it is on the edge of an urban revolution based on the statistical prediction of its population to reach six billion by 2031. So, India will have about 40% of the urban population by 2031 (First Post) (Firstpost, Sunday December 1, 2019. Retrieved February 1, 2020, 2019).

The increase in urban population has created numerous problems for the Government and private organizations in dealing with the provisions of essential services to the people. The most severe challenge for urban planners is to tackle the impact of disasters. They have to increase and ultimately optimize disaster risk resilience.

Keywords

Smart water · Water policy · Management · Sustainable strategies

The smart cities concept has originated in the background of the increasing population and Disaster Risk Resilience. The term "Smart Cities" is trending around the globe. It is expected that smart cities should include smart energy, integration, public services, mobility, buildings, and water. This will lead to a high quality of life for the residents living in the cities. This has become the key focus area of the Government and the private sector because it is crucial for sustainable global growth.

Cities in India are made smart to keep up with the global changes and make them disaster resilient. The components of disaster resilience are (Jha et al., 2013):

1. **Infrastructure:** It refers to the vulnerability of buildings to hazards, critical infrastructure, including roads, health care facilities, etc. Its role is to develop the capacity of the community for response and recovery.
2. **Institutional Resilience:** The government and nongovernment organizations need to strengthen to adapt to the rapid changes happening in the environment.
3. **Economic Resilience** relates to the economic activities being carried out by the communities and their ability to function after a disaster.
4. **Social Resilience:** The demographic profile of the community, including sex, age, education, etc., can affect the role of the community's ability to deal with the effects of a disaster.

The components, as mentioned earlier, of disaster resilience, must precede risk mitigation to enhance capacity building. It has gained momentum, especially after the novel Corona Virus Disease (COVID 19) outbreak across the world. This pandemic has been recognized as a "notified disaster" by the Indian Government and led to invoking of the Disaster Management Act for the first time. The new Coronavirus has made the world rethink its strategies to upgrade the components of disaster resilience. Every nation, region, and city needs to identify and prioritize the most imperative needs like water, food, transport, healthcare services, etc.

The components will determine to what extent a city is a disaster resilience smart city. This study concentrates on the particular needs which are the most essential for survival after the disaster. For example, water is the most critical physiological need of disaster-stricken victims. Therefore, the water system in any city is considered a vital infrastructure.

Smart water refers to water and wastewater infrastructure with the help of effective management. Smart water is essentially filtered tap water as this process helps remove metals and contaminants. Smart water systems are more popularly known as intelligent water systems, but the water being produced by water distributors is called *smart water*. Whatever the nomenclature, one cannot deny its importance. The distributor of water adds minerals and additional vitamins to provide more nutritional value, which is usually not available from the tap water. According to the Nat Geographic Society, 1.2% of the 3% of the earth's water can be utilized as drinking water because the remaining is inaccessible, being trapped in the ground, glaciers, or ice caps.

Only about three percent of Earth's water is freshwater. Of that, only about 1.2% can be used as drinking water; the rest is locked up in glaciers, ice caps, and permafrost, or buried deep in the ground. Hence, it is crucial that the limited resources are not wasted, rather they must be efficiently utilized by implementing smart technologies like sensors to detect leakage, fortifying the water supply with necessary minerals so that there is mitigation in water borne diseases, especially, the vulnerable sections of the society.

Intelligent water systems through the use of new and innovative technologies have emerged as a valid solution to deal with the issue of providing affordable and safe drinking water to all as reported by The Water Environment Federation (WEF) along with the Water Environment and Reuse Foundation (WE&RF). Water-borne diseases are a major cause for the death of approximately 3.4 million people in least

developed economies. The death count due to this serious issue of unsafe drinking water was 1.16 million in 2020 ([The World Count, 2020](#)). The rate of death per time was one life every ten seconds which is a shocking statistics to comprehend.

India's average annual water availability has been estimated to be 1869 billion cubic meters (BCM). However, due to hydrological characteristics and topographical constraints, only 1123BCM (690 BCM is a form of surface water and about 433 BCM through replenishing able) for human consumption is available.

Per Capita Water Availability in India

Groundwater) can be utilized. It is evident from Table 1 that per capita water availability in India is shrinking at a rapid rate. The data available for per capita water availability relates to 2012, but one can imagine what a decade must have turned into ([Government of India, 2012](#)). Some issues highlighted by the Government of India are:

1. Huge areas of India are burdened with the availability of water. Population growth, urbanization, and changing lifestyles have resulted in water scarcity.
2. Water resources are not being managed efficiently or judiciously leading to a critical standpoint in many parts of India.
3. India has a high differential in water availability. Climate change has deepened the water crisis and water-related disasters.
4. Salinity intrusion because of the increase in sea level due to climate change is another concern.
5. Skewed water availability and unreliable water supply system lead to social unrest in some parts of the country.
6. Natural water bodies and drainage channels are being infringed upon, leading to the groundwater recharge zone blockage.

Apart from these concerns, there are other areas in which public agencies need to take charge of the water-related issues. In the end, there is a massive gap between a holistic and inter-disciplinary approach to this problem. First, though, International agencies (UNICEF, WHO, UNESCO, UNEO, etc.) focus their attention on the issues. The National agencies have also started showing the urgency to tackle the concerns.

Table 1 Per Capita Water Availability in India

Year	Population (in millions)	Per capita water availability(mm ³)
1951	361	5177
2001	1027	1820
2025	1394	1341
2050	1640	1140

Source: Government of India (2011), *Strategic Plan for Ministry of Water Resources*, Ministry of Water Resources, New Delhi, p. 5

For example, National Water Mission has developed new initiatives, which are state-specific plans (<http://nwm.gov.in/?q=new-initiatives>). The new initiatives carried out by the Ministry of Jal Shakti under the National Water Mission are:

1. State-Specific Action Plan

- (a) The National Water Mission has developed *State-Specific Action Plan* for the water sector covering the following aspects:
- All states in India must be evaluated individually regarding the status of water resources, institutional framework, inter-state issues, and the like.
 - Identify critical issues/problem areas and suggest probable solutions under the given circumstances.
 - Preparation of detailed project reports for problem areas identified by the National Water Mission and carried by the states/union territories.
- (b) Determination of a possible way out of the current crisis by analyzing the pros and cons.
- (c) Formulation of an action plan in detail for each activity decided upon in the NWM to be executed by the state/union territory.

2. Improving Water Use Efficiency (WUE) in Irrigation Sector Base Line Studies

Baseline studies are in progress to assess the present position. Five major projects have been initiated in different parts of the country.

Goals of the National Water Mission

The following goals have been determined based on the initiatives:

Source: Retrieved on 29-10-2022 at <http://nwm.gov.in>, National Water Mission, Department of Water Resources, RD and GR.

It can be observed that an unusual increase in the urban population has seen enormous pressure on the existing infrastructure. This has forced the Government to rethink its strategies to develop infrastructural facilities to improve living standards for the people, including the migrants living in the urban areas.

This is possible only by comprehensive physical and institutional infrastructure development. Therefore, the Government of India introduced the concept of Smart Cities in the recent past. The Smart Cities Mission emphasized improving the quality of life of people by accrediting local area development. The aim is to provide equitable opportunities and access to basic infrastructure for its residents.

No Water Management in Smart City Features

It is difficult to understand the reason for the exclusion of “water” from the features of smart cities.

The features of comprehensive development in Smart Cities are (Smart Cities Mission <http://smartcities.gov.in/content/innerpage/smart-city-features.php>):

1. Promotion of mixed land use in the development of unplanned areas to achieve efficiency in land use
2. Expansion of housing projects
3. Building walkable residential areas
4. Preservation and development of open areas, for example, parks and playgrounds;
5. Promotion of transport options like public transport
6. Promoting efficient and easy digital services to make governance more citizen-friendly
7. Encourage local culture
8. Implementation of smart solutions in areas of infrastructure and services

The latest report by the Bureau of Indian standards (November 19, 2020) shows that Delhi is at the bottom, with 11 out 11 samples failing on 19 parameters laid down by it. All major cities did not comply with the requirements of the standards. However, the Ministry of Water Resources, Government of India, issued the revised guidelines for water quality in 2015, but there have been no substantial or practical solutions.

This chapter is about the status of Disaster Resilience Smart Cities with particular reference to water. Still, in the features of smart cities prescribed by the Government of India, there is no reference to water or disaster resilience. Nongovernmental organizations and citizens need to pressurize the Government of India through legal proceedings and proactive awareness campaigns or protests to add these two features to its prescribed plan for smart cities to bring sustainable development to the nation at present as well as our future generations.

The Smart water City should integrate urban planning and water management to increase climate resilience. Smart water Cities are a crucial component to enhance the quality of urban life. Improvement in the quality of life has been receiving attention from the Government, private sector, and academicians, but there has been no result. Thus, providing opportunities for the considerable investment to develop and recreate urban infrastructure by agencies is involved in this mission.

Steps toward creating water Smart Cities have been explained below:

Steps Toward Water Smart Cities

1. Identify Challenges and Opportunities

The first challenge toward building water Smart Cities is to identify the livability needs of the people and the existing water system prevalent in the city. Then these opportunities can be related to the needs of goals of the area.

2. Define Water Smart City Vision

Every city needs to set up a vision of “when to become a Smart water City” – keeping in mind the challenges and opportunities available in the city. The vision needs to be shared with the stakeholders, and the timeline to achieve online.

3. Explore Cocreation Opportunities

Every city has its natural water system and living conditions peculiar to it. Therefore, all plans and actions need to focus on the requirements to make the city water smart. An infrastructure project in water management also needs to be initiated by linking it to climate adaptation goals.

4. Codesign Solutions

It refers to identifying possible optimal measures to reach the “cities” aspiration, especially water. This can be done by integrating the stakeholders (Government, citizens, research organizations, and investors).

5. Define Business Case

Each possible measure has its advantages and disadvantages. These should be weighed, keeping in mind the break even of possible actions. So a balanced approach needs to be identified before executing the potential measure.

6. Implement and Evaluate

These are the continuous measures for the Smart water Cities. Periodic evaluation of the measurements should be carried out according to the needs and requirements of the cities by monitoring the database (Fig. 1).

Summing up, it can be observed that the steps toward the water Smart Cities should also include:

- Water distribution network
- Maintenance and reliability of distribution network
- Recycle and reuse water

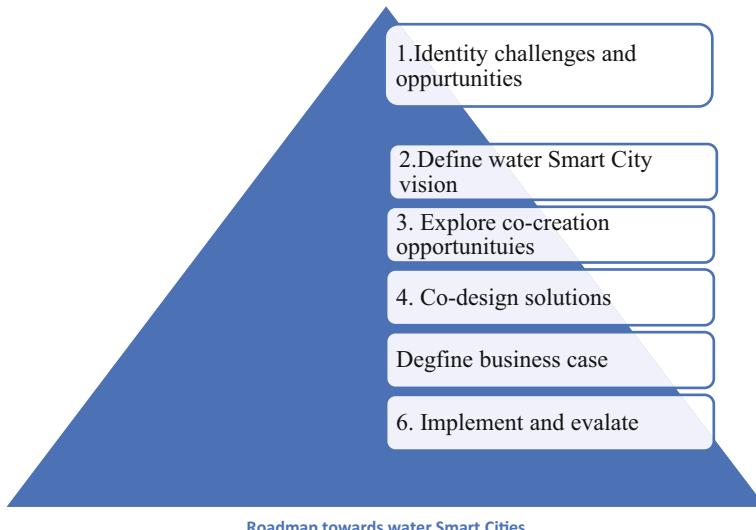

Fig. 1 Roadmap toward water Smart Cities. (Source: Tim Van Henthin et al. (2016), Towards water Smart Cities, Wageningen Environmental Research, Alterra, P.5)

- Developing management information system and database to take care of demand-side management
-

Success Stories

A Water-Secure Village

Mewat includes the Mewat district of Haryana and parts of Alwar, Bharatpur, and Dholpur districts of Rajasthan. Groundwater is the primary source of water, which is saline, making it unfit for human consumption.

With the help of SM Foundation, an NGO of Gurgaon, the villagers of Patkhori village practiced conservation to resolve the problem of water shortage.

Saving India's Lifeline: Why Rivers Need Trees

According to Sadhguru, “We are destroying the soil and water resources at such a rate that in another fifteen to twenty years time, we will not be able to feed these people and quench their thirst”. This can be done through more tree planting through the Project Green Hands. Individuals should be encouraged to plant trees along the banks of rivers and water bodies.

Conclusion

Water is included as a subject in the state List (List2) of the seventh Schedule of the Constitution of India. States have been entrusted with all water-related activities: water supplies, irrigation and canals, drainage and embankments, water storage, and water power subject to the provisions of entry 56 List 1. The Indian Constitution lays down the laws regarding development of inter-state and river valleys by the Union Government. However, it has been observed that water disputes between the states have been on the rise in the recent past.

In India, most policies, plans, and projects have immense readability but lack governance, i.e., their execution, implementation, and monitoring. The national water Resources Council (as suggested by M.M. Punchi Commission on Centre-State Relations). National Water Policy should evolve the consensus on water-related issues through the National Water Resources Council. In the end, it is prudent to say that all is not gloomy. India has a few success stories that explain that we all can collectively fight the battle against water scarcity in the years to come.

Abstract

Manipur is highly vulnerable to natural disasters such as earthquakes, landslides, floods, and drought. Manipur faces vulnerability to earthquakes as the state falls in zone V. Ima Market or Nupi Keithel, a unique women's market in Asia, was severely hit by the earthquake in 2016, causing extensive damage and displacing thousands of women vendors. This study examines community resilience in the context of the chronic flood in Imphal city. Data revealed Manipur has a history of floods which began in 1916 and continued in the following years, i.e., 1929, 1941, 1953, 1965, 1966, 1989, 1992, 1997, 1998, 1999, 2001, 2015, 2017, 2019, and 2020. Imphal city is the most flood-affected area and is connected to the incessant heavy rainfall in the upper catchment areas, constituting about 70% of the total catchment areas. The poor urban drainage system, encroachment of river banks, and numerous vulnerable points of the embankment of major rivers are causing floods in Imphal city. Improving roads in Imphal city without improving the urban drainage system worsens the situation. A vital community resilience needs to increase the roles of states, local communities, and stakeholders in

rescuing, evacuating, distributing relief materials, and preventing the epidemic outbreak.

Keywords

Resilience · Breach · Water · Drainage · Flood · Catchment

Introduction

Manipur is located in the northeastern part of the country bordering Myanmar in the south, Nagaland in the north, Mizoram in the south-west, and Assam in the west. It has a geographical area of 22,327 sq. km, constituting 0.7% of the total land surface of India. Manipur exhibits unity in diversity, as several ethnic communities have coexisted, exhibiting their customary laws, religions, identities, and cultures. There are 16 districts. viz., (i) Imphal East, (ii) Imphal West, (iii) Bishnupur, (iv) Jiribam, (v) Thoubal, (vi) Kakching, (vii) Senapati, (viii) Kangpokpi, (ix) Tamenglong, (x) Noney, (xi) Churachandpur, (xii) Pherzawl, (xiii) Chandel, (xiv) Tengnoupal, (xv) Utkhrul, and (xvi) Kamjong. Imphal city is situated in the heart of the Imphal West district. Report (Government of Manipur, 2021) pointed out that the proportion of the urban population to its district population was highest in Imphal West, with 62.33 percent among valley districts. Imphal valley is drained by two rivers, (i) Imphal river and its tributaries and (ii) Nambul river. Imphal river rises in the highlands to the western part of Kangpokpi hills which lie in the northern part of Imphal valley. The river is joined by many tributaries like the Sekmai river, the Thoubal river, the Kongba river, and the Iril river. The Imphal river does not fall in the Loktak; it flows in the eastern part of the lake. The Nambul is another vital river of Manipur that drains the Imphal valley. It rises in the Kangchup hills in the western part of the valley. The river passes through the heart of Imphal city and follows a course in the west of Imphal river till it falls into the Loktak. Breach of embankment on Imphal river and the Nambul river causes chronic flood in Imphal city during the rainy season.

History of Flood

Over the last few years, the floods in Manipur have caused extensive damage to properties and essential infrastructures (such as bridges, communication, and power). There was a flood in 1916 that affected significant areas in the Imphal East district on the east side of the Imphal river (such as Wangkhei, Khurai, Kongba, Porompat, Bamon Leikai, and Soibam Leikai). After this, Manipur experienced a flood in 1929 that lasted 3 days, mainly in the valley areas. The state also recorded a flood in 1941 affecting some areas on the western side of the Imphal river, particularly the Yaiskul area, due to a breach of the Imphal river embankment at

Moirangkhom. Flood again struck the valley areas of Manipur in October 1953. Manipur experienced a moderate type of flood in 1965. Following this, a severe flood hit the state twice in 1966 (June–July and October), affecting places like Hiyanglam, Sugnu, Arong, Nongmaikhong, Wangoo, and Tanjeng. Breach of embankment took place at 60 places. Manipur witnessed a flood from July to August in 1989 where the flood severely affected Imphal valley. Altogether 361 localities were inundated due to a breach of embankment in 40 places. The flood had affected 7 lakh people, and 97,500 hectares of paddy fields were damaged. More than 40,000 houses and 41,000 domestic animals were damaged. Incessant rainfall in the upper catchment area of important rivers in Manipur valley caused a flood in October 1992. Manipur awoke to find its valley flooded in September 1997. All the rivers flowing through the Manipur valley increased their water flow rapidly and breached embankments at four different places of Nambul river, two places of Wangjing river, one place of Merakhong river, two places of Imphal river, two places of Thongaorok river, one place of Khujairok river, and one place of Khabi river. More than 4000 houses were damaged. Heavy and incessant rainfall breached many embankments and caused inundation in several parts of Imphal, such as Iroisemba, Lamding, Nashikhong, and Lamding Laishram Leikai adjoining areas, in 1998. Manipur saw severe floods in September 1999 due to incessant rainfall from August 24 till September 3, 1999. The flood damaged more than 7000 houses and 15,000 hectares of paddy fields. It was followed by a severe flood in 2000, causing inundation in many parts of valley areas in Manipur. The flood damaged 2400 houses and 7800 hectares of paddy fields. Incessant rainfall breached the river embankment, and water overflowed through (the embankment), inundating several parts of Imphal city in June and July 2001. Breaching of the embankment also caused a flood in Kongkham, Sabal Leikai, Maibam, and Naorem. Chandranadi river, a tributary of the Nambul river, overflowed to the southern part and inundated cultivated lands of Chajing, Haoreibi, and Karam. Another flood had hit Manipur in August 2002. Besides this, Manipur experienced a flood in 2017, inundating several parts of the valley areas. Districts affected by this flood were Imphal East, Imphal West, Thoubal, Bishnupur, and Kakching. Flood hit Manipur in 2018, claiming six lives in the districts of Kakching, Thoubal, Bishnupur, Imphal West, and Imphal East. Manipur recorded a severe flood in 2019, affecting schools, houses, community halls, temples, playgrounds, clubs, and crematoriums along Imphal river banks. Extensive agricultural lands in many valley areas such as Yumnam Khunou, Sambei, Tangkham, Khundrakpam, and Pangei, with some villages located on the western side of Sajiva Central Jail, were flooded. A flood occurred in 2019, displacing more than 70 families in the Jiribam district of Manipur. Jiri river, which runs along the border with Assam state, breached its embankment on October 27, 2019, and inundated several areas. Manipur witnessed a flood in 2020 due to incessant rainfall for a few days triggering landslides in several parts of Manipur and losing connectivity with some areas of the state. Noney and Tamenglong districts were severely affected by the landslides. The intensity of floods in Manipur ranged between moderate and severe magnitude.

Seasonal Flood and Risk

Statistical data on seasonal hazards and risk assessments are presented in Tables 1 and 2. As shown in Table 1, flash floods and heavy rainfall tend to occur from June to August, while hailstorms and thunderstorms tend to occur from March to May. From Table 2, it can be seen that vulnerable areas include infrastructure, crops, houses, public property, livestock, socioeconomic life, health, education, old age, children under 5 years, and sick people.

Table 1 Seasonal hazard analysis

Imphal City

Khwairamband Bazar is located in the center of Imphal city and is popularly known for its unique women's market. There are three Ima Keithels (Ima means mother and Keithel means market) or Nupi Keithel (Nupi means Woman). They are (i) Leimarel Sidabi Ima Keithel (1300 Women), (ii) Emoinu Ema Keithel (700 Women), and (iii) Phouoibi Ima Keithel (1000). They sell religious goods, vegetables, fruits, fish, spices, utensils, handloom, and handicraft items. These markets have become tourist hotspots in Manipur. Imphal city has been expanding fast, converting many wetlands and water bodies into dwelling units (Zutshi & Verma, 2017). In this process of expansion, even the flood spill channels have been encroached upon, and residential colonies have come up closer to water bodies. These areas were the worst affected during the floods of July–August 2015. Floodwaters followed the natural path and inundated whatever came in their way. The present study selected Imphal city and concentrated on a few selected sites such as (i) Yaiskul, (ii) Sagolband, (iii) Uripok, (iv) Nongmeibung, (v) Kakwa, (vi) Kwakeithel, (vii) Tera, (viii) Wangkhei, (ix) Kongba, (x) Khuman Lampak Sports Complex or Namdunlong Village, and (xi) Naoremthong. A map of Imphal city is shown in Fig. 1. It may be particularly mentioned here that the Nambul river, which passes through the center of Imphal city, serves as drainage discharging water drained from its tributaries and surrounding areas. During the incessant rainfall, the river cannot contain the speedy flow of water draining from its tributaries and urban drainage, causing frequent floods in the city. Apart from that, the distributaries of the Nambul river are not functioning properly.

Socioeconomic Indicators

Table 3 presents data on the socioeconomic indicators of Manipur. It may be observed from the table that GSDP of Manipur state at constant prices in (2019–2020) accounted for 20,743 crores. Per capita income of Manipur at constant (2011–2012) was estimated at Rs. 54,119 in 2019–2020. As per Census India (2011), the population of Manipur was estimated at 28.56 lakhs with a decadal growth of 25%.

Data also shows that the work participation rate was estimated at 45.6%. While the literacy rate accounted for 77%, the sex ratio recorded for 985 per 1000 males. There are 2582 villages; out of these 2205 villages have been electrified. While state beneficiaries under AAY accounted for 2,00,500, state beneficiaries under PHH recorded 21,38,935. The communication network of any state is identified by examining its establishment of post offices, radio stations, TV networks, and provision of Internet services. It may also be seen from the table that there are 50 post offices, including branch offices in Manipur state, 3 radio channels, and 1 TV station. Apart from All India Radio and TV (Doordashan, DD Imphal), various services of local television networks are mushrooming in the state. It may be said that the local television network is growing fast, and it helps disseminate knowledge and

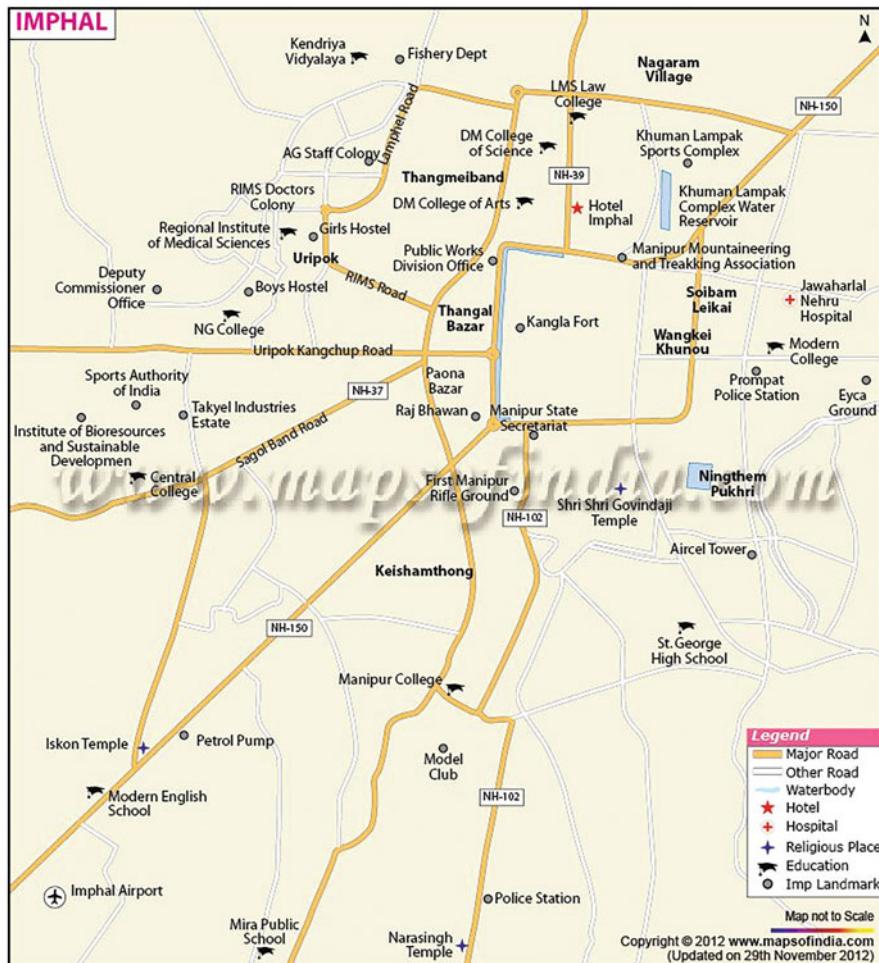

Fig. 1 Map of Imphal city. Source: <https://www.mapsofindia.com/maps/manipur/imphal.htm>

information to the public. As regards to government's healthcare facilities, there are 553 hospitals/dispensaries.

Community Resilience

Community resilience is the ability of countries, communities, and households to manage change by maintaining or transforming living standards in the face of shocks or stresses – such as earthquakes, drought, or violent conflict – without compromising their long-term prospects (DFID, 2011). According to OECD (2013), disaster resilience is part of the broader concept of *resilience* – “the ability of individuals,

Table 3 Socioeconomic indicators of Manipur

communities and states and their institutions to absorb and recover from shocks, whilst positively adapting and transforming their structures and means for living in the face of long-term changes and uncertainty.” Through the Global Facility for Disaster Reduction and Recovery (GFDRR), the World Bank highlighted five core areas for building disaster resilience. They are (1) risk assessments and risk communication; (2) structural and nonstructural measures, e.g., infrastructure, land-use planning, policies, and regulation; (3) preparedness (early warning systems; support of emergency measures; contingency planning); (4) financial protection (assessing and reducing contingent liabilities; budget appropriation and execution; ex ante and ex post financing instruments); and (5) resilient reconstruction (resilient recovery and reconstruction policies; ex ante design of institutional structures). The concept of resilience is highly relevant and applicable in the context of chronic flood in the

Imphal city. Building disaster resilience in terms of structural and nonstructural measures, financial protection, risk assessment, and emergency support system is strongly needed in Manipur.

Flood in Imphal City

Manipur drains its water from the northern sides toward the southern direction of its boundary. However, there has been a significant change in the natural setting of Manipur's river system over the past decades resulting in a frequent flood in Imphal city. For instance, tributaries such as streams and rivulets that feed the Nambul river have been significantly narrowed down and shallowed down due to human encroachment. The major outlet or distributary channel of the Nambul river called Waishel Maril has also been significantly contracted and shallow. Therefore, this channel cannot carry its water flow properly toward its destination, i.e., Loktak lake. The study also observes one phenomenon that the water level of rivers flowing through the Imphal valley significantly increases when there is incessant rainfall in the upper catchment areas. This level will flow higher than the streams that feed the river. During this peak level of river water, the normal flow of water that is being drained through the streams cannot enter the river flow. Instead, the water flows back and inundates a large part of Imphal areas. Once the water level drops in the river, the water will drain and enter the river. Then, the flood will recede automatically.

Flood in Manipur valley is primarily due to heavy rainfall in the upper catchment areas ([Manipur State Disaster Management Plan, 2018](#)). The intensity of rainfalls is higher in the hilly region than in the plain. While the hills surrounding the valley constituted 70% of the total catchment area, the valley area contributed 30% only. Thus, the valley in Manipur has a large upper catchment area where rainfall usually is high. These reasonable amounts of rainfall feed many streams and rivers, which finally drain through the valley. In the hills, steep slopes occupy the central portion. Besides, degraded land areas, which occupy 1545 km, constituted 24% of the total catchment area and 35% of the hilly region, enhancing more erosion and runoff. There are many vulnerable points along the riverbanks of the major rivers of Manipur valley. In these areas, erosion, sliding, and slumping of the banks are common, causing a breach of riverbanks to these points during the rainy season. Proper maintenance of these riverbanks is necessary, and retaining walls are to be constructed. The plantation of trees will help to some extent. A study by Singh, S. ([2015](#)) found that the causes of floods in Imphal valley include poor urban drainage, deforestation, and other factors including breaching of river banks, improper damming, sediment pollution, siltation, shallowing of river beds and lakes, heavy precipitation in the catchment area, changing land-use pattern, and vanishing of traditional recharging structures and water bodies. Earlier, the various lakes of Manipur, mostly located in the southern part of the valley, served as effective reservoirs of excess runoff. Most of the lakes are severely degraded in

quality to the extent of complete disappearance resulting in severe curtailment of their water-holding capacities. The magnitude of a natural flood produced by rain is related to the intensity and duration of rain over the catchment area, the rate at which water flows across the land surface toward the river channel, and the flow of water through the ground to drainage systems. Flash floods can occur in urban areas due to poor drainage facilities. The rate at which water enters river channels depends particularly on vegetation cover. Large floods occur where there is little vegetation and many soils and paved surface areas are impervious to water. Such floods are called downstream floods because the effect of flooding increases progressively downstream.

Low-lying areas in various localities of Imphal were flooded as the Nambul river overflowed, and several farmlands were also inundated (*Hindustan Times*, 2017). A portion of the Imphal riverbank collapsed in the Imphal East district, creating panic among the people. With more than 300 households affected, many fled their homes to seek refuge at voluntary and government-provided temporary relief camps. Several low-lying areas in the capital, such as Kwakeithel, Wangkhei, Sagolband, and Kakwa, had been flooded due to a blocked drainage system (*The Times of India*, 2018). The water level of the Imphal and Kongba rivers that flow in the districts of Imphal West and East was increasing gradually. The water level of the Nambul river overflowed in some parts of Uriopok in Imphal West district due to heavy rain in the catchment areas, and it receded (*The Times of India*, 2017). The Manipur government declared a holiday for all government offices and educational institutions, including private sectors under the government, as the flood hit most parts of Imphal city (*The Sangai Express*, 2019). The sustained rains had overflowed most of the major rivers that run through Imphal city, particularly the Imphal and Nambul rivers. The Imphal river overflowed and breached its bank, submerging large residential areas, including VIP colonies housing the chief secretary of Manipur, DGP Manipur, and other top bureaucrats, under the Imphal East district. The district came to a grinding halt with overflowing water flooding the streets of its commercial hub. The power supply in most parts of the districts affected by the flood was cut off as safety measures. The radio service of All India Radio (AIR) Imphal was also suspended as a flood hit the office complex. The nonstop downpour had raised the water levels at Imphal and Nambul rivers and reached flood levels. The strong current of the water washed away significant parts of the bridge under construction over the Irl river at Sawombung. In some Khurai areas, the water had even breached the river banks and flooded the surrounding homes. Water from the Imphal river overflowed at Thumbothong and Checkon sides (*The Sangai Express*, 2019). Flooding in the cities and towns is caused by increasing incidence of heavy rainfall in a short period of time, indiscriminate encroachment of waterways, inadequate capacity of drains, and lack of maintenance of the drainage infrastructure (Government of India, 2008).

In sum, a number of factors contribute to frequent flooding in Imphal city, including the vulnerability of river banks (often breached), lack of vegetation, encroachment, deteriorating drainage systems, and deforestation in the upper catchments. The state needs to be prepared for disasters in advance.

Resilience and Community Response

There is a lack of community awareness on responsiveness, preparedness, mitigation, and recovery during a disaster in Manipur (Singh, 2018). The local community lacked training about their shelter, rehabilitation, relief entitlements, schemes, and legal access in times of disaster. The main factors causing floods in specific places of Imphal cities like Sagolband, Uriopok, and Nongmeibung are lack of proper drainage system, deforestation in catchment areas, breach of the river embankment, improper damming, changing land-use pattern, and vanishing of traditional recharging structure and water bodies like ponds and tanks due to urbanization. There are also some effects of floods in Imphal city. People are facing many problems during and after the flood. Flood damages houses and properties, creating transportation problems, electricity problems, disturbance in education, reduction in the economy, and spreading waterborne diseases. During a flood, local club volunteers arranged and opened a relief camp at a community hall or school for the safety of affected people and distributed food.

Furthermore, their MLA, social workers visited the affected areas and extended their hands, providing essential commodities like drinking water, PDS items, and relief materials. In Uriopok, Yaiskul, and Tera, flood is mainly due to the failure of the drainage system in that area. When there is heavy rainfall, flood condition worsens due to the overflowing of river water. The bad condition of drainage worsens floods caused by river overflow. Local clubs initiated cleaning up of drainage, and now flash flood condition has improved. Due to the construction of the embankment of Nambul river, a breach of the embankment has not occurred. Concerned departments have taken specific measures like constructing river embankments and retaining walls. When there is a breaching of an embankment, local clubs and government agencies work together for restoration work. During a flood, local clubs help in the evacuation and mitigation process. The government has started renovating the drains, which will reduce the severity of floods in the locality. Local clubs help people in evacuating the affected people to a safer zone.

The main rivers draining Imphal West plain are the Imphal river, Nambul river, and their tributaries (District Disaster Management Plan, 2019–2020). Nambul river is made up of a number of small streams on its upper course. This river passes through the Imphal municipality area dividing its area into almost two halves. This river serves as the main discharging drainage of the Imphal Bazar area and its surroundings. During the rainy season, swift flowing of water directed to it from its tributaries cannot be contained in it. As a result, the breaking of its river bunds causing waterlogging in the low-lying area is a regular feature. In Manipur, various lakes located in the southern part of the valley act as effective excess runoff reservoirs. However, due to the degrading quality of the lakes, their water-holding capacities have been reduced to a great extent. It has led to the flooding of the low-lying areas, which causes various problems such as destruction of houses and properties, loss of lives, water and electricity problems, spreading of waterborne diseases, damage to farms and pisciculture, a severe reduction in the economy, and many more. In Nongmeibung, people have experienced floods every year, and the

worst affected year was 2017, when it was flooded for around 2 months. During that period, people faced many problems, such as food shortages and drinking water. Affected people from the locality even had to leave their homes and stay in the community relief centers as their houses were all flooded, while some people also went to stay at their relatives' place till the water level came down. As the water became stagnant for a long period, it caused many diseases. The locality club played a vital role in tackling the problems being faced by the locality. They helped distribute relief items supplied by the government, such as food and drinking water. They arranged a relief center for those people whose houses were all flooded and who had no place to stay. As the water levels had not gone down for a long period, the people of the locality tried to pump out the water from the flooded area to help dry out the water faster. In Kongba, people have experienced floods every year during the monsoon season. The main reason for the flood in this area is the overflow of the Kongba river. They faced many challenges during that period. For instance, due to a shortage of food supply, they had to use small boats to go out of their house to buy essential commodities. People of the locality had to make new drains so that the water would not be stagnant in a particular area and help dry out the water faster. The councilor of that area also helped people of the flooded area by distributing food items and other dry materials. They also organized medical relief camps for the affected people after the flood, as the disaster had both acute and chronic effects on the physical and mental health of the affected population. In the Wangkhei area, several low-lying areas are flooded annually due to improper drainage systems. After constructing the sericulture office at Sangaipat, the nearby areas are constantly flooded as there is no proper channel for the drainage system. As a result, many families suffered from floods every year at which they had to leave their houses and stay at the community hall. Several families in Wangkhei suffer from floods every year due to an overflow of ponds and drains. Before constructing the sericulture office at Sangaipat, the water flowed through Sangaipat and went off to the Bamon Leikai area through a proper drainage channel. However, after the construction of the sericulture office, the water from ponds and drains was stuck in low-lying areas. So, people have to pump out water by themselves as there is no proper drainage system. The primary causes of floods in Manipur valley are heavy runoff and a lack of a proper drainage system. In the past few years, Manipur faced multiple events of the flood, where it had occurred five times in the year 2017. It has dramatically affected the socioeconomic condition of the state to a great extent. The mitigation and management of flood events are essential to reduce the impacts of floods. Severe flood around the Khuman Lampak Stadium Road occurred in 1989. People lost so much livestock as they were drowned and carried away by the water toward Kangla and the bazaar area. People set up a big relief camp on the main road near the Stadium Road during the flood because of a higher ground level just next to the flood area. The neighboring localities were unable to provide relief and support except for helping in simple tasks like shifting heavy objects for houses and families living closest to them or those related to them. Church leaders play a significant role during flood disasters. The Chingmeirong Catholic Church was the first to provide relief in the form of food. Even after people got rehabilitated back to their homes, they went

to the Manipur Baptist Convention (MBC) church campus to get a vaccination, and people got vegetables and rice as a relief. During the flood, the army also helped in relief works.

Conclusion

Imphal city is the most flood-affected area and is connected to the incessant heavy rainfall in the upper catchment areas, constituting about 70% of the total catchment areas. It is also linked with the poor urban drainage system, encroachment of river banks violating the Manipur Flood Plain Zoning Act 1978, and numerous vulnerable points of the embankment of major rivers. Deforestation in the surrounding hills that leads to denudation in upper catchment areas with a continuous shrinking of traditional water bodies and lakes exacerbated the flood in the Imphal valley. Particular mention may be made of the drainage network system in the Imphal city, which has not been doing its proper work and instead created stinking spots in the Khwairamband market. Continuous improvement of roads in Imphal city is not accompanied by improving the urban drainage system. The National Policy on Flood Control (1954) is ineffective in dealing with flood embankments, drainage channels, and town protection works. A vital community resilience needs to increase the roles of local communities, NGOs, urban local bodies, Panchayati Raj Institutions, autonomous district councils, civil society organizations, religious leaders, and stakeholders in checking floods, rescuing, evacuating, distributing relief materials, and preventing the epidemic outbreak. Training has been found to be the most effective tool for reducing vulnerabilities (Zutshi & Verma, 2017). Plantation of fast-growing trees in the upper catchment areas to reduce soil loss and encouraging terrace cultivation on the slope of the hill are also recommended. Finally, it would be very helpful if proper action could be taken up for the deepening of these lake beds.

Abstract

The frequency and severity of natural disasters have risen worldwide in recent times, causing loss of lives and property and migration of vulnerable populations. In 2019, India recorded the highest disaster displacements in South Asia. Kolkata, the capital of West Bengal, a city situated in the Indo-Gangetic plain, is ranked the fourth most vulnerable among 11 major coastal cities in Asia threatened by rising sea levels. To add to its woes, the world's largest mangrove forest, the Sundarbans, which has historically been its cyclone shield, faces submergence due to rapidly rising sea levels, with acres of crops being destroyed by saline water. The effects of the depletion of the mangrove forest have been manifested from the disastrous consequences of Cyclone Amphan (May 2020) and Cyclone Yaas (May 2021) in southern West Bengal. The island of Ghoramara has been reduced to half its size. Following Cyclone Yaas, islands of Ghoramara and Mousuni have been evacuated by the government. Climate refugees systematically displaced from the outer islands of Sundarbans have relocated to Sagar Island and are gradually pouring into Kolkata, looking for alternative

accommodation. The lack of national or state policy and a general apathy of the government regarding strategic rehabilitation of climate migrants are proving to be burdensome for Kolkata, a city already bursting at its seams. This paper will evaluate the factors behind the disaster displacement that Kolkata is expected to face soon and propose strategies to mitigate the issues arising from such unchecked migration from the Sundarbans.

Climate change · Disaster · Kolkata · Sundarbans · Migration

Introduction

Displacement and migration of population because of climate change and natural disasters are major challenges humanity faces today. Various factors have contributed to worldwide climate change, which may be broadly divided into two categories: slow global warming over a period resulting from natural causes and the other being acceleration thereof because of various factors triggered by humankind and its activities. The 2022 Intergovernmental Panel on Climate Change has warned that the earth will hit the critical warming of 1.5°C within two decades (IPCC, 2022), human activities being the unequivocal contributor to such irreversible changes, and that extreme climatic events shall become more frequent. Whatever be the root cause, global warming has manifested itself in the meltdown of polar ice belts and rising sea levels, one of the disastrous effects thereof being the submergence of islands and coastal belts, which are typically low-lying in nature.

The incidents of submergence have translated into forced or compelled migration of the local population of such islands and coastal areas, such displacement being either temporary or permanent. Such migrations have been either in response to extreme weather events like cyclones, floods, etc. or climate variations resulting from longer-term changes, like rising sea levels, etc. This apart, migrations may also stem from the scarcity of resources or increased conflict among the population because of factors directly attributable to climate change.

Climate migration is not new or endemic to the Sundarbans, the deltaic region in the southern part of West Bengal and Bangladesh. A study by Norman Myers, a British environmentalist, suggests that going by the current trends, there may be as many as 250 million climate refugees worldwide by 2050 (Myers, 1993). Lack of adequate water has compelled the government in China to mandate a series of relocations since 1983 in Xihaiyu, Ningxia. The mass migration in Minqin, Gansu, has seen the coinage of a new term, *shengtai yimin*, or ecological migrants (Muscolino, 2011). The increasingly alarming fear of flooding caused by a rise of temperature to 3.4° has caused four Alaskan villages to require immediate evacuation (USGAO, 2009). Louisiana has seen the loss of more than 2000 square miles of its coast, translating into the first migration of an entire community of the Biloxi-Chitimacha-Choctaw First Nation due to saltwater intrusion (Davenport &

Robertson, 2016). The Balkan flooding has caused considerable migration of people from Bosnia and Herzegovina to other countries in Europe (Monella & Carbone, 2020). In India too, eminent environmentalist Ramachandra Guha coined the term “ecological refugee” to describe the class of people displaced by reason of environmental factors, playing their role in the cauldron of conflicts that developmental policies after 1948 engendered (Gadgil & Guha, 1995). While certain developed countries have continued to deny the factum of climate change till very recently, its reality is being perceived every day and in every corner of the earth.

The United Nations Office for Disaster Risk Reduction defines “disaster” as “a serious disruption of the functioning of a community or a society at any scale due to hazardous events interacting with conditions of exposure, vulnerability, and capacity, leading to one or more of the following: human, material, economic and environmental losses, and impacts” (UNISDR, 2009). The overarching effect of climate change has brought increasingly numerous and severe localized instances of disaster such as floods, inundation, cyclones, sandstorms, sea-level rise, blizzards, snowstorms, etc. Still, it has also emerged as the single most pervasive disaster incident. The migration of masses as a direct consequence of the cumulative effect of localized disaster and climate change is no less a disaster that humankind will have to grapple with within the coming days (Sherbinin, 2020).

Climate Refugees, Disaster Migration: Where Are We Headed?

The issue of equity is crucial; Climate affects us all but does not equally affect us. (Ban Ki-moon, UN Secretary-General)

“Climate refugees” refer to the large-scale cross-border migration of people wholly or partly caused by weather-related adverse conditions in their homelands (UNGA, 2018). A 2019 report by Internal Displacement Monitoring Centre shockingly reveals that India topped the list of countries with the newest displacements because of climate change disasters in 2019, ahead of the Philippines, Bangladesh, China, and the United States (IDMC, 2019).

Disaster-driven migration may be internal, that is, within the boundaries of a country, or external, that is, to other countries. While there is scope for internal migration to be governed by the laws of a particular territory, a larger framework is provided by the United Nations Guiding Principles on Internal Displacement (“UNGPID”). By recognizing “natural or human-made disasters” as one of the reasons forcing or obligating persons or groups of persons to leave their habitual residences within the definition of “internally displaced persons,” the UNGPID brings climate-induced migrants within its sweep. Principle 3 recognizes the nation’s responsibility and duty toward the persons internally displaced within its jurisdiction to provide them with protection and humanitarian assistance. When it comes to persons having particular attachment with and dependency on their lands, Principle 9 bestows a special obligation on the nation to protect such persons from displacement. Principle 15 clothes internally displaced persons with the right, *among other*

things, to seek refuge in a different part of the country and be protected against forceful return or resettlement at places where risk may be posed to their life, liberty, safety, and health (UNOCHA, 2001).

In the international arena, there has been felt a lack of a global framework to address the issue of climate change-induced displacement. The United Nations Framework Convention on Climate Change (UNFCCC) bears only a passing remark to displacement. The Convention Relating to the Status of Refugees 1951 has failed to aid climatic disaster-induced migrants. The most basic requirement for a person to be covered under the Refugee Convention is “fear of being persecuted” on racial, religious, or other grounds (UNRA, 1951). In the case of a climate migrant, there is no question of fear of persecution; on the contrary, it is the primal fear of loss of life and property due to causes not under anyone’s immediate control. Such migrants are traditionally not entitled to the benefits under the Refugee Convention. In 2015, the New Zealand Supreme Court, while denying refugee status to a Kiribati citizen because of non-satisfaction with the definition of “refugee” due to no “fear of being persecuted,” recognized the need for protecting persons displaced because of environmental degradation attributable to climate change or other disasters (*Ioane Teitiota*, 2015). The application made before the Human Rights Committee under the Optional Protocol to the International Covenant on Civil and Political Rights was unsuccessful. However, the HRC recognized the obligation of the states to refrain from returning a climate migrant forcibly to places where there is a clear risk to their right to life (Sinclair-Blakemore, 2020). In turn, this judgment also acts as a guideline to states to objectively consider and weigh the far-reaching effects of climate change while adjudicating the issues of the grant of asylum and the rights of refugees.

While an easy way out may seem to enlarge the definition of the term “refugees” in the Refugee Convention to include the migrant victims of climate change, there is a lurking fear that bringing such a definition would dilute and devalue the victims of persecution and overwhelm the rehabilitation mechanism already stretched to its limit. Even if such a definition is expanded, it will cover only cross-border migrants, not those internally displaced.

Lester Brown was the first to propose the term “environmental refugee” for a person displaced by environmental causes (Brown et al., 1976). The International Organization for Migration (“IOM”) has proposed a progressive and inclusive definition for environmental migrants who were described as “persons or groups of persons who, for compelling reasons of sudden or progressive changes in the environment that adversely affect their lives or living conditions, are obliged to leave their habitual homes, or choose to do so, either temporarily or permanently, and who move either within their country or abroad” (IOM, 2017).

The Institute for Economics and Peace has released a study revealing that at least 1.26 billion people would be victims of climate change displacement by 2050 (IEP, 2021). In 2018, the United Nations adopted the Global Compact for Safe, Orderly, and Regular Migration, which provides that governments should endeavor to protect climate migrants in countries of arrival by providing planned relocation and

rehabilitation and visa options if it is not possible to return such migrants to their countries where they were faced with disasters.

According to the United Nations High Commissioner for Refugees (UNHCR), each year since 2008, more than 21.5 million people had faced migration the world over because of climate change-related disasters (UNRA, 2016). The report further reminds us that it is not only the stray incidents of disasters themselves but also shortages in food and water and increased difficulties in access to natural resources that lead to such migration. Climate migrants are typically impoverished people. Migration is perhaps their very last response to adapt to the impacts of climate change, availed only by people who have permanently lost their homes, hearth, and livelihood to the far-reaching impacts of climate change. In the circumstances, climate change refugees find themselves in a precarious and unregulated position.

Sundarbans: A Unique Ecosystem

The Sundarbans (“Sundar” in Hindi language means beautiful and “Bans” mean forests) means “beautiful forests” or variably “forest of the Sundari trees or mangroves.” It is the deltaic forest region in the southern parts of West Bengal and Bangladesh formed by the deposition of silt from the mighty Hooghly, Padma, Brahmaputra, and Meghana rivers and their numerous distributaries before flowing into the Bay of Bengal. The forest is about 10,000 km², out of which about 4260 km² lies in India (Pani et al., 2012). Affected by outward current from the numerous rivers and inward current from the sea, this area has seen simultaneous land erosion on the one hand and land formation on the other for thousands of years. The rivers’ frequent watercourse changes and their numerous distributaries have also affected the newer land formation and washing away of older lands. The low-lying land in this area is thus in a state of relentless flux (Ghosh, 2017), being constantly affected by several external factors such as silt deposition, river currents, tidal currents, change of river courses, etc.

The unique ecosystem of the Sundarbans area has permitted the development of unique varieties of flora and fauna. The sweet water from the rivers and the saline tidal water from the Bay of Bengal have led to a widespread transition ecosystem of mangrove forests, locally known as “Sundari” trees, to develop. The pneumatophores or breathing roots of these trees rise upward from the anaerobic muddy soil to breathe in oxygen. The unique ecosystem created by these trees serves as the habitat for varieties of aqua flora and aqua fauna. This apart, the dense forests of the Sundarbans create a natural carbon sink and a natural cyclone barrier for the rest of West Bengal, particularly the low-lying Indo-Gangetic plains and the capital city of Kolkata (Chowdhury et al., 2021). Since time immemorial, the Sundarbans have protected West Bengal from devastating cyclones originating in the Bay of Bengal. More than 3.5 million of the populace are dependent on the Sundarbans for their livelihood (Mukul et al., 2020).

Over the years, the melting of the polar ice caps has contributed to an average global rise of sea level at about 2 mm per year. However, the heavy volume of

suspended sediment load in the Hooghly, Padma, Brahmaputra, and Meghana waters has escalated the rise of sea level in the Sundarbans region to about 3.14 mm per year (Jumde & Kumar, 2018). The elevation of the Sundarbans is between 0.9 and 2.11 m. The islands, being eco-sensitive regions, are also experiencing subsidence between 2 and 4 mm per year (Krien et al., 2019), mainly attributable to the natural compaction process because of deposits of silt brought in by the rivers.

Out of 102 islands in the Sundarbans delta region in West Bengal, about 54 are inhabited. Recurrent pre- and post-monsoon cyclones in the area have made the inhabitants of these islands vulnerable to loss of life and property. The 2007 Intergovernmental Panel on Climate Change identified climate change to be the biggest threat to the ecology of the Sundarbans, particularly to its mangrove forests (IPCC, 2007). Lohachara was the first inhabited island in the world to vanish under the rising sea level, creating the first climate refugees, whom the government moved into the largest island of Sagar. Other islands like Kabasgadi, Suparibhangha, Talpatti, and New Moore have gradually disappeared underwater (Hazra et al., 2004). The island of Ghoramara has reduced to half its size, while Mousuni island has shrunk by 20% (Danda & Mukhopadhyay, 2019). The frequent inundation of these islands and the severe land erosion in their peripheral regions have adversely affected the plant, animal, and aquatic lives therein and have negatively impacted the life, livelihood, and property of the region's inhabitants. Due to recurrent flooding, fishing, the primary source of livelihood for the area's populace, has severely suffered. The rise in sea levels has also majorly affected the fertile northern tracts of agricultural land, where standing water has been a menace resulting in the rotting of crops. The high school at Rangabelia has lost half of its playground to the rising water levels. The apocalyptic landscape left behind by Cyclone Sidr (November 2007), Cyclone Aila (May 2009), Cyclone Phailin (October 2013), Cyclone Hudhud (October 2014), Cyclone Fani (May 2019), Cyclone Bulbul (November 2019), Cyclone Amphan (May 2020), and Cyclone Yaas (May 2021) is hard to imagine. The recurrent cyclones in the Sundarbans with increased ferocity and frequency have been directly attributed to the rise in greenhouse gases resulting in further climate change. The Category 5 Cyclone Amphan, in the middle of the raging first wave of the Covid-19 pandemic, caused irreparable damage to life in the Sundarbans, inundating huts, cattle, trees, embankments, and paddy fields. About 28% of the mangrove forests were apprehended to have faced severe destruction (Sen, 2020). Inundation of fields and ponds with saline water killed fishes and left the fields unfit for agriculture for long times to come.

Due to adverse living situations, people from Sundarbans have been forced to migrate inward to higher lands. Some people have moved so temporarily, returning to their homes every time the water recedes, and they are in a position to earn some livelihood through agriculture or fishing. Some people have been forced to move permanently to larger islands like Sagar or even more inward to Kolkata and its adjacent areas, because of having lost their home and hearth to the frequent flooding in the region or the rising sea levels. However, the way of life in the bigger towns and cities and its costs have forced some of these migrants to return to ill-abled bodies bearing burdens of substantial medical expenses. While experiences with migration

have been manifold, it is primarily the elderly and the children who have stayed back in the southernmost islands. The inhabitants of the peripheral regions of these islands have to move in the pre- and post-monsoon phases every year, which contributes to the social and economic instability in their lives. Like the vulnerable ecosystem of the Sundarbans itself, its poor inhabitants also live in constant flux, their lives adversely affected by land erosion, island subsidence, rising water levels, cyclones, floods, loss of mangroves, etc.

It has somehow been the accepted notion that the only two states in India taking proactive measures to prevent floods and reduction of mortality rates resulting therefrom are Odisha and Andhra Pradesh (Jolly & Ahmad, 2019). However, by reason of the increasingly severe soil erosion in coastal regions, the outermost islands of the Sundarbans have systematically moved the residents thereof to Sagar Island, resulting in a further drain of resources and infrastructure problems for these larger islands (Samuel, 2021). Sagar Island in southwest Sundarbans stands, already reeling under the pressure of increasing population, exposed to the wrath of the Bay of Bengal (Medhi, 2021), fearing further cyclonic storms, subsidence, sea-level rise, and saltwater intrusion. In fact, since the 1990s, Sagar Island itself has been experiencing devastating effects of climate change, along with gradual incoming sea because of erosion of its peripheral areas. A 2014 strategy report by the World Bank suggests that embankments in the region are themselves a liability, providing a false sense of security to the inhabitants in the area while themselves being susceptible to erosion (World Bank, 2014). However, the devastation caused by the latest series of cyclones in the area has set the government into motion. Under the Mahatma Gandhi National Rural Employment Guarantee Act 2005, 5 crore mangrove is being planted in the Sundarbans Biosphere Reserve by adopting a community-based ecological mangrove restoration process in the area (Ahuja, 2022).

The climate change in the Sundarbans area has triggered numerous destructive effects on the land and its people. The rising sea level has led to increasing salinization of soil and water, which has further reduced the productivity of the land primarily dependent on agriculture. The soil erosion and the capsizing of embankments have led to a lack of availability of safe drinking water, decreased food security, and inadequate water, sanitation, and hygiene facilities. This has led to poor health, increased illness, and high diarrhea-related mortality, particularly among children (Sengupta, 2020). Ironically, only about 3% of the migrants from the Sundarbans attribute their displacement directly to environmental factors (Ghosh, 2018).

Kolkata: The Precariously Placed State Capital

The capital city of the state of West Bengal, Kolkata, is located along the eastern bank of the Hooghly river in the lower Ganges Delta. Reclamation of wetlands in and around Kolkata has been done gradually to accommodate the enormous population bursting at the seams (Chatterjee, 2008). Consequently, Kolkata has had to

reinvent itself and presently sits mostly on alluvial soil and within a zone considerably prone to earthquakes. According to the 2011 census, Kolkata is the seventh most populated city in India. In 2021, the Kolkata Metropolitan Area recorded more than 15 million registered voters.

It is apprehended that the sea level will rise by 1.4 meters in Kolkata by the turn of the century. As part of the low-lying Bengal basin, Kolkata lies between 1.5 to 9.0 m above sea level. Using the data from the 2021 report of the Intergovernmental Panel on Climate Change, Climate Central has created a map depicting the cities that may be underwater by 2030, and the six cities under a warning are Amsterdam (Netherlands), Basra (Iraq), New Orleans (United States), Venice (Italy), Ho Chi Minh City (Vietnam), and Kolkata (Sharma, 2021).

Such fear of inundation is real in Kolkata because of its low elevation. The increased risk of floods has been further driven by urbanization and global climate change. The urban poor in Kolkata typically resides in clustered settlements in low-elevation areas that see an increased danger of flooding (Revi, 2008). If climate change is not arrested, it is feared that more than 50% of the residents of Kolkata and its suburbs shall become victims of climate change and shall be driven out of their homes (Mukherjee, 2015).

According to a 2009 study by WWF International, Kolkata ranks third in Asia so far as climate vulnerability ranking is concerned. It is the fourth most exposed in terms of exposure to climate impacts and sensitivity of people, assets, and GDP. It has the second-lowest adaptive capacity to climate change (WWF, 2009).

Climate change affects not only the migrants but also the ecological balance of the area they are migrating to. Given the inadequacy of living opportunities to set up homes and hearths in the core areas of the destination, settlements are generally set up in peripheral areas, sometimes at the cost of massive deforestation. The living condition in such areas leaves a lot to be desired, leading the climate migrants to resort to unsustainable means to manage the natural resources in such places. Thus one instance of mass migration often leads to another vicious cycle of the beginning of climate change in the destination area. It is apprehended that Kolkata will face one of the biggest climate migration challenges as inundation in the Sundarbans area of both India, and Bangladesh will force millions to enter Kolkata in search of shelter and livelihood. The quality of life for these migrants decreases manifold. From living in areas with vast open fields, ponds, etc., they are pushed into living in cramped, dirty, and unhygienic slums in Kolkata's poor neighborhoods and its adjoining areas. This may further lead to the rapid urbanization of such adjoining regions, thereby creating challenges for local bodies to improve health, sanitation, roads, and infrastructure on a war footing, resulting in a significant ecological disturbance.

However, not much option is left to the impoverished people, who have left their original habitats because of the sinking of those islands and have further experienced the loss of life, property, and livelihood on the island of Sagar, where they had once been relocated. The last resort for them is to enter inward toward Kolkata, settle at the city's outer limits with their meager belongings, and toil hard at poorly waged, unskilled jobs to make ends meet. Mostly they build houses in violation of the municipal building rules and sometimes even in the floodplains, thereby accelerating

soil erosion, deforestation, and choking of available drainage facilities, leading to the deterioration of public health. Kolkata being located in the coastal plains, this precarious situation can further contribute to a rise in sea level.

The migration of people from Sundarbans to Kolkata has become a routine affair. According to a report by DECCMA (Deltas, Vulnerability, and Climate Change: Migration and Adaptation), about 70% of households in the Sundarbans have at least one member settled for work outside the area. Thirty percent of these migrants move outside West Bengal, and a small percentage move to the Middle East. The rest migrate closer to home to Kolkata and its adjoining areas (DECCMA, 2018). This is facilitated by the South Eastern Railways network and road network from Kolkata to the interiors of the Sundarbans and some middlemen. Many of the islanders commute daily to work in Kolkata; some stay and work in Kolkata during the weekdays and return to their villages during the weekends. Over time, some of such migrations have ended up in permanent settlements. Places like Basanti and Mollakhali in South 24 Parganas derive their names from islands in the Sundarbans, indicating the high presence and settlement of climate refugees in such areas. The DECCMA Project also reveals that around 83% of men migrate compared to 17% of women who leave the Sundarbans following their marriage (Basu, 2021). However, this trend has been changing. The number of female migrants has been increasing, particularly in the city of Kolkata and the peri-urban areas, where they are working as domestic helpers (Ghosh, 2018).

The Present Framework or Is There One?

India does not have any law addressing the issues of the climate migrants who have been forced to move internally. The National Action Plan on Climate Change 2008 focuses on broader issues like utilizing solar energy, properly managing water resources, increasing energy efficiency, developing a sustainable agricultural framework, and sustainable urban habitats as responses to the looming climate change issue (GOI, 2008). However, no policy has yet been formulated to categorically deal with the problems faced by climate migrants and provide long-term solutions. This situation is not typical to India alone. Most South Asian countries recognize displacement attributable to climate change but can undertake little to address the same in a significant, impactful manner (Kugelman, 2020). Though providing separate policies for coastal zone management, India's action plan falls woefully short when it comes to focusing on climate-induced displacements. There is no policy for strategic rehabilitation and relocation of climate refugees. Instead, the focus is on short-term measures like temporary relocation, reconstruction, etc. There is hardly any available reliable data regarding the number and situation of climate migrants. The national action plan calls for climate adaptation but fails to provide a concrete resettlement plan for victims of climate change. There has been some degree of public participation in the matter through NGOs. However, the Indian government has failed to get itself directly involved in addressing the grim issues staring at

it. Merely providing a flood warning system or a targeted public distribution system or SOPs for flood victims does not absolve the national government of its liability.

The West Bengal State Action Plan on Climate Change has also failed to provide any policy for the relocation and rehabilitation of climate migrants (GOWB, 2017). The policy does not even recognize the concept of climate migration or climate refugees. None of the adaptation strategies prescribed by the action plan cater to the needs of climate refugees.

The Glasgow Conference 2021 (COP-26) and Its Takeaways

The 26th United Nations Climate Change Conference was held between October 31, 2021, and November 12, 2021, in Glasgow, Scotland. The Glasgow Climate Pact recognizes the problems of climate-related migration and displacement (GCP, 2021). An important takeaway from the conference is that rich countries have collectively pledged to double the funding for climate adaptation projects by 2025. Once realized and appropriately channelized, this will enlarge the window to adapt to climate change, further pushing back and preventing the need to opt for migration as a last resort. The Adaptation Fund has raised more than triple the budget for the previous year, with the United States pledging to the fund for the first time. Better funding would enable the local adaptation efforts to reach fruitful results and prevent the occurrence of migration.

While the Glasgow Climate Pact reaffirmed the desire of all participating countries to arrest global warming to 1.5 °C, the pledges undertaken, however, set the goal at 1.8 °C. Previous experience shows that commitments mean little so far as these negotiations are concerned. If the current situation is allowed to remain, global warming will be on course to reach 2.7 °C. The difference of 1.2 °C would translate into hundreds and thousands of further displacements.

Rich countries have failed to honor their pledges of 100 billion USD per year to help devise a mechanism for poorer countries to mitigate the damages resulting from climate change, suitably adapt to it, and push further migration requirements. As far as the issue of loss and damages due to climate change is concerned, COP26 realizes that adaptation can be stretched only to a limit, and when it comes to permanent and irreversible losses, such as displacement, the countries that have historically contributed more to greenhouse emissions have a responsibility to provide funds to other countries to address the harmful effects of their mistakes. Poorer countries are rooted in establishing Glasgow Loss and Damage Finance Facility to mobilize money specific for redressal of loss and damages. Though Scotland and a group of philanthropic organizations agreed to lead the way by pledging grants, the same did not materialize. Instead, a less ambitious Glasgow Dialogue was adopted to convene between 2022 and 2024. Countries also agreed to commit to Santiago Network, a body aimed at building technical expertise in dealing with loss and damage, including migration and displacements relating to climate change.

Harnessing the Indian Legal Framework

The Constitution of India is not static but a living and organic document that evolves with the changing times and the populace's needs. Article 21 of the Constitution of India applies to both citizens and noncitizens alike. It guarantees the right to life and personal liberty to every individual. The right to live in a healthy and pollution-free environment has been recognized as an essential limb of the fundamental right to life (M. C. Mehta, 1987). The apex court has further construed "environment" to be of broad spectrum and to contain within its ambit "hygienic atmosphere and ecological balance" (Virender Gaur, 1995). Article 48A imposes a duty on the state to protect and improve the environment. Article 51A(g) imposes a similar duty on the citizens of India as well. Also, the Indian jurisprudence on the environment has recognized the environmental rule of law as a facet of the concept of the rule of law. In enumerating the role of all stakeholders in formulating strategies to deal with the challenges posed in implementing the environmental rule of law, the Supreme Court of India has recently recognized the destruction of habitats caused by environmental degradation and climate change (Himachal Pradesh Bus-stand Management and Development Authority, 2021).

However, mere recognition is not enough. It is high time that the preservation and protection of Article 21 rights of the victims of climate change be taken up in right earnest. The hapless homeless victims of climate change cannot be expected to approach the constitutional courts in a bid to enforce their rights by seeking appropriate writs. The gravity of the situation is enough to demand *suo moto* action from the courts. The central and state governments ought to be directed to frame policies under the national and state action plans, respectively, for relocation and rehabilitation of the climate migrants and their synthesis into the mainstream society at the place of migration. Infrastructure and capacity building in Kolkata and its suburban areas need immediate attention. For this purpose, the National Disaster Management Act 2005 may be invoked not only at the site of climate change but also at the site of migration. The minimum standards of relief as contemplated under the act should be made available to climate migrants. Under Section 2(d) of the 2005 Act, the definition of "disaster" is wide enough to cover the migrants affected by climate change-related disasters. Accordingly, the authorities established under the act at the national, state, and district levels may be called upon to address the woes of climate migrants on an urgent basis. The central and the state governments may further be called upon to allocate funds for the purpose and to take further mitigating steps to make the migration, rehabilitation, and resettlement process smoother for the climate refugees after speedy and adequate capacity building at the place of relocation.

The National Institute of Disaster Management and the National Disaster Response Force established under the 2005 Act ought to be sensitized to the uniqueness and special needs of climate migrants, and they ought to be dealt with empathy. The National Policy on Disaster Management fosters a strategy of prevention, mitigation, preparedness, and response. However, the continuing nature of climate change disasters would require a collaborative and symbiotic harnessing of

pre-disaster prevention, mitigation, and preparedness in sites brutally affected by climate change and simultaneous post-disaster response, rehabilitation, reconstruction, and recovery in sites of consequent migration.

Conclusion: Management and Mitigation

The scathing effects of climate change on the Sundarbans are real and visible. The apocalyptic landscape is presented by acres after acres of inundated land with washed away huts, properties, as well as the future of the inhabitants of the Sundarbans after each extreme weather condition triggered by cyclones and erosion, and subsidence is for all to see. While migration to Kolkata and its adjoining areas may provide some short-term relief to some of such unfortunate people, not everyone has the wherewithal or the desire to leave their home and hearth and settle in a foreign land. In these circumstances, it is crucial to devise a mechanism for proper management of such migration and adaptation-focused mitigation of climate change factors so that the phenomenon of migration can be slowly put an end to.

The first step in such mitigation is to realize and recognize that the regions that contribute the least to global climate change are the ones most severely affected by it. The unique ecosystem of the Sundarbans has become an unwitting victim to the rampant exploitation of world resources by developed and developing countries the world over. Accordingly, the primary focus should be on reducing carbon emissions to limit global warming to between 1 to 1.5 °C in keeping with the Glasgow Climate Pact.

The importance of the Sundarbans as a cyclone shield for Kolkata cannot be overemphasized. The depletion of mangrove forests in the Sundarbans had already left its mark during the frequent cyclones in southern Bengal when Kolkata was devastated by the accompanying storms. In recent years, both the frequency and intensity of tropical storms have increased manifold. As such, restoration of mangrove forests is a viable low-cost-high-benefit action that can be implemented to meaningfully protect the coastal areas of West Bengal, which would, in turn, protect Kolkata from direct fallouts of further instances of cyclones.

There is further a need to effectively implement various social schemes like the Kendriya Awas Yojana, Geetanjali, Kanyashree, Rupashree, MNREGA, etc., in the Sundarbans. However, the extent and benefits of the schemes should be amplified to provide not enough for just mere sustenance but for the development of the vulnerable people of the area. The development of medium and small industries in areas of relocation can also help in providing better adaptability and mitigation options to the displaced population. Crop insurance can also be critical in empowering small farmers of the area. There is a requirement for the intervention of the government by assisting local people of the Sundarbans in building cyclone-resistant houses and cultivating saline-tolerant variants of paddy instead of the high-yield varieties that cannot survive saline waters at all. There is a further need to provide access to the Sundarbans' people to fresh water by implementing processes for rainwater harvesting and watershed management (Basu, 2021).

Migration from the Sundarbans can be avoided in the long run only if people manage to live and flourish in smaller tracts of land. A shift to high-value sustainable agricultural practice, improved pisciculture, and a dedicated focus on the development of tourism with emphasis on the typical and unique ecology of the area can address the economic crisis of the inhabitants of the Sundarbans to a great extent. The state and the central governments should collaborate in developing an action plan to provide for the same and assist the people in building cyclone-resistant houses on raised land. For the people who have migrated or are desirous of doing so, the government should take steps to maintain proper records of such inhabitants, along with their skill sets, and take steps to ensure their livelihood and security in the areas they move to.

Australia, Alaska, and other countries have made planned mass migration successful ventures through effective governmental intervention and investment. If seen as an adaptation mechanism and not merely as a helpless last resort, migration of skill sets can take advantage of opportunities in other places. Presently, the migration from Sundarbans is one of negative connotation and primarily of human labor. If the inhabitants in the area can be sufficiently trained in particular skill sets, their migration will be more of an asset than a liability and can be looked at as a livelihood option.

The role of the media in addressing issues of this magnitude cannot be over-emphasized. Presently, the Indian media provides very little coverage of the issue of climate change. If at all, such coverage is restricted to environmental issues like air pollution, noise pollution, etc. There is very little coverage on localized matters typical to Kolkata, like the sea-level rise or the plight of the climate migrants. The media needs to assume a manifold proactive role, preferably with the use of vernacular language, to convey to the general public the clear and present dangers manifested by climate change and the plight of the climate migrants. While presently intermittently covering the issue of migration from the Sundarbans to Kolkata, the media is doing so in the socioeconomic context, while ignoring the climate-related displacement aspect of it altogether. Considering the tremendous impact of climate change and climate change migration, the media must play an agenda-setting role, thereby influencing the discourse and deliberation toward climate change, building public opinion on the issue, and driving every single person to realize and recognize the threats relating to climate change and take proactive steps at an individual level to address the issue. Instead of treating them as isolated events, the media should clearly link major and extreme weather events to climate change.

Only coordinated and collaborative efforts at channelizing all of the above-suggested measures and implementing the same at war footing can deliver a long-term sustainable solution to the dangers the Sundarbans and Kolkata are facing shortly. The central and state governments, along with active and informed public participation, can emerge as the major players in this race, while effectively roping in the private sector in infrastructure and capacity-building programs. With these suggested measures being implemented and firmly put in place, along with the world sincerely attempting to tackle climate change, one can hope for better days to dawn on the Sundarbans and Kolkata.

Abstract

The present paper aims at expounding the role and importance of animals in the forecast of natural disasters.

Undoubtedly, animals are not just friendly to human beings, but indeed human life is inevitably indebted to animals in many ways. In fact, animals are those speechless creatures, who cannot express themselves through words yet their anxieties, behavioral changes, and responses suggest strong and accurate instinct to identify coming of a disaster.

This chapter will be an attempt to highlight the importance of animals in natural disasters.

Keywords

Calamity (*āpadā*) · Animal (*paśu*) · Village (*grāmya*) · Forest (*āranya*) · Air (*vāyavya*)

Background

Human, animals, and trees are considered animate creatures. All these are interlinked with each other in many ways for their existence. The importance and position of animals are rooted in the fact that human life is indebted to animals in many ways. Like human beings, animals also react toward situations both adverse and favorable ones.

Since ancient period human life is continuously adapting and protecting oneself from natural disasters. In contemporary times, forecast of natural disasters can be made with the help of scientific devices, use of artificial intelligence, and a variety of sophisticated early warning systems, yet most reports have suggested their failures when disasters actually struck any region. In Kedarnath disaster of 2013 in which 4000 people died or again in the Rishi Ganga glacier burst of 2021 (Bhatnagar, 2021) as well as in the massive 2018 floods (Singh et al. 2018) in the country's most developed and educated state, Kerala, these human machines failed repeatedly. In ancient Indian literature, animal behavior plays an important role in the forecast of natural disasters.

Introduction

On the basis of ancient Indian literature, we may say that animals are full of intellect; they are used as symbols to certain noble acts as well as reflection of human behavior where the narratives on animals are extraordinary. Indian treasure tales in Sanskrit texts propound the importance of animals which will be clear from the following pages and also the references wherever relevant.

Definition of Animal (*paśu*)

It is amazing that ancient Indian texts which weaved morality, ethics, and spirituality laws for human beings have written extensively on animals and the virtues which they exhibit for human learning. Basically, the word *paśu* means all the beings who could see with their eyes. Yāska in *Nirukta*¹ states that all the creatures using their eyes to see the world are known as *paśu*. *Śatapatha Brāhmaṇa*² of Śukla Yajurveda mentions that all the animals are the subjects of the deities.

¹ *Paśuh paśyateh. -Nighaṇṭu and The Nirukta.* Lakshman Sarup. 2002, Reprint, Delhi: Motilal Banarsiidas Publishers, 3.16

² *Daivyo viśo yatpaśavah. - Śatapatha Brāhmaṇa,* 1.8.1.36

- *Aviśeṣeṇa sarvam pasyatītī.*³
- Any animal or brute or beast (also applied contemptuously to a man).⁴

Types of Animals

Animals are considered as valuable treasure in ancient Sanskrit literature. *Śatapatha Brāhmaṇa* propounds that animals are wealth.⁵ Animals are worshipped as divine powers and have inevitable place in human life, so they are called *mahī*⁶ (powerful).

Since Vedic period animals are worshipped and adored. *Rigveda*⁷ mentions three categories of animals:

- Reside in village (*grāmya*)
- Live in forest (*āranya*)
- Fly in the air (*vāyavya*)

God created animals like birds, goats, sheep, cows, horses, donkeys, beasts, camels, etc.⁸

Atharvaveda states that wild animals like tiger, etc. dwell in the forest and they are called wild animals⁹ and also rural animals stay far from forest animals.¹⁰ Rudra has categorized animals in five species, viz., cows, horses, men, sheep, and goats.¹¹

Caraka¹² explains eight types of animals:

(a) *Prasaha*

Suddenness and force with which they seize their food and eat

³ *Uṇādi-Koṣa*, 1.28

⁴ *Paśu, A Sanskrit-English Dictionary*, Monier Williams. 1986, Reprint, Delhi: Motilal Banarsi Dass Publishers, p.611

⁵ (i) *Śrīhi paśavah.- Śatapatha Brāhmaṇa*, 1.8.1.36

(ii) *Paśavo vasuh. - Śatapatha Brāhmaṇa*, 1.8.1.36

⁶ *Paśavo vai mah.- Śatapatha Brāhmaṇa*, 11.8.1.3

⁷ *Paśūn tāniś cakre vāyavyān āranyān grāmyāś ca ye. - Rgveda*, 10.90.8

⁸ *Tasmād aśvā ajāyanta ye ke cobhayādataḥ.*

gāvō ha jājñire tasmāt tasmāj jātā ajāvayāh.- Rgveda, 10. 90.10

⁹ *Ye ta āranyāḥ paśavo mrgā vāne hitāḥ. -Atharvaveda*, 12.1.49

¹⁰ *Vi grāmyāḥ paśava āranyairvi. - Atharvaveda*, 3.31.3

¹¹ *Tatharvavedaeme pañca paśatharvavedao vibhaktā gāvō aśvāḥ pūruṣā ajāvayah.*
- *Atharvaveda*, 11.2.9

¹² *Prasahya bhakṣayantītī prasahāstena samjñitāḥ.*

Bhūśayā bilavāsityād ānūpānūpasamīśrayāt.

Jale nivāsājjalajā jalecaryāj jalecarāḥ.

Sthalajā jāngalāḥ proktā mrgā jāngalacāriṇāḥ.

Vikīrya viśkirāśceti pratudya pratudāḥ smṛtāḥ. -Caraka Saṁhitā, Sūtra-sthāna, 27.52–54

- (b) *Bhūśaya*
Living in holes
- (c) *Ānūpa*
Living in marshy tracts
- (d) *Jalaja*
Living in water
- (e) *Jalecara*
Living on the surface of water
- (f) *Jaṅgāla*
Living and moving on the land
- (g) *Viskira*
Scatter on earth and hills, etc. and use their claws or hoofs or mouth to find their food
- (h) *Pratuda*
Peck at their food

Another classification of animals is available in *Suśruta Saṃhitā*, which is as follows: firstly, there are six types of animals and later they are divided in to two major categories.¹³

Forecast of Natural Disasters by Animals

Ancient Sanskrit literature illustrates that ants, elephants, horses, and other animals warn about the forthcoming of natural disasters. Accordingly, sudden changes in the behavior of animals can be a signal of natural calamities. So, the main focus of the chapter will be the study of behavioral changes of animals as an alarm for natural disasters. References from ancient literature are as follows:

- If a horse while eating dry grass or wood starts making sounds, it means a natural disaster associated with fire may occur shortly.¹⁴
- If a horse makes sound putting his mouth down in a pond, etc. where water is full of moss, this situation creates the fear of fire disaster.¹⁵

¹³ *Jaleśaya ānūpāḥ grāmyāḥ kravyabhujaḥ ekasaphāḥ jāṅgalāśceti ṣaṇmāṇsavargābhavanti. . . . te Punarvidhā jāṅgalā ānūāśceti.* -*Suśruta Saṃhitā*, Sūtra-sthāna, 46.1

¹⁴ *Śuṣkam kāṣṭham tṛṇam vā'pi yadā saindanīśate hyāḥ.*

Heṣante sūryamudvīksya tadā'gnibhayamādiśet. -*Bhadrabāhu Saṃhitā*, 14.167

¹⁵ *Yada śaivālajale vā'pi magnam krutvā mukham hyāḥ.*

Heṣante vikṛtā yatra tadāpyagnibhayam bhavet. -*Bhadrabāhu Saṃhitā*, 14.168

- If ants make their holes nearby human habitat and also move toward forests from town, it is an alarm of major disaster for a nation.¹⁶
- Where ants move fast in their groups, this situation should be understood as demolition of a nation.¹⁷
- When groups of ant tremble and die on their own, a calamity may be expected.¹⁸
- When ants go upward with feathers, this condition brings a lot of rain.¹⁹
- When bull sounds loudly and activates its hump, it causes hazards.²⁰
- While riding an elephant, if its ivory breaks out, it causes the death of the king.²¹
- Breaking of teeth of cat, mongoose, owl, crow, and herons causes hazards.²²
- When horses make loud sounds and look at one another, it will create a harmful situation for the people of the country.²³
- Sudden hairfall of horses indicates upcoming calamities.²⁴
- Loud and awful sound of a deer warns about the destruction of a village, and also if it makes sound facing the sun, it is harmful for the military of a country.²⁵

For Services They Rendered Inadvertently, Animals Were Protected

The role and importance of animals are unavoidably accepted in the literature. Each animal has its own significant position. It should be an important duty of human beings to protect, save, and care for animals as that is where the welfare of entire world is indicated. In Vedic literature a number of prayers for protection of animals are found, which proves that the life of animals is as important as any other living being. A list of few instances is as follows:

¹⁶ *Valamīkasyāśu janane manujasya niveśane.*

Araṇyam viṣataścaiva tatra vindyānmahadbhayam.- Bhadrabāhu Saṁhitā, 14.51

¹⁷ *Mahāpipīlikāvrundam sandrakāviluptam.*

Tatra tatra ca sarvam tadrāṣṭrabhaṅgasya cādiśet.- Bhadrabāhu Saṁhitā, 14.52

¹⁸ *Mahāpipīlikārāśirvisphurantī vipadyate.*

Uhyānuttishate yatra yatra vindyānmahadbhayam -Bhadrabāhu Saṁhitā, 14.53

¹⁹ *Śvaśvapipīlikāvrundam nimnamūrdhvam visarpati.*

Varṣam tatra vijāṇyādbhadrabāhuvaco yathā.- Bhadrabāhu Saṁhitā, 14.54

²⁰ *Urdhvam vruṣo yadā nardet tadā syācca bhayankarah.*

Kakudam calate vāpi tadā'pi sa bhayankarah.- Bhadrabāhu Saṁhitā, 14.139

²¹ *Kṣīyate vā mriyate vā pañcamāsāt param nrupāḥ.*

Gajasyārohaṇe yasya yadā dantah prabhidyate.- Bhadrabāhu Saṁhitā, 14.147

²² *Vidāla-nakuloulūka-kāka-kaṁsamaprabhaḥ.- Bhadrabāhu Saṁhitā*, 14.149

²³ *Pārśve tadā bhayam brūyāt prajānāṁśubhīkaram.*

Anyonyam samudīkṣante heṣyasthānagatā hayāḥ.- Bhadrabāhu Saṁhitā, 14.152

²⁴ *Yadā bālā prakṣarāt vindyānmahadbhayam.- Bhadrabāhu Saṁhitā*, 14.165

²⁵ *Bṛhatsaṁhitā*, Varāmihira with English Translation, Subrahmanya Sastri, 1946, Bangalore: V.B. Soobbiah & Sons, 30.1

- A prayer to God *Pūṣan* is: May the God *Pūṣan* follow our cows, may he keep our horses safe and sound, let none of the cattle be lost, none injured, none sink in a pit and break a limb, may the God return our cattle safely.²⁶
- O Lord *Agni*! by moving everywhere protect the animals.²⁷
- A verse in third book of Yajurveda states: may praiseworthy *Agni*! protect my cattle.²⁸
- Wild animals are protected by God Rudra.²⁹

Killing or hunting of animals for food and entertainment is completely prohibited. Any living being should not be harmed for any purpose:

- Animal killing, liquor, and meat should be avoided.³⁰
- Feeding oneself with animal flesh is considered as the greatest sin.³¹
- *Manusmṛti* mentions seven types of animal killers such as the proposer, cutter, seller, buyer, cook, distributor, and eater.³²
- A person who kills animals for entertainment never gets happiness in his life, and he suffers even after death.³³
- Non-killing of animals leads to joy.³⁴
- A person who never kills and troubles the animals gets greatest happiness in his life.³⁵
- Killing of animals does not lead toward heavenly pleasure.³⁶

A lot of references regarding care of animals state that animals should be treated specially like other animate creatures:

²⁶ *Pūṣā gā̄ anv etu nah pūṣā rakṣatvarvataḥ.*

Pūṣā vājāṁ sanotu nah. - *Rgveda*, 6.54.5

Mākir neśān mākīn riśān mākīn śāmī sāri kevaṭe.

Athāriṣṭābhīr ā gahi. - *Rgveda*, 6.54.7

²⁷ *Bhuwanā vy akhyāḥ paśūn na gopā̄ iryāḥ parijmā.* - *Rgveda*, 7.13.3

²⁸ *Śāṁsyā paśūn me pāhi.* - *Yajurveda*, 3.37

²⁹ *Tubhyamāranyāḥ paśavo mrugā vane hitāḥ.* - *Atharvaveda*, 11.2.24

³⁰ *Varjayen madhu māīnsaiṁ prāṇināṁ caiva hiṁsanam.*

- *Manusmṛti* or *Manatharvavedadharmaśāstra*. Pandit Girija Prasad Dwivedi.1917. Lucknow: Naval Kishore Vidyalaya., 2.177

³¹ *Svamāīnsai paramāīnsena yo vardhayitum icchati.*

..... tato 'nyo nāsty apunyakṛt. - *Manusmṛti*, 5.52

³² *Anumantā viśasitā nihantā krayavikrayī.*

Sainskartā copahartā ca khādakaś ceti ghātakāḥ. - *Manusmṛti*, 5.51

³³ *Yo 'himśakāni bhūtāni hinasty ātmasukhecchayā.*

Sa jīvāṁś ca mrtas caiva na kva cit sukham edhate. - *Manusmṛti*, 5.45

³⁴ *Ahiṁsayaiva bhūtānām kāryam śreyo 'nuśāsanam.* - *Manusmṛti*, 2.177

³⁵ *Yo bandhanavadhakleśān prāṇīnaṁ na cikīrṣati*

Sa sarvasya hitaprepsuḥ sukhām atyantam aśnute. - *Manusmṛti*, 5.46

³⁶ *Na ca prāṇivadhaḥ svargyastasmān māīnsaiṁ vivarjayet.* - *Manusmṛti*, 5.48

- Animals should be protected from cowherd thieves, wild beasts and foes, etc.; also animals should be taken to the forest for grazing according to the season.³⁷
- Animals should be given clean and dirt- and fungus-free water to drink.³⁸
- Same color animals should be kept in a group of tens to protect them.³⁹
- Animals should be served with sufficient grass and water.⁴⁰
- To frighten snakes and other beasts, etc., a bell should be tied in the neck of animals.⁴¹
- One sixth part of living birds and animals should be freed to live in protected safe forests known as *abhyāranya*.⁴²

Also a prayer for the well-being of animals proves that animals were protected and worshipped with prayers, “Kindly keep my cattle content.”⁴³ *Atharvaveda* mentions that one should serve the cows as they will take everyone toward heaven after death.⁴⁴

Animals and Birds Found in Ancient Literature

Vedic literature presents a long list of all kinds of animals and also elaborates their inevitable place in the life of human beings. Role and importance of select animals are as follows:

(a) Cow (*Gau/Dhenu*)

Cow is the most revered animal in Vedic literature. *Yajurveda* states that cow cannot be compared with any object.⁴⁵ *Atharvaveda* mentions that cow is the source of all kinds of prosperity.⁴⁶ Cow brings fortune to mankind:

³⁷ *Lubdhaka śvaganibhir apāstas tena'vyāla.parābādha.bhayam rtu.vibhaktam aranyam cārayeyuh.*

-The Kauṭilya Arthaśāstra, R.P. Kangle, 1969, Bombay: University of Bombay, 2.29.21

³⁸ *Sama vyūdha.īrtham akardama grāham udakam avatārayeyuh pālayeyuś ca.*

-The Kauṭilya Arthaśāstra, 2.29.23

³⁹ *Varṇāvarodhena daśatīrakṣā.* - The Kauṭilya Arthaśāstra, 2.29.39

⁴⁰ *Sarveśām tṛṇodakaprākāmyam.* - The Kauṭilya Arthaśāstra, 2.29.46

⁴¹ *Sarpa-vyāla-trāsana-arthaīn gocara anupāta jñānārthaīn ca trasnūnām ghanṭā. Tūryām ca badhnīyuḥ.* - The Kauṭilya Arthaśāstra, 2.29.22

⁴² *Pakṣimrgānām jīvataśdbhāgamabhayavaneṣu pramuñcet.*

- The Kauṭilya Arthaśāstra, 2.26.4

⁴³ *Pasiūn me tarapayata.*-Yajurveda, 6.31

⁴⁴ *Ayam te mopatistvam juṣatharvavedaa svargam lokamadhirohyainam.*-Atharvaveda, 18.3.4

⁴⁵ *Gostu mātrā na vidyate.*-Yajurveda, 23.48

⁴⁶ *Gávo bhago gáva indro ma ichād gáva somasya prathamásya bhaksah.*

Imā yā gāvah sā janāsa indra ichāmi hydā manasā cid indram.- Atharvaveda, 4.21.5

May cows come and bring us good fortune; let them stay in our cowsheds and enjoy in our company. May many coloured cows bring here prolific milk for offerings to the resplendent Lord at many dawns.⁴⁷

Vedic seer asserts that a cow should not be killed:

Let not the cows fall a victim to the arrogant, dust spurning, war - horse. Let them not fall in the hands of a butcher or his shop. Let the cattle of the man, the householder, move about free and graze out of fear.⁴⁸

Cow is compared with ultimate divinity, and desire for her blessing can be seen:

May the cows be our affluence; may the resplendent Lord grant us cattle; may the cows yield food (milk and butter) of the first libation. These cows, O men, are sacred as the Lord resplendent

Himself, -the Lord whose blessings we crave for, with head and heart.⁴⁹

A cow fulfills all the desires of human beings.⁵⁰ In fact cow is great in all aspects.⁵¹

(b) Horse (*Aśva*)

Undoubtedly, in Vedic literature, horse is a foremost animal. In first maṇḍala of *Rgveda*, Vedic seer has cited many verses regarding care and food of a royal horse:

- Care:

Due care is taken of this royal horse, who should be cleaned and decorated with rich trappings, and whilst it fights bravely against the enemies, it gets laudations and favours from the king and commanders.⁵²

A charming novice horse, representing the commander, moves in the frontline, and it is followed by the royal horse. The novice horse is put under the care of a skilled trainer, and provided with all facilities for receiving honours and glory in future.⁵³

⁴⁷ Ā gāvo agmann̄ uta bhadram akran sīdantu goṣṭhe ranayantvasme.

Prajāvatīḥ pururūpā iha syur īndrāya pūrvīr uṣaso duhānāḥ. - *Rgveda*, 6,28.1

⁴⁸ Na tā arvā reṇukakātō aśnute na saṁskrtatram upa yanti tā abhi.

Urugāyam abhayam tasya tā anu gāvo martasya vi caranti yajvanāḥ. - *Rgveda*, 6,28.4

⁴⁹ Gāvo bhago gāva indro me acchān gāvah somasya prathamasya bhaksah.

Imā yā gāvah sa janāsa indra icchāmīd dhṛdā manasā cid indram. - *Rgveda*, 6,28.5

⁵⁰ Dhenurdakṣinā dhenuriva vā iyam manuṣyebhyah sarvākāmāndhuhe mātādhenurmātēva vā iyam manuṣyānbibharti tasmāddhenurdakṣinā. - *Śatapatha Brāhmaṇa*, 5.3.1.4

⁵¹ Mahāinstveva gormahim. - *Śatapatha Brāhmaṇa*, 3.3.3.1

⁵² Yannirñijā rekñasā prāvṛtasya rātiṁ grbhītām mukhato nayanti.

Suprāñajo memyadviśvarūpa īndrāpūṣṇoh priyam apyeti pāthah. - *Rgveda*, 1.162.2

⁵³ Eṣa cchāgah puro aśvena vājinā pūṣṇo bhāgo nīyate viśvadevyah.

Abhipriyāṁ yat purolāśam arvatā tvaṣṭed enāṁ sauśravasāya jīnvati. *Rgveda*, 1.162.3

- Food:

The horse is fed with a well - cooked meal of cereals of several kinds giving out such odours, so fragrant, that even the passers - by are tempted to say, “It is fragrant, therefore give us some.”⁵⁴

Horse is one of the most powerful among all the animals.⁵⁵ It is considered as the best animal.⁵⁶

(c) Sheep (*Avi*)

Sheep is referred as an important animal. *Rgveda* compared the creator, who “weaves the cloth of creation like the raiment of the sheep”:⁵⁷

He is the Lord of the self-sustained effulgent Mother Nature, as well as of the effulgent soul. He weaves the cloth of creation like the raiment of the sheep and cleanses the vestment.

Śatapatha Brāhmaṇa referred *avi* as earth, who protects everyone.⁵⁸ Here symbolic use of animal *avi* presents its vital place in the literature.

Apart from above mentioned animals, a long list of animals is available in the literature, which proves the unconditional worth of animals: *vyāghra*⁵⁹ (lion) is considered as the king of wild animals,⁶⁰ *śaśa* (rabbit),⁶¹ *mayūra* (peacock),⁶² *ahi* (snake),⁶³

⁵⁴ Ye vājinam paripaśyanti pakvam ya īm āhuḥ surabhīr nir haretī.

Ye cārvato māṁsabhiṣṭām upāsata uto teṣām abhigūrtir na invatu.-*Rgveda*, 1.162.12

⁵⁵ • Aśvaḥ paśūnām vīryavattamaḥ.-*Śatapatha Brāhmaṇa*, 13.1.2.5

VS, 2.4.31, SB, 1.6.3.9

ākhu (mouse),⁶⁴ *rksa* (bear),⁶⁵ *kapi* (monkey),⁶⁶ *vṛka* (wolf),⁶⁷ *varāha* (boar),⁶⁸ *mahiṣa* (buffalo),⁶⁹ *matsya* (fish),⁷⁰ *nakula* (mongoose),⁷¹ *maṇḍuka* (frog),⁷² *Kūrma* (tortoise),⁷³ *gardabha* (donkey),⁷⁴ etc.

Name of Animals as an Epithet to Deities

Not convinced that the greed and conceit of humans can spare these animals, scriptures gave animal names to the gods themselves. This is explained below:

(i) Boar (*Varāha*)

The term *varāha* is denoted as synonym of *megha* in *Nighantu*,⁷⁵ the Vedic lexicon. God *Maruts* has been referred to as bearer of *varāha*.⁷⁶

Śatapatha Brāhmaṇa states *Prajapati* as *varāha*, who was raised in the form of a bear.⁷⁷

(ii) Bull (*Vṛṣabha*)

In Vedic literature, the term *vṛṣabha* is commonly used for deities such as *Indra*, *Agni*, *Rudra*, *Parjanya*, *Soma*, etc. The term signifies to pour.⁷⁸ It is used many times for *Indra*:

⁶⁴ *ākhu* (mouse) *Atharvaveda*, 4.50.1; *Taittirīya Saṁhitā*, 5.5.14.1; *Maitrāyaṇī Saṁhitā*, 3.14.7; *Śatapatha Brāhmaṇa*, 2.6.2.10

⁶⁵ *rksa* (bear) *Rgveda*, 8.68.15, *Śatapatha Brāhmaṇa*, 2.1.2.4

⁶⁶ *kapi* (monkey) *Rgveda*, 10.68.15, The synonym of word monkey is *markaṭa* is also found. - *Taittirīya Saṁhitā*, 5.5.11.1; *Maitrāyaṇī Saṁhitā*, 3.14.11

⁶⁷ *vṛka* (wolf) - *Rgveda*, 1.116.14; *Atharvaveda*, 12.1.49; *Maitrāyaṇī Saṁhitā*, 3.11.2; *Taittirīya Brāhmaṇa*, 2.6.1.5

⁶⁸ *varāha* (boar) - *Rgveda*, 10.28.4; *Atharvaveda*, 8.7.23; *Maitrāyaṇī Saṁhitā*, 3.8.3

⁶⁹ *mahiṣa* (buffalo) - *Rgveda*, 5.29.7, 10.87.7; *Maitrāyaṇī Saṁhitā*, 2.1.9; *Śatapatha Brāhmaṇa*, 7.3.1.23

⁷⁰ *matsya* (fish) - *Rgveda*, 10.68.8; *Maitrāyaṇī Saṁhitā*, 3.14.2.15

⁷¹ *nakula* (mongoose) - *Atharvaveda*, 8.7.23; *Maitrāyaṇī Saṁhitā*, 3.14.7.13

⁷² *maṇḍuka* (frog) - *Rgveda*, 7.103; *Atharvaveda*, 4.15.12

⁷³ *kūrma* (tortoise) - *Atharvaveda*, 9.4.16; TS, 2.6.3.3; *Maitrāyaṇī Saṁhitā*, 3.14.15, 3.15.3; *Śatapatha Brāhmaṇa*, 1.6.2.3

⁷⁴ *gardabha* (donkey) - *Rgveda*, 3.53.23; *Atharvaveda*, 5.31.3; *Taittirīya Saṁhitā*, 5.1.2.1, 5.1.5.7; *Śatapatha Brāhmaṇa*, 4.5.1.9

⁷⁵ *Nighantu*, I.10

⁷⁶ *Etat tyan na yojanam aceti sasvar ha yan maruto gotamo vah.*

Paśyan hiranyakārān ayodamṣṭrān vidhāvato varāhūn. -*Rgveda*, 1.88.5

⁷⁷ *Varāha ujjaghāna so'syāḥ patiḥ*

Prajāpatistenaivainametanmithunena priyeṇa dhāmnā samardhayati.

- *Śatapatha Brāhmaṇa*, 14.1.2.11

⁷⁸ *Vṛṣasecane*, *vṛṣa* + *rṣivṛṣibhyām kit.* - *Uṇādi-Koṣa*, 3.123

- Shower of bounties is your adamantine weapon and shower of blessings is your chariot; and so are your horses and armoury. You are the Lord of the spiritual happiness. May you enjoy to your satisfaction your own benign bliss.⁷⁹
- May the effective eulogium melt you, O showerer of blessings. Your radiance is borne by actinic rays. So, O showerer of blessings, splendid in form, wielder of the punitive justice, with mighty chariot, may you defend us in struggles.⁸⁰
- O resplendent Lord, you are the showerer of bliss, the bedewer of earth, the feeder of the rivers, the supplier of the aggregated waters. O fulfiller of all aspirations, you are the most excellent shedder of rain, the sweet elixir, verily, our loving devotion, as if honey-flavoured juice is offered for your acceptance.⁸¹

This epithet is also found for *Parjanya* or the god of clouds:

- I address the mighty cloud, with these invocations; I praise him with adoration. I worship him with reverence, who is the thunderer, the showerer, the bountiful, and who lays, in the plants, the seed for germination.⁸²

(iii) Cow (*Gau*)

The term *gau* represents not only a cow but the earth, the sun, and also the rays of the sun. Vedic lexicon *Nighantu*⁸³ states the synonym of word *gau* – *prthivī, aditi, vāk*, etc. The word *gau* in its plural form is used for the rays of the sun.⁸⁴ While explaining the importance of a cow and prohibiting to kill her, Vedic seer has presented her as a divine power and associated with gods:

- She is like the mother of the cosmic forces, the daughter of the cosmic matter, the sister of cosmic energy, the centre of the ambrosia- I address to men of wisdom-kill not her, the sinless inviolate cow.⁸⁵

The goddesses *Aditi*, *Idā*, and *Sarasvatī* are referred as cows in *Śatapatha Brāhmaṇa*.⁸⁶

⁷⁹ *Vṛṣā te vajra uta te vṛṣā ratho vṛṣaṇā harī vṛṣabhānyāyudhā.*

vṛṣṇo madasya vṛṣabha tvam iśiṣa indra somasya vṛṣabhasya trpnuhi. - *Rgveda*, 2.16.6

⁸⁰ *Vṛṣā tvā vṛṣaṇām vardhatu dyaur vṛṣā vṛṣabhyām vahase haribhyām.*

Sa no vṛṣā vṛṣarathah suśipra vṛṣakrato vṛṣā vajrin bhare dhāh. - *Rgveda*, 5.36.5

⁸¹ *Vṛṣāsi divo vṛṣabhad prthivyā vṛṣā sindhūnām vṛṣabhad stiyānām.*

Vṛṣne ta indur vṛṣabha pīpāya svādū raso madhupeyo varāya. - *Rgveda*, 6.44.21

⁸² *Acchā vada tavasām gīrbhir ābhīh stuhi parjanyām namasā vivāsa.*

Kanikradad vṛṣabho jīradānū reto dadhāty oṣadhiṣu garbham.

- *Rgveda*, 5.83. 1

⁸³ *Nighantu*, 1.1.11

⁸⁴ *Gāvah bhūriśringā.* - *Rgveda*, 1.154. 6

⁸⁵ *Mātā rudrāṇām duhitā vasūnām svasādityānām amṛtasya nābhiḥ.*

pra nu vocām cikituse janāya mā gām anāgām aditīn vadhiṣṭa. - *Rgveda*, 8.101.15

⁸⁶ *Idā higauraditīrhi gauḥ sarasvatī hi gauḥ.* - *Śatapatha Brāhmaṇa*, 14.2.1.7

(iv) **Horse (*Aśva*)**

In Vedic verses the epithet *aśva* is used to describe the most important Vedic god, i.e., *Agni*. In such verses *Agni* is demonstrated as swift as a horse. According to Vedic seers, *Agni* is like a swift horse.

- The wise men worshipping it in the cosmic ocean of the firmament establish its two - fold light among the people of universe. May it, the messenger of Nature's bounties, possessed of swift flames, be superior to creatures of all regions.⁸⁷
- The dedicated devotees glorify that fire - divine, who is the showerer of blessings, the bearer of homage to divine powers, just as a horse bears the rider to his home.⁸⁸

In *Śatapatha Brāhmaṇa* *Agni* is mentioned as horse and also as white horse.⁸⁹ Basically, *Agni* is well known for carrying the food of all the deities.⁹⁰ Thus, *Agni* is called a bearer of homage to divine powers.

(v) **Vulture (*Grdhra*)**

In *Rgveda*, this epithet is used for *Bṛhaspati* and *Sūrya*, when they try to secure rain for the welfare of living creatures:

- As a spark or just a drop in the sky, he comes near the ocean, still looking at us with a vulture's eye. His lustre shines in its own bright splendour and as he shines high in the sky, he illuminates the regions below.⁹¹

It is noteworthy that many animals are taken as an epithet to gods. Vedic literature is woven in symbolic language. The names of the animals are taken for deities because of their attributes. It is quite clear that animals have their inevitable importance due to their special traits.

In this way, it is absolutely clear that the importance of animals is existing from ancient period. Animals are considered as wealth. They not just increase human wealth in all respect, but also they are the best friends of human beings. An instance is found in the famous epic *Raghuvamśa* of Kalidasa that birds share the sufferings or sorrow of human beings by their cries.

Animals are the best teachers of mankind. *Rāmāyaṇa*, *Mahābhārata*, *Pañcatantra*, etc. contain a great deal of stories of animals which reveal morals to mankind. In short, the role of animals in human life is highly important, so the several laws to protect animals can be advocated in the present time. Indeed protection of animals will definitely save the life of human beings.

⁸⁷ *Eṣa viśvānyabhyastu bhūmā devānām agniraratar jīrāśvah.* - *Rgveda*, 2.4.2

⁸⁸ *Vṛṣo agnih samidhyate 'śvo na devavāhanah.* - *Rgveda*, 3.27.14

⁸⁹ •*Aśvo ha vā eṣa agnih.* - *Śatapatha Brāhmaṇa*, 1.4.1.30

• *Agnirvā aśvah śveto.* - *Śatapatha Brāhmaṇa*, 3.6.2.5

⁹⁰ *Agnirvai devatānām mukham.* - *Śatapatha Brāhmaṇa*, 2.5.1.8

⁹¹ *Drapsaḥ samudram abhi yaj jigāti paśyan grdhrasya cakṣasā vidharman.*

Bhānuḥ śukrena śociṣā cakānas trīṭyē cakre rajasi priyāṇi. - *Rgveda*, 10.123.8

Conclusion

The phenomenal space given to animals in ancient Indian scriptures is not mere religion of ancient society, but animals were part of public policies of welfare as modern equipment which could sense any calamity to human race in advance. We have heard dogs, cats, cows, and horses saving their masters like the Hachiko dog in Japan or Chetak horse in India, but mankind has failed to further their research into their incredible sensibilities to forewarn disasters. In brief, this chapter opens vistas for further an idea to be taken over by scientists across the world.

Abstract

An absence of “coordination” and consequently of fitting “collaboration” exists in all disaster management institutions (National Disaster Management Authorities, State Disaster Management Authorities, District Disaster Management Authorities) because of which the lives and livelihood of individuals are in danger and become more powerless against calamities. The bungling and absence of administrative coordination pre- and post-floods, earthquakes and in numerous different catastrophes, brought about loss of lives concerning human resources, non-human resources, and financial misfortune, etc. Monetary misfortune could be recaptured; however, it is absurd to expect the misfortune of humans and non-humans (who cannot talk) to recover. The job of the state power is not to reject the minorities; it is to set up the general public at large (which incorporates every individual and non-person) to confront the difficulties of the disasters and to give medical aid with almost no terrible expectation towards a specific local area and to set them up for future catastrophes. The chapter centres around “methodical disappointment” of the state administration in the setting of disaster management and “rehashed disappointment” of administration at all degrees of government-assisted organisations because the absence of coordination before

and after normal disastrous catastrophes is the primary issue. Loss of lives of people and non-people has happened more in light of this “foundational and rehashed disappointment of administration” than in a disastrous event. The chapter depends on both primary and secondary data or information regarding the states Odisha and Jammu & Kashmir.

Keywords

Disaster Management · Coordination · Disaster Management Act 2005 · Institutions

Introduction

Any discourse on the governance imperatives of disaster mitigation gets embroiled in the institutional blame game or centre-state politics in a federal nation such as India. It has been difficult or even impossible to achieve a balanced understanding or the teamwork expected in a catastrophic situation. The Disaster Management Act 2005 appears to be just a skeletal reflection of the enormity of deep contingencies faced by institutions during a disaster, which leaves ample scope for them to act with indiscretion and also in isolation from others in the field. However, this situation is changing, and lately, a proactive role of courts has identified basic requirements (*Ramachandran vs District Collector Kottayam, 2015 WP (C) No. 11876 of 2015*), issued guidelines (*Swaraj Abhiyan vs Union Of India And Ors, 13 May, 2016, Writ Petition (C) No.857 of 2015*), and basic indicators, which institutions in disaster mitigation are mandated to follow and obey. If one goes through the history of repeated disasters and information on the devastatingly irresponsible administrative response, one would definitely ask the question whether institutions created under the Disaster Management Act 2005 are adequately prepared to work beyond the business as usual attitude of their insulated silos and segregated jurisdictional domain, which becomes deeper owing to their inability to collaborate and work in a more transdisciplinary environment of taking everyone together.

Institutional structures, skills, training and the traditional art of coordination are challenging targets to achieve in India. Institutions and stakeholders, which play a vital role in disaster governance in India, have no meaningful relationship amongst themselves, and even the institutional restructuring has not been as helpful as needed either. The Third Report of the Second Administrative Reforms Commission on Crisis Management (2006) identified key problems embedded within institutions, yet its recommendations continue to be side-lined. The federal and inter-district communication and coordination among stakeholders of disaster management seem slow, which results in disasters such as the floods we witnessed in the states of Jammu & Kashmir (J&K), Kerala, Odisha, Bihar, Uttarakhand, Tamil Nadu etc. The issue of federalism centres around disaster governance in this context.

In this situation, there is a need to re-examine the cycles of disaster governance. India, as a government state, plainly referenced the different capabilities under the

union list, state list, and concurrent list. These capabilities have been conveyed between the state government and central government, in which “disaster management and disaster governance” in a setting of floods, seismic tremors, typhoon, avalanches, torrential slides, etc., have not been referenced, and there is no circulation of obligations to oversee or administer these cataclysmic events. It has been expressed that disaster management is a state subject. Nonetheless, relegating explicit obligations and organising administrative instruments at an alternative degree of administration is vital.

With the drawing up of the National Disaster Management Act 2005, certain rules were arranged/laid out on how state and central governments can oversee catastrophes and administer during crises. However, two significant activity focuses passed up a great opportunity, i.e. “decentralisation and coordination” in disaster administration between state community workers and local officials, and at neighbourhood/ panchayats level networks with central government, are absent. No severe rules were outlined for the state, region, and nearby government to keep up with “coordination and participation” during a causality/casualty man-made or catastrophic event as it is a state subject. The central government has additionally not assumed any great part in that frame of mind among these institutions at the state/district/local level according to the previous encounters of disaster management.

In numerous disaster events such as the Ladakh floods in 2010, the Uttarakhand floods in 2013, the J&K floods of 2014, the Chennai floods of 2015 and the Kerala floods of 2018, no convenient reaction or readiness was seen, and there was likewise an absence of coordination between the centre-state agencies, between the military, the National Disaster Defence Response Force (NDRF), Coast Guards, neighbourhood police, and the State Disaster Management Authorities (SDMAs) and the District Disaster Management Authorities (DDMAs). Issues of provincial contrasts, between local issues and political contrasts were likewise seen and featured by the general population and media people. Because of these dangerous issues, the life and work of the humans, and non-humans during floods or any sort of calamities are more defenceless, horrible and full of fear. Under the Disaster Management Act 2005, the majority of the states have not even pre-arranged an essential disaster management plan. The greater part of the states have their executive disaster plan just on paper and not completely ready.

In the states that have do have plans, either those plans stay obsolete, non-executed, or disaster management specialists have an absence of information and skill in misfortune the board and are not working very well. The Odisha and Bihar models of catastrophe administration have been moderately effective with next to no capacity to support and archive the move made during the activities at each stage. Other than Odisha, the region and nearby specialists are not prepared to distribute the data to the networks, which are the people on call for cataclysmic events.

Following 70 years of freedom and two managerial changes, i.e. the first Administrative Reform Commission (ARC) and the second ARC, why are our state directors not in that frame of mind to facilitate with one another during normal devastating catastrophes to mutually deal with disasters? Why would that be a

foundational disappointment, and rehashed disappointment has been occurring? Why do our overseers have no dynamic power in setting up disaster administration and are absolutely reliant upon the central government? There is a need to address these disappointments in administration. As per research, it is written that and researcher quoted:

In the legislative federations, “the division of abilities was set in some kind of stone by identifying a rundown of strategy spaces over which the central government conceded a position to enact. Because of the government design of India, states have authoritative abilities to make regulations, yet during crises, the power is circulated according to the specific organisation’s range of abilities to oversee debacles. The connection between the state and the middle during crises of catastrophic events is more on salvage, help, and restoration instead of moderation and readiness. As well as appreciating distinguished powers, the public law-making bodies in these two alliances were allowed an unequivocal ‘matchless quality’ in those cases where any cross-over ought to happen.” (Alan Fenna, 2012 Chap. 47).

On account of disaster management, the job of communities is vital as they are people on call regarding any sort of catastrophe such as floods, tidal waves, tremors and twisters. The requirement for readiness and flexible working among them is vitally close to managerial/administrative coordination. The Hyogo Declaration of 2005 changed the talk from the previous to the last option. Sendai Framework 2015 has likewise settled the requirement for combining readiness with advancement, which brings the formative organisations and the fiasco the board offices close, covering, and cooperative. Unexpectedly an absence of coordination exists in federalism, which the nation of India has embraced (Basu, 2018).

The National Disaster Management Plan (NDMP) 2016 specifies coordination 106 times in 192 pages; however, a couple of organisations would research, contend and examine the coordination pre-catastrophe, post-catastrophe and during the catastrophe, which is amusing (mha.gov).

Explanations Behind the Disappointment in the Context of Inter-Agency Coordination: A Perspective from J&K and Orissa

During field work, researchers find many purposes behind the disappointing coordination in key disasters such as the Kashmir flood of 2014, the Orissa cyclones, the Kerala flood of 2018, and the Uttarakhand flood of 2013. Researchers recognised countless hindrances and difficulties in light of writing research, field perception and review. Apparently, there is no single variable that blocks or works with coordination.

The two locales affected by floods, specifically the Srinagar and Anantnag areas in J&K, have wide stream bowls and other water bodies such as lakes and wetlands. The flood of 2014 had occurred because of an authoritative lack of care and human insatiability, defilement and developments on riverbeds or developing agriculture on riverbeds or water bodies. One regulatory authority informed the researchers that

individuals are still wrongfully possessing the place where there are water bodies even after organisations see them; individuals as a rule disregard these notifications and step by step expand their development or agricultural land region in these areas — there is no enforcement of regulation at ground level.

During the researcher's field assessment, it was observed that institutions of disaster management are working from their comfortable workplaces. The execution of strategies and plans are just on paper, field work by researchers and pictures taken while doing the review clearly show the earnestness and attitudinal conduct changes in their work and individuals' obliviousness towards the security of regular assets. Individuals' cooperation is exceptionally less in all parts of formative exercises in the state, particularly in Kashmir Valley, despite the fact that people's contribution to the turn of events and the execution of assets is critical.

As per hands-on work by the researcher, meetings with authorities likewise reveal that in spite of being powerless against catastrophic events, J&K continues to have one of the lowest densities of weather condition stations in the country. There are just seven weather condition stations in the whole valley and six in the Jammu district to handle meetings and conversations with directors.

The disasters in both the states J&K and Odisha are a direct result of the "state's ecological debasement," which has helped a great deal in setting off these disasters. As per meetings and conversations with the authorities, the 2014 floods had come about in view of one of the underlying drivers, the absence of dependable data on climate, which was nevertheless answerable for the gigantic death toll and damage to properties in the case of flooding, avalanches and torrential landslides in the state.

During the hands-on work the analyst broke down that there was an absence of assets in setting to disaster management is one issue, yet then again assuming not many assets are accessible to deal with any dangers, the absence of ability is one more enormous issue in setting to calamity the board.

As per interviews with disaster management experts in the state of J&K (which is presently Union Territory, after repeal of Article 370 and 35A/5 August 2019) and the Public Health Engineering department (PHE), the Irrigation and Flood Control Department, they uncovered that digging and desilting needed more men and hardware, which were lacking within the framework; however, an honest effort is being made to clean the water bodies. Under digging, against 16.36 lac cumec, 8.53 lacs cumec of material has been dug out up to that point (2017–2018). From that point onward, no report or information has been disclosed.

Another point I might want to make here is about the "trust" of individuals of J&K; they have no trust in administrative notifications and alerts, then again, interviews with officials showed that they had given an warning to individuals through the press, electronic media, and through different non-governmental organisations (NGOs) that are working for disaster management; however, individuals had not expected surges of such a colossal extent. The collaboration of researchers with nearby communities on the opposite side totally denied any advance notice by the administration using any and all means. It shows us that there is no trust and coordination between the public and the managerial framework.

When a researcher looked at the two states J&K and Odisha concerning store use and execution of different tasks, the Comptroller Auditor General (CAG) reports for the two states showed that ventures are not carried out productively regardless of using crores of rupees and catastrophe moderation, and limit building systems at a local area level remained practically missing. Likewise, the absence of coordination between divisions brought about episodes of additional consumption and overabundance.

The researcher likewise found while doing hands-on work that the two states have been compromised by the disaster management specialists; in particular, the SDMA and DDMA at state and region levels are not following a solid system to prevent disasters, but rather they are dealing with catastrophe reaction and post-disaster help. Likewise, the state Odisha has recurrent disasters, and it is more ready and has a powerful component. One more issue lies in the design of Disaster Management and it is that they have organised impromptu individuals or have selected individuals from inside the organisation to take care of Disaster Management or generally the Revenue Department/Secretary. There is an absence of impressive skills in Disaster Management in regions such as Srinagar, Anantnag, Puri, and Khordha. There is an inadequate Institutional plan: if one reads the 2005 Act, full-time experts have not been locked in according to the rules, which is a main driver of the Indian disaster managerial framework being as yet deficient with regard to disaster mitigation and management.

During hands-on work in the valley, the analyst likewise saw a few stunning results of the unrestrained extension of the travel industry around Dal lake. Most importantly, the major legitimate system that ties each and every sectoral regulation to the life and security of people and non-people of J&K that is calamity the board Act 2005 was not executed and was not set up at that time (flood 2014).

One more exemplary illustration of the absence of coordination is found in the inclusion in the news of the High Court hearing on the Chennai flood, covered by PTI, 22 January 2018: the news report portrayed how the high court mediated to relieve the disaster in the state. As state organisations did not have dexterity and correspondence among themselves. Indeed, even the coordination between the naval force, armed forces and coast monitors was lacking, and furthermore the behaviour of nearby individuals with the help of merchants/agencies was bad. Hence, the backer A.P. Suryaprakasam moved the court, chasing “security” to help “laborers by framing miniature level overseeing councils following charges that administering party laborers and local people were bothering alleviation faculty conveying material for flood casualties.”

“Madras High Court today voiced concern over lack of coordination among agencies in the unprecedented floods in the city.

“What concerns (us) is there seems to be little lack of coordination among agencies in distributing relief materials,” said the first bench comprising Chief Justice Sanjay Kishan Kaul and Justice Pushpa Satyanarayana. Available as Public Interest Litigation (PIL) by advocate A. P. Suryaprakasam seeking “protection” for aid workers by forming micro-level managing committees following charges that ruling party workers and locals were

harassing relief personnel carrying material for flood victims.” (<https://www.thehindubusinessline.com>. Published by PTI, 11 December 2015, Updated PTI, 22 January, 2018)

Solutions for Work on the Coordination Among Different Institutions at Various Levels are as per the Following: A Viewpoint from J&K and Odisha.

A few planning organisations should be there to facilitate a more synergetic methodology for regulatory viability in disaster management in India. The meeting closed with a current individual from National Disaster Management Authority (NDMA), Kamal Kishore, by the researcher in his office (Year-2019). He referred to better coordination in the utilisation of innovation. As indicated by him, innovation (technology) is a more creative method of helping coordination.

Direction and administration likewise influence the coordination cycle in an establishment. Nothing is a higher priority than institutions. That is the reason why we make them; they can prompt uncommon changes in a disaster, the board situation of a dynamic authority and participatory dynamic cycle. Among departmental coordination, we have an enormous number of divisions and organisational bodies; if every one of these can be consolidated together, a brief reaction can be accomplished. He said that capacity building is one assignment for building more powerful foundations of catastrophe for the board. There is a need to make institutions of disaster the board more skilled and prepared for taking care of disasters. The ability of establishments is required in a disaster between the management and relief, and it is likewise connected to the designation, correspondence, direction, and between-organisation coordination in a foundation (Paton & Jackson, 2002).

In inter-agency coordination or institutional coordination, there is a requirement for clear instructions, jobs, obligations and connections between all degrees of government. In setting the authority for disaster management, the neighbourhood level administration building is an unquestionable requirement to settle on speedy and fitting choices when required (Paton & Jackson, 2002). In emerging nations such as India, disaster events require phenomenal administrative capacity, as these events overpower neighbourhood abilities and nearby networks. The absolute requirement of leaders at the public and state level, subsequently, is to adjust and reconstruct the crisis framework and plan to limit the detrimental impacts of the disaster in the briefest conceivable time (Paton & Jackson, 2002).

Likewise, there is an absence of proper power and obligation with public, state, regional, and neighbourhood level establishments (Disaster Management Act 2005) to answer in a crisis and under emergency circumstances. In that capacity, no plans are accessible for coordination between partners at the public, state, region, and neighbourhood levels. All are working in restricted ways with their locale (Disaster Management Act 2005). Additionally, there is no different service (separate ministry) that cares for disaster management solely in India.

During the hands-on work by researchers on disasters the board authorities such as Odisha State Disaster Management Authority (OSDMA), J&K State Disaster

Management Authority (JKSDMA) and DDMAs, the analyst found that all authorities concurred and said that opportune/timely coordination/better coordination between divisions/organisations have helped in saving lives, method for business and property. According to them, designs of the division, jobs, obligations, unbending administrative methodology, absence of trust, independence, credit, absence of assets and mentality prevents coordination among individuals/decision creators in an establishment of disaster the board.

At the point when the researcher asked them, "What can help coordination," they answered diversely according to their own involvement in the idea of work and establishments. They replied that mindfulness, preparing, a reasonable job and obligations with an adaptable framework can help to improve coordination. Likewise, according to the authorities we talked to, the principal challenge is the foundation of an exact coordination component between various legislatures and NGOs working at all levels. Coordination between the Ministry of Home Affairs, the NDMA, the SDMA and the DDMA should be fortified.

The researcher had an interview and a 1-h conversation with K. M. Singh, ex-official from the NDMA about the issue of institutional coordination in disaster management in India. K. M. Singh remarked that in an Uttarakhand flood of 2013, institutional coordination was seen; however, at that time no institutional component was set up by the Uttarakhand government. After this misfortune had occurred, the central power NDMA produced more NDRF Battalions. They began the NDRF in the 2008 with eight battalions. These battalions helped individuals during the Kosi River Flood in Bihar, the main significant flood dealt with by the NDRF. The fact that time by NDRF group makes around one lakh individuals were evacuated. That was a gigantic flood, and the NDRF accomplished exceptional work.

The Chief Minister of Bihar State, during that period, praised the NDRF, and proposed having NDRF battalions in Bihar too. The NDMA consented to that; however, the issue of the land took 3 months to lay out the power's ninth battalion NDRF, Bihata Patna, Bihar. The land was liberated from the cost from the state government by the NDMA to lay out NDRF Battalions. This shows the Bihar state's devotion and soul regarding keeping people and non-people safe from future catastrophes.

Additionally, Andhra Pradesh gave land and laid out the tenth battalion of the NDRF, ANU grounds, Nagarjuna, Guntur (AP). Presently, India has 12 NDRF battalions spread all over the country. The Odisha state also have one in Cuttack (3rd Battalion NDRF), the most leading state in context to disaster management and mitigation. The Odisha state organisation is executing orders at various levels and has outlined panels at state level, district level and town level on regular disasters. They have gatherings and meet at whatever point required. The designs for disaster management are amended yearly according to the changing idea of disasters, yet the issue of ground-level coordination in all actuality does likewise exist in Odisha.

K. M. Singh expressed that on account of Uttarakhand, the state government is not responsive and dynamic in setting to catastrophe the board. From 2009 onwards, the NDMA and central specialists in disaster management have been requesting the space, yet they were unable to give the land for laying out NDRF battalions (2019).

At the point when the Uttarakhand misfortune occurred in 2013, an enormous scope of decimation occurred. Indeed, even after that misfortune, no land has been given by the state government to the foundation of an NDRF battalion. Thus, the NDMA has land issues with the Uttarakhand state. The between-state struggle for land exists is the reason why the NDMA was unable to do all that it really needed to do.

In spite of the fact that we all realise that at the moment of a disaster, the fast responder is the NDRF, there is no question that the local area is likewise the specialist on call according to earlier research and scientists. The territory of Uttarakhand actually experiences various catastrophes; however no one makes a big deal out of it. An NMDA ex-member discussed the horizontal and vertical coordination in an organisation of disaster management. On account of Uttarakhand, even pre-disaster coordination was terrible, although vertical coordination was great, i.e. coordination at the central, state, and district levels. Level coordination exists in the state of Uttarakhand in the different state associations/departments that were deficient.

According to his experience, the J&K flood of 2014 was dealt with in a normal manner, in spite of the fact that organisations guaranteed that they dealt with it, in the best case scenario. On account of J&K, the board organisations and partners have no record accessibility. K. M. Singh said that in the case of Uttarakhand, the state government is not responsive and active in context to disaster management. In the year 2009 onwards, NDMA and central authorities of disaster management are asking to provide land, but still, the state could not give the land to establish NDRF battalions. When the Uttarakhand tragedy happened in 2013, a large-scale devastation occurred. Even after that tragedy, no land has been provided by the state government for the establishment of NDRF battalion. Thus, the NDMA has land issues with the Uttarakhand state. The centre-state conflict problems for land exist due to which NDMA could not do all that it actually wanted to do. Towards the end of the conversation, K M Singh referenced that local area support is vital in calamity the board, and they go about as essential facilitators whenever prepared and made mindful well about disasters.

In the case of Orissa, in the year 2013 Cyclonic Storm Phailin, was best taken care of and was an illustration of between-department coordination. He said that it was better coordination for such a long distance as far as anyone is concerned. The Indian Meteorological Department assumed a critical part during the 2013 Cyclonic Storm Phailin. The territory of Odisha was ready, and had promptly accessible structures/schools for people's evacuation. The state government knew which town region should be emptied. State and nearby government panchayats facilitated through microphones, speakers, SMS and let people know whether you get by, property and other materialistic things will return. This sort of coordination had been seen before at the time of the 2013 cyclone, also in Odisha. At the point when the state received the alerts, each office with food, medication, wellbeing, water, fire, etc., prepared and persuaded individuals at their level to leave their places and move to more secure spots. A few losses happened around then. The mind boggling position and coordination throughout the entire existence of the disaster management in India

were seen around then. Individuals abroad were interested in becoming aware of how Odisha did it so well.

The best of district-level coordination, which is exemplary, can be upgraded by the state administration by doing mock drills and gatherings at regular intervals. One more issue that was examined by K. M. Singh during the interview and discussion that if in the current scenario, the problem of coordination failure arises, it is because of political interference to disaster management institutions. K. M. Singh additionally referenced about the Kerala flood 2018, the most obviously terrible type of coordination among every single level power. Data dispersal is fundamental, that was inadequate. The way in which great coordination has an effect can be found on account of the Odisha state government.

After 2014, all individuals from the NDMA were approached to leave, and new individuals were selected because of the changing idea of legislative issues in India. The Failure of disaster management authorities and coordination began around then. K. M. Singh honestly says that SDMAs and DDMAAs are not useful at ground levels except for in a few states. Although the researcher likewise concurred, and additionally noticed something similar during her hands-on work; however, Odisha is doing great when contrasted with J&K. He said that the Bihar State Disaster Management Authority is ideal and practical in nature. He said that disaster management needs powerful characters, yet individuals who are working in a fiasco the board are not specialists and dynamic except for a couple of states such as Bihar and presumably Odisha.

As indicated by K. M. Singh, the National Disaster Management Authority is in an exceptionally low position at the present moment. According to K. M. Singh, National Disaster Management Authority is very down right now. The current regime removed the rank system, which makes a difference in disaster management functioning. All NDMA members are equal to the secretary, and now the secretary governs disaster management. All the perks and powers are gone. They have demolished the NDMA ranking and power. All NDMA individuals are equivalent to the secretary, and presently the secretary oversees disaster management. Every one of the advantages and powers are gone. They have destroyed the NDMA's position and power. K. M. Singh said that there are gaps and deficiencies in institutional courses of action, strategy, plan definition, as well as the execution of pre-disaster estimates in India.

To put it plainly, ironically and tragically, in J&K catastrophe the board authoritative framework reactions to many inquiries connected with arrangements, readiness, alleviation, the management of water bodies, wetlands, water channels, data spread to metropolitan and panchayat specialists, early admonition framework, jobs and obligations of the state disaster management specialists and region fiasco the board specialists, issues of coordination, the government's prompt help measures etc., has just repeated that the J&K flood was unprecedented; however, the report shows that the state is not being administered consistently with existing regulations and the moral edge, which considers human and non-human residences. Then again, the Odisha government on catastrophe the board and moderation made a colossal improvement beginning at around the time of the 1999 Super Cyclone; they have gained an example from each year of floods and twisters and are making

arrangements according to that, making networks strong by giving them preparation and by making them mindful about disasters. The state organisations are becoming well organised for future disasters and are ideally preparing and making arrangements for human and non-human residences.

In a meeting with the OSDMA authorities, it was found that Odisha likewise needs coordination at the field level. The authority said that they have tension from the central government for executing orders; however, making arrangements for building debacle though framework exists with the framework. For instance, telecom towers were made on the top of the house structures. During the twister-cyclone, these pinnacles fell and brought about the deficiency of the houses/infrastructure and loss of life. He additionally referenced in his conversation that individuals working within their specialties are restricted to issues within those specialisations. The sanctioning of specialists is an issue, and it is not plainly referenced in the Disaster Management Act of 2005. The role of Panchayats and Urban local bodies is not defined or clearly stated in the Disaster Management Act of 2005. Due to which enforcement of orders is not possible. Corrective activity for SDMAs, DDMAs isn't there in that frame of mind because of which managerial failure exists. The absence of assets, cash, and labour, and mental ability generally exist with the divisions and institutions. Yet, in addition, simultaneously, there is an absence of order, control and innovation too within the managerial framework.

Conclusion

The actual idea of an institution is attached in its capacity to arrange its human and material assets. Douglass C. North, in 1990 wrote in his book that foundations decrease vulnerability in the existence of individuals by giving design to daily existence. Be that as it may, when we see recent disasters in India, vulnerability was there among the two establishments and individuals. This implies that institutions are not aiding that mind-setting to disasters owing to an absence of a mix of expertise, system, assets and coordination.

At the point when there are various kinds of partners from various foundations/ backgrounds with various areas of interest (interdisciplinary methodology/subjects – software engineering, association hypothesis, science management, financial matters and brain research, etc.) who are working at various levels of organisations to serve society, coordination seems to become an integral factor. During disasters, they all need to team up and approach them together to facilitate and to help individuals. To unite and work in a team leaving behind the background and departments from where they belong requires coordination, because these are all separate/_multiple actors from different areas, entering an interdisciplinary field of disasters and disaster management. Likewise, every actor has various exercises to do, and to facilitate movements of every kind simultaneously and under all circumstances is an incredible test. Here, coordination is needed or lacking in the vast majority of catastrophic events (Malone, 1988). The coordination hypothesis goes under interdisciplinary fields. It investigates the normal issues of numerous actors, which were viewed as issues in various fields (Malone, 1988).

Abstract

This chapter explores the urban expansion in Indian coastal states since independence and how factors like population pressure, economic globalization, and natural hazards turned these states more vulnerable to disasters. The study focuses on urban density, coastal zone, and urban infrastructure. East coast of India is more prone to cyclones, whereas the west coast faces more threats of floods, erosion, and irregular rainfall leading to droughts/floods. This leads to aggravate the mitigation strategies and consequences of disasters on dense urban settlements that affect adaptation strategies. The peninsular coastal region has experienced rapid urbanization with an unequal spatial distribution pattern, particularly in Kerala. Urban

expansion is projected to continue in the coming years that brought more area under disaster threats. States like Goa (in percentage) and Maharashtra (absolute number) have the highest level of urbanization in the country. Each coastal city in India is either facing challenges of infrastructure or basic services. The environmental threats to these coastal regions cannot be ignored. Keeping physical conditions of coastal belt in consideration, the coastal region is in various developing stages from Utkal coast to Kathiawar peninsula. This study emphasizes urban agglomeration and infrastructural development since globalization. Demographic change clearly marked the dividing line between coastal and inland states of India, which is also not untouched by disasters. Furthermore, the role of artificial intelligence (AI) cannot be ignored after Odisha's (1999) most destructive super cyclone. In this chapter, an attempt is made to correlate the lives and livelihood of coastal people across the urban region.

Keywords

Globalization · Urban agglomeration · Demographic change · Artificial intelligence · Hazard

Introduction

The total length of the ocean is 1,634,701 km, and more than 39% of people live within 100 km of the coastal zone. More than 600 million people live extensively in coastal areas around the world with an elevation of <10 m, of which 360 million reside in urban areas. The world's 10% of population inhabit low-altitude coastal zone making their lives and livelihood more vulnerable to natural hazards. Low-altitude coastal zones account only 2% of the world's land area that hold 10% of world's population and 13% of urban occupants. Million-plus cities, accounting for 75% of world's share, have their largest city close to coastal areas with <10 m elevation.

India's 7516.6 km-long coastline is supporting about 35% of its population within range of 100 km from the coast. India's share in the world's coastline is less than 0.25%, which is inhabited by 211.93 million people. With 640 districts in India, 76 coastal districts have 17% of its share in national population, and within 50 km of its coastline, nearly 250 million people reside. Seventy-seven cities come under the nine coastal states and four UTs, which comprise largest and most dense urban agglomerations in India.

Study Area

India's total coastline is about 7516.6 km, of which 5437 km are the mainland coast and the rest in the island territories of this subcontinent. Its share in the world's coastline is $<0.25\%$, but as a share of population, it counts 17% of the world's

population. Taking these facts into account, internationally the Indian coastline is the most densely populated (Sankhua 2012).

According to census 2011, 377.1 million people in India reside in urban areas. Forty-eight percent of India's population have lived in 2661 towns of coastal urban areas in 13 states and UTs (Sibananda and Vijaya 2014). 64.45% of people from slum areas live in poverty in nine coastal states. These areas are more vulnerable as exposed to frequent occurrence of cyclones, sea storms, tsunamis, and environmental hazards. People are more exposed to hazard and disasters if they live in longer coastline and lowlands with more dense population than those living in shorter coastline and less people in lowlands.

Data and Methodology

Nine states along with their coastal districts have been selected for the study, and data was acquired from the 2011 census of India. Governmental and different organizational reports were cited for the current situation in coastal districts of India. The decadal demographic database of census of India and the master plan of coastal cities were taken into account. ArcGIS 9.3 was used to acquire image processing and create the coastal district GIS database. The whole paper is based on secondary sources that include literature surveys.

The main objective of the study is to find the changing scenario of Indian coastal cities in terms of urbanization. How the continuous growth of population pressure and natural hazards has harmful effects on urban density from the disaster angle. The study also deals with the consequences of disasters on densely populated urban settlements.

The eastern side, known as Utkal and Coromandel Coast, has four coastal states of West Bengal, Odisha, Andhra Pradesh, and Tamil Nadu. The western side of Konkan and coastal belt has states of Gujarat, Maharashtra, Goa, Karnataka, and Kerala. Pondicherry, Andaman, and Nicobar Islands on the east coast represent as the union territories, while on the west coast Daman, Diu, and Lakshadweep Islands represent the same. These nine coastal states and three UTs constitute 1,395,933.69 km² area out of which 558,673.93 km² fall under coastal area, which includes 76 coastal districts. According to the 2011 census, there are 486 towns along the coastal region with 41.7 million inhabitants which constitute 20.7% of the total coastal population (GOI 2019-ENCORE).

Census of India 2011 shows that Kerala has seven million-plus cities (equal to UP) followed by Gujarat four million-plus cities, Maharashtra and Andhra Pradesh two each, and West Bengal and Tamil Nadu one each million-plus cities in the coastal plains. Malappuram, Thrissur, Kannur, Kollam, Kozhikode, and Thiruvananthapuram were added in 2011 census in Kerala. Vasai-Virar Maharashtra and Tiruchirappalli in Tamil Nadu added to the coastal plains in 2011 as well. These cities are represented by coastal climate (Table 1).

The above table shows that the districts of coastal India and its urban population are highly exposed to severe cyclones, erratic rainfall, storms, etc. The most

The Challenged Coast of India, a report, by BNHS, NCPC, PondyCAN and TISS a Discussion Document, 1st Edition, Hyderabad, October 2012 (Ahana et al. 2012)

urbanized large states of India which include Tamil Nadu, Maharashtra, and Andhra Pradesh are more prone to cyclones. Most of their million-plus cities are located in the coastal zone as compared to the total million-plus cities. The population density of these coastal states in class I to class III towns is also very high.

Coastal Settlements

As far as lengths of the coastline are concerned, it occupies 4521.5 km in the east coast and 3009.5 km in the west coasts of mainland India with a share of population of 102.4 million and 87.4 million, respectively. The length of the west coast of India is comparatively longer than the east coast. The Indian coastlines have the largest urban agglomerations along with 76 cities and towns. Since 1901, Kolkata (then Calcutta) and later Mumbai (Bombay) are the two megacities of coastal India. Chennai, Tuticorin, Cuddalore, Visakhapatnam, and Puducherry are major cities of the east coast, while Kochi, Mangalore, and Surat on the west coast are prominent cities. These port cities are emerging as industrial hubs and turning into large urban agglomerations.

As far as fishing villages are concerned, there are 3288 marine fishing villages distributed in east and west of India. Tamil Nadu is at the top as far as marine fishers (8.02 lakh) are concerned, followed by West Bengal (6.34 lakh) and Kerala (6.10 lakh). It is difficult to apply the concept of primacy at the national level (CRZN 1991). To some extent, it is applicable to the state of West Bengal where primacy still exists.

Coastal Livelihoods

CMFRI2 conducted marine fisheries census in 2010, which shows 9 maritime states and union territories have 1511 marine fish landing centers. The population of marine fishermen is approximately 4 million, of which 61% of the fishermen live in the below poverty-level category (GOI 2019-ENCORE). Salt production is the second important coastal livelihood in India. With an average annual production of about 157 lakh tons, India's salt production is the third largest in the world. The contribution of sea salt making is up approximately 70% of overall salt production. The leading states of sea salt production are Gujarat and Tamil Nadu (CMFRI 2016–17).

Coastal States of India

The Western Coast Region

The west coast of India is characterized by estuaries with few beaches. The length of the west coast is 3009.5 km (including the UT of Lakshadweep) with a population of

87.4 million. The density of this region is 119 km^2 . The west coast of India is vulnerable to erosion, coastal flooding, storm surge, and pollution.

Gujarat

The coastal regions of Gujarat, geographically, can be divided into five regions: (i) the Rann of Kachchh, (ii) the Gulf of Kachchh, (iii) the Gulf of Khambhat, (iv) the Saurashtra Coast, and (v) the South Gujarat coast (CRZ 1991). The coastal area of Gujarat including the Rann of Kachchh is the largest in the country. Gujarat has the longest coastline of 1214.7 km in India with an area of $1,96,024 \text{ km}^2$. The state has population density of $308/\text{km}^2$ (2011 census). There are 17 coastal districts out of 33 districts of Gujarat.

Maharashtra

As far as size and population are concerned, Maharashtra is the third largest state in the country. The 652.6 km-long indented coastline of the state is geographically depicted by beaches, estuaries, and mangrove patches. The state's coastal belt known as Konkan coast comprises Thane, Raigad, Greater Mumbai, Mumbai, Ratnagiri, and Sindhudurg districts. According to the 2011 census, state density is 365 per km^2 , whereas Mumbai city's density is $20,038 \text{ per km}^2$; the suburban of Mumbai is quite dense with $20,925 \text{ per km}^2$.

Goa

The third state in Konkan coast is Goa, which is small in area (3072 km^2) but rich in minerals. Goa has the highest level of urbanization with 62.17% of its population living in urban areas. With a coastline of 131 km, Goa coast is famous for its beautiful pocket beaches, cliffs, estuaries, and bays.

Karnataka

Karnataka lies to the south of Goa; it is the eighth largest Indian state by area ($191,791 \text{ km}^2$) and has a coastline of 280 km. The coastal zone of Karnataka is narrow except around estuaries. Only three districts of the state are bordered by the Arabian Sea. Only 4.7 million people live in the coastal area of Karnataka, which is quite low as compared to the big states of Southern India.

Kerala

The state is characterized by Malabar coast with an area of $38,863 \text{ km}^2$. Kerala has 9 coastal districts with 33.38 million people. The elongated coastline of the state is 569.7 km long; its width varies from 11 to 121 km from north to south. As compared to Mangalore coast, the Kerala coast is a submergent one. According to an estimate, Kerala's 30 km of coastal belt is highly exposed to erosion and 21 km under accretion. Seawall plays an important role for protecting Kerala's approximately 360 km (63%) of the coastline. The entire coastal belt is characterized by its high population density, which is $1074 \text{ persons/km}^2$. The whole state is known for its urban spheres resulting in seven million-plus cities equivalent to Uttar Pradesh (ISRO 2012a, b).

The Eastern Coast Region

The eastern coast region differs from the west coast having a large number of deltas built by perennial (Himalayan origin) and non-perennial (peninsular origin) rivers flowing into the Bay of Bengal. The total length of this coastal region is 4521.5 km (including the UT of Andaman and Nicobar Island) with 109.12 million people. The region is more densely populated with a density of 158 km². The eastern coast is more prone to tropical cyclones, sea-level rise, tsunamis, and coastal pollution.

Tamil Nadu

In terms of area, it holds the 11th position in India and seventh most populous state. After Goa and Mizoram, Tamil Nadu is India's most urbanized (48.45%) state. The state has 13 districts with coastal boundaries. The coast of Tamil Nadu is approximately 906.9 km long with a population of 33.38 million. The state's position in sea salt production is second after Gujarat.

Puducherry

Puducherry is a union territory of India consisting of four enclaves. Earlier it was a part of French India. Karaikal, Yanam, and Mahé are other enclaves in Tamil Nadu, Andhra Pradesh, and Kerala, respectively. The territory has a total area of 490 km²: Puducherry 294 km², Karaikal 157 km², Mahé 9 km², and Yanam 30 km². In general, Puducherry has a coastline of 30 km of which 9.5 km is undergoing severe erosion.

Andhra Pradesh

According to the 2011 census, Andhra Pradesh is India's fourth largest state in terms of area and fifth populous state. It has a coastline of 973.7 km. The coastal area accounts for 33.6 million people with density of 337 km². The coastline of the state in south of Pulicat lake is indentation only; famous for its freshwater, Kolleru lake lies between Godavari and Krishna deltas (CRZ 1991).

Odisha

Odisha (Orissa) is 11th populous and 9th in terms of area. The state has share of 4.74% with an area of 1, 55,707 km² in Indian territory. The coastline of the state is 476.4 km facing Bay of Bengal. The Orissa coast is drained by two major river systems, namely, Mahanadi and Brahmani-Baitarani rivers. Both of these rivers form extensive deltas. The coastal region is exposed to severe cyclones (October, 1999 super cyclone). The Chilika lagoon is not only the state's largest natural water body but the country as a whole.

West Bengal

West Bengal with its unique physical features from mountains to plain spreads over 88,752 km². This second most densely populated state is fourth in population holding. The state's coastline is of about 157.5 km with a population of

29.28 million. West Bengal's southern part is a delta region with a density of 1333 km² per person. The coast represents a typical bird foot deltaic strip with a density of 1333 km² per person with almost flat terrain. The Hooghly river, which is a tributary of Ganga river, forms the most important drainage system of the entire state.

Metro Cities, Class I and Class II Towns in the Coastal Area

According to the 2011 census, 42 towns are classified as class I towns out of 486 towns that have a population of more than one lakh people. Class II with 50,000 to 99,999 persons and class III with 20,000 to 49,999 people have 48 and 129 towns, respectively. Of the total population of these coastal states that is 560.74 million, 211.93 million people live in coastal districts, which accounts for 37.8%.

Population of these coastal states is 560.74 million, which is 46.34% of total population of India. As far as populations of coastal districts are concerned, 211.93 million constitute the 17.5% of the coastal states (CPCB 2010).

Processes of Coastal Urbanization

A long time ago, all the great cities of today were born as villages or towns. They grew over decades, centuries, or millennia. Thousands of fisherman's villages have now become giant cities. Coastal urban centers are home to almost three billion people around the world and are experiencing unprecedented growth. Much of this growth occurs in developing countries due to the growing population.

It should be experiential that coastal urbanization is unequally located along the shore. The most appropriate system of urbanization of the coastal regions is the "pole and corridor system" of growth. Large coastal cities form the poles of this system, and corridors are formed by the remaining part of the elongated marine regions with a series of small urban centers, situated along the coastline.

Colonization and Coastal Urbanization

For thousands of years, the Indian Ocean region and the entire coastal region in general have been an important seat of civilization. There has been a long interaction of society with the coastal environment, particularly in India. Cities and ports, such as Mumbai (Bombay), Kolkata (Calcutta), Chennai (Madras), Diu, Surat, Goa, and Cochin, were established and developed by the Europeans initially to facilitate their commercial interests. This was used ultimately to enforce industrial and monopolistic capitalism, which later developed in the shape of large towns and cities (Table 2).

Table 2 Growth of the urban population in India (population in millions)

Year	1951	1961	1971	1981	1991	2001	2011	2019 ^a
Total population	361.09	439.24	548.16	683.33	846.42	1028.74	1210.19	1366.41
Urban population	62.44	78.94	109.11	159.46	217.55	285.35	377.1	471.03
Area in sq km				52,390.63	63,832.10	78,199.42	102,252.00

The Port Cities in the Region

The 11 coastal cities out of 16, which have more than a million populations, namely, Bombay, Calcutta, Cochin, Madras, Trivandrum, and Visakhapatnam.

Settlement

Approximately, a quarter of the India's population lives in the coastal belt. According to the 2011 census, 42 coastal towns fall under the class I towns. In the coming years, this population is likely to grow with a faster rate. The region is also characterized by 27 million-plus cities. This coastal belt is characterized by cities, towns, large metropolitan towns, million cities, and urban agglomeration. The settlements of these coastal regions are rural in character. Most of the inhabitants are involved in primary activities like fishing, agricultural, some in cottage industries, etc.

Coastal Regulation Zone (CRZ)

The Environment (Protection) Act of 1986, under parliament, has the objective to provide legal framework to protect our environment. The Section 3 (3) of this act gives power to the central government to establish authorities over it. This empowers the authorities to regulate coastal activities within a 500 m coast zone, which is further divided broadly into four zones as ecologically sensitive, built-up, rural, and islands areas (Marale and Mishra 2011).

Further, they are divided into four main broad domains as below:

CRZ-I (ecologically sensitive areas), there are restriction and prohibition of most of the activities in this ecologically sensitive ecosystem/zone.

CRZ-II (built-up areas), under certain conditions, development and construction activities are permitted.

CRZ-III (rural areas), limited activities are allowed in this undeveloped area.

CRZ-IV (islands), no construction activities are permitted.

The notification of 1991 prevents, restricts, and controls development activities from the high tide line along the coasts up to 500 m distance. The government of India in National Environment Policy, 2005, envisaged a vision of long-term management of coastal and marine areas. Twelve critically vulnerable coastal areas (CVCAs) have been identified by CRZ in coastal belt along with wetlands. India's coastline spread in 76 districts of 9 states, and 4 UTs accommodate 14.2% of its total population (GOI 2019-ENCORE). The coastal development in India can be best explained with the emergence of cities, towns, million cities, and ports along with SEZ, IT parks, economic hub, and marine fish centers.

The land area of the coastal region is shrinking not only due to the high concentration of population but also the development of industries. Not only garbage generated by these cities but effluent discharge, municipal sewage, chocking of rivers, desilting of drain, and recreational activities at beaches are immensely affecting our coastal environment.

The economic infrastructure in coastal region has significant share, not only in import-based industries but in petroleum industries as well. These are spread across 13 major and 138 minor port and 76 proposed ports with large-scale industrial units in 76 coastal districts. Coastal fishing provides employment to almost a million people, and the other 1.2 million people are engaged in postharvest fishery sectors. Rapid growth of population leads to expansion of urban fringe areas. Further this led to rapid industrialization, transportation, rapacious use of resources, excess in marine fishing, and coastal and seabed mining. The setting up of special economic zones (SEZs) has led to increased demand for energy, oil, gas, and infrastructure, hampering the wise use of natural resources to a large extent (Table 3).

Flood, Cyclones, and Other Events

The Indian coastal zone, particularly eastern coast, is exposed to several weather events like tsunami and cyclones. On an average, occurrence of nine cyclones per year leads to damage to lives and loss of property.

Between 1877 and 2005, the east coast of India has experienced a total of 283 cyclones within 50 km of its wide strip; on the contrary, west coast faced fewer cyclones, a total of 35 cyclones.

Nineteen severe cyclonic storms caused the human causality of more than 10,000 lives. The super cyclone of Odisha in 1999 resulted in enormous damage to property and massive loss of lives (>30,000 human lives). Similarly, the torrential rain in Mumbai in a single day of July 2005, which received a record 944 millimeters (mm) of rainfall, has created havoc among people (Sibananda and Vijaya 2014).

Around 12,388 people lost their lives and caused damage of \$32,615 million during 1999 to 2020. Bay of Bengal and the Arabian Sea accounted for only 7% of the world's cyclones which have severe impact on coastal districts and several major cities in the country. During the above period, Odisha coast witnessed 97 cyclones, followed by 79 cyclones in Andhra Pradesh, 58 in Tamil Nadu, 48 in West Bengal, 22 in Gujarat, 7 each in Maharashtra/Goa, and 2 in Kerala. In the last two decades, cyclones have 15% of its share in total natural disaster in India.

Purba Medinipur is the most vulnerable district of West Bengal in terms of occurrence of cyclones. The Sundarbans saw two cyclones Yaas and Jawad in 2021. The region has witnessed the devastation done by cyclone Aila in 2009. Baleshwar in Odisha is the most vulnerable district in severe cyclone category. In its third year in a row, Odisha witnessed a pre-monsoon cyclone after Amphan and Fani. Yaas has made landfall in Odisha's Bhadrak district in 2021. It has faced severe cyclone Phailin in 2013 too.

Table 3 Ports, SEZs, and cities in coastal states in India

State	Coastal district	Total area	Total pop. of the state (in millions)	Pop. coastal (in millions)	Notified minor ports	Major ports	Minor port	Proposed ports	SEZ in coastal areas	Cities along the coast	1 m. sea rise affected % of pop.
Gujarat	17	196,024.0	60.38	39.89	49	1	7	18	2	13	1.07
Daman and Diu	2	112.0	0.243	0.242	2	0	2			1	
Maharashtra	7	307,713.0	112.4	28.63	48	2	14	4	4	6	1.75
Goa	2	3072.0	1.45	1.45	5	1	5	4		3	7.25
Karnataka	3	191,791.0	61.13	4.7	10	1	10	5	1	3	0.56
Kerala	9	38,863.0	33.38	27.46	17	1	18	5	7	19	1.56
Tamil Nadu	13	130,058.0	72.14	33.38	20	3	17	17	10	12	2.91
Pondicherry	1	490.0	1.24	1.24	2	0	1	1		2	
Andhra Pradesh	9	275,069.0	84.66	33.6	13	1	14	10	5	8	0.93
Odisha	6	155,707.0	41.94	11.62	14	1	12	9	1	4	1.76
West Bengal	3	88,752.0	91.34	29.28	1	1	5	3	5	6	2.35
Andaman and Nicobar	3	8250.0	0.38	0.38		1	23			0	
Lakshadweep	1	32.7	0.064	0.064		0	10				
	76	1,395,933.7	560.747	211.936	181	13	138	76	77		

Source: <https://censusindia.gov.in/2011census/dchb/DCHB.html>
https://censusindia.gov.in/2011census/population_enumeration.html

Since 1975, Andhra Pradesh has witnessed nearly 60 cyclones which includes Titli in 2018, Fani in 2019, and Amphan in 2020. Nisha in 2008 made cyclonic impact in Cuddalore district of Tamil Nadu and damaged major parts of Sri Lanka. Cyclone Nisha 2008, Phyan 2009, Thane 2011, Nilam 2012, cyclone Vardah 2016, cyclone Ockhi 2017, cyclone Nivar 2020, and cyclone Burevi 2020 have caused devastation in Tamil Nadu.

Tauktae in Arabian Sea is one the strongest cyclone in 2021. Severe cyclone Nisarga made landfall slightly away from Mumbai in 2020. Cyclone Phyan 2009 caused heavy rainfall in Gujarat. From 1999 to 2020, there is a loss of property assets from \$2990 million to \$14,920 million which accounts roughly 2% of the country's GDP. From West Bengal to Tamil Nadu, the districts of eastern coastal region are highly vulnerable for cyclones. Twenty-five districts of the east coast are highly vulnerable to cyclonic storms which include ten districts from Tamil Nadu, seven from Andhra Pradesh, six from Odisha, and two from West Bengal.

A rise of 1 m in sea level would inundate nearly 6000 km² areas in India. The population living in these low-altitude areas is most exposed to natural hazards and disasters. Approximately, 63 million people live in a fear of exposure to these disasters with low resilience, particularly the poor communities. Due to climate change, infrastructure, ports, industries, and agriculture pattern of coastal region will be affected to a greater extent.

From management point of view, there is a need to improve the cyclone warning system, more addition of evacuation shelters, and increase in area of shelterbelt plantation and mangroves. State government must provide concrete and resilient households to the poor. This all can be achieved only when center and concerned states ensure healthy coordination to achieve zero fatality approach and minimize economic losses.

Conclusions

As a result of globalization, the varied and highly productive ecosystems on the coastal zone are under pressure due to increased anthropogenic activity. It is necessary to protect our ecosystems to ensure sustainable development of urban areas. Also, it is crucial to assess the interaction between various industrial and human activities conducted in coastal areas. To protect our environment, ecology, and its endangered species, there is an urgent need to ensure judicious use of resources around coastal zone. The poor are most at risk in cities due to exponential growth of urbanization. These urban poor are compelled to live in slums which emerged in low-lying areas. These low-lying areas are frequently exposed to coastal flooding and waterborne diseases. India must take great care to protect the natural assets and livelihoods of coastal people by making coastal governance transparent and accountable at the district level. There is an absolute need to have coastal policy, urban planning, coordination, capacity building, involvement of the civil society (local community in the decision-making process), assessment of damage, implementation

of CRZ, and information dissemination. Coastal areas as a resource in India are its natural assets, which every citizen has the right to use and protect. There is an urgent need to transform the old pattern of coastal management through artificial intelligence which may result in the socioeconomic development of coastal people.

Abstract

Human civilization today is facing perhaps the worst kind of challenges for its survival, which are emanating from diverse fronts. Some of them are a product of man-made conscious decisions resulting in several ecological disasters. These are having profound consequences on the survival of the human race in the twenty-first century. Those natural and man-made disasters are posing serious threats to human security and are proving to be beyond the control of individual nation-states to mitigate and resolve pertinent issues such as climate change, global warming, and environmental degradation.

Hence, it calls for not only form resolve but also collective action, collaborative efforts, and innovative strategies by the nation-states to pull in their resources and share technology, information, and best practices. Decision-making of late has become a primary objective of every nation struggling with natural disasters

S. Dhal (✉)

e-mail: sangitadhal@kalindi.du.ac.in

taking place at alarming frequency. Hence, it is pertinent to discuss the subject of such great relevance in contemporary times to put in perspective the need for the right kind of strategy at the local front and collective action plan at the global front.

In the post-globalization era, much of the states' responses to challenges on multi-various fronts are articulated through substantial intervention of ICT. This has made the process of governance more efficient and faster in responding to the challenges and effective management of crisis. In brief, the new-age governance, popularly known as e-governance, provides a wide range of technical solutions, which are proving to be a game changer. An attempt has been made to contextualize disaster management in the larger process of e-governance initiatives of the states across the globe to respond to the challenges of climate change and its consequence on human lives.

Disaster management · E-governance · Community participation · New technologies · Communication · Common service centers

A Catalytic Role for ICT-Based Services in Disaster Mitigation

In the contemporary times, both natural and man-made disasters have become a challenge for the mankind. They pose a serious threat to the survival and livelihood of people in different parts of the world that must be adequately addressed through the prevention, preparedness, and mitigation strategies. Countries across the world are facing natural disasters in the form of tsunami, severe cyclones, floods, excessive rainfall, landslide, etc. At the same time, there have been instances of man-made disasters taking place due to excessive economic activities and uncontrolled exploitation of natural resources such as mining and depletion of forest resources. These activities alongside rapid urbanization have led to the decrease of forest covers and encroachment into agricultural lands, thereby creating situations for natural disaster. Under such circumstances, the role of the state to mitigate these challenges becomes critical. However, given that fact, the capacity and preparedness of the state agencies to effectively address these recurring problems have always remained doubtful. Hence, there is a need for looking at such nonconventional security threats from a new perspective of public policy and management. This needs a multidimensional approach involving greater usage of technology. Both information and communication are important parts of the disaster mitigation strategy which can be extensively used through technological platforms to reach out to the targeted areas and population during natural calamities. Timely informing the unsuspecting people and evacuating them to safer places during such natural disasters save precious lives and valuable property. Thus, alongside government agencies, advanced ICT can play a catalytic role in disaster management efforts.

Each disaster has its own characteristic features, and this has to be taken into consideration while designing the most appropriate disaster mitigation strategy. Disaster management requires the active participation of multiple stakeholders which involves networking and coordination by different departments, organization, and agencies on the basis of information, service, support, and institutional framework. From early warning to post-disaster assessment, information can be shared and analyzed for effective management of disasters at different levels using different communication platforms. This can be used to prevent future disasters or at least control the damage intensity. The efficiency of the government is enhanced by increasing the use of ICT tools in administration, so that knowledge is disseminated faster and enables the citizens to make informed choices. This technological intervention in administration has reached a stage, where it needs to be explored as a critical catalyst to disaster management system. This chapter explores the positive intervention of e-governance, a critical enabler for disaster mitigation strategy through information dissemination. New technologies, such as information and communications technologies, have brought about amazing changes and played an important role by using geospatial information technology to disseminate information and increase community participation and community-based disaster preparedness, which is the key to effective disaster management.

Development Disaster Dichotomy

Ever since globalization unleashed forces to embark on rapid economic development, the pace and volume of economic activities all over the world have increased exponentially. In the era of the *Fourth Industrial Revolution*, the advances in digital technologies have empowered many and also have emerged as a pivotal tool to assist policy-makers for the purpose of delivering public goods and services. While advancements in technology have dramatically transformed the narratives on climate change mitigation and disaster management, they also play a key role to forecast weather across different locations and reduce risks and provide quick response during disasters. The Covid-19 pandemic has exposed the challenges and vulnerabilities at the regional, central, and global levels. Therefore, governments need to revisit the administration by restructuring governance and strengthening public institutions to ensure the achievement of sustainable development goals. In this context, it is pertinent to highlight the role of geographic information system, which in its various dimensions has fast-tracked the idea of disaster management by effective amalgamation of geospatial data and socioeconomic information for better decision-making.

The term “disaster” is to be seen in the context of three distinct situations where development and lack of it become precursors to impending disaster.

- First, disasters destroy hard-earned gains of development.
- Second, lack of development makes vulnerable communities more prone to disasters, than the communities which are better off.

- Third and ironically in an opposite direction, development increases the risk of disasters, such as houses and infrastructure without compliance of zoning and building regulations; mining and industries in ecologically fragile zones may destroy the natural buffer to disasters, while fossil fuel-based production and consumption increase the risk of climate-related disasters.

Most developmental activities, especially in high seismic risk areas, can trigger earthquake and landslides. It is necessary to incorporate earthquake-resistant features in the design and construction of all new buildings and structures. Thus, there needs to be a judicious use of natural resources, keeping environmental concerns at top priority so as to avoid disasters. Though the poor countries contribute marginally to the climate crisis, the actual impact on them is more severe and intergenerational. Climate change is also disastrous for the marginalized groups that face food insecurity, mass displacement, and loss of life and property, and the pandemic (Covid-19) has made it more challenging for them. These extreme consequences highlight the need for concrete climate action, especially finance and technology for the Global South by the developed North. It has been observed that the industrialized North has shown little interest to meet the goal of mobilizing hundred billion dollars for climate finance. It has also failed to provide a roadmap for funding as promised during the Glasgow meet, 2021. The developed world must adhere to the principles of climate justice and provide finance and technology to the developing world.

Apart from constructive cooperation, substantive collaboration, and effective coordination between the developed and the under-developed countries, there is also a need to undertake massive technological upgradation and usage of information and communication networks to face the challenge of recurring environmental disasters. For this, the new-age governance system based on the application of ICT tools and digital infrastructure supporting disaster mitigation efforts is considered to be the “game changer.” In other words, e-governance and its various technologically enabled means can prove to be a catalyst.

Knowledge, Innovation, and ICT Tools: Creating Public Awareness

In an event of a disaster, communities are always the first responder. Community participation ensures local ownership, addresses local needs, and promotes volunteerism and mutual aid to minimize and control damage. Community-based disaster preparedness is vital for effective disaster management (www.osdma.org). Imparting education raising awareness among the vulnerable communities, community-based monitoring, timely warning, and effective evacuation strategy are key to disaster mitigation strategy.

For example, Japan has a known history of natural disasters happening at a regular interval, some of which are the direct consequence of climate change. Besides earthquake and tsunami, there are typhoons, floods, landslides, and volcanic eruptions in Japan that has learned to live with natural risks making it a laboratory for resilient societies (Mihoko & Murayama, 2019). Japan Bosai platform: is a group of

firms that develop disaster-related technologies. Concept of resilience is what can be emulated by other countries from Japan (Omachi, The Economist, December 7, 2020).

The challenges of sustainable development and climate change are addressed by adopting green technology for the recovery, recycle, and management of wastes. However, the real issue is to move beyond the binary discussion of environment and development to environmentally sustainable and socially inclusive development mode. India has also initiated a multi-stakeholder partnership, Coalition for Disaster Resilient Infrastructure (CDRI), 2019, that aims to develop strong infrastructure in areas prone to frequent natural disasters; it has also launched an initiative infrastructure for resilient island states for vulnerable island nations as per the recommendations of COP26.

ICT plays an important role in disaster risk management; all stakeholder must be kept in the loop starting from the Ministry at central level with the grassroots developments relating to land use, developmental projects, road networks, communications networks, power plant grids, and water pipelines and must integrate disaster risk reduction practices into the planning process, which is possible by optimum utilization of e-governance applications and techniques.

Another new technique of weather forecasting relates to **Doppler weather radar system (DWRS)**. For a city like Delhi, forecasting of rain and thunderstorms is going to be more accurate with the India Meteorological Department (IMD) installing a third Doppler weather radar (DWR) system that predicts precise warning about rain, thunderstorms, dust storms, and severe weather conditions that can potentially impact flights into and out of Delhi. These orders have been designed and developed indigenously by IMD and the Indian Space Research Organisation (ISRO). Till January 2022, India had 33 operational DWRS. The Doppler installed at Leh is at the highest altitude anywhere across the country, which has proved to be successful in the use of information, response, and recovery phases of disaster (Gandhiok, 2022).

Application of E-Governance in Disaster Management and Disaster Risk Reduction (Pre-, During, and Post-Disaster Periods)

Natural calamities have taken a heavy toll on the lives of the poor and hapless people of the state leading to a situation, where basic human rights violations have taken place on a wide scale. The Sendai Framework for Disaster Risk Reduction and the recent advances in ICT, geographic information system (GIS), dissemination of sensing devices, and creation of networks have led to substantial reduction of losses in lives and livelihood during disaster. It has also led to better accuracy and enhanced the collection of different types of information regarding spatial data for cities, regional diversities, and environment that has provided the technical expertise for social development and urban and rural planning strategies (Choudhary & Vyas, 2020).

The United Nations Economic and Social Commission for Asia and the Pacific (UNESCAP) Report, 2017, emphasizes the use of ICT in all phases of disaster risk management to reduce risks, enhance coping capabilities, and provide quick response through ICT-enabled public administrative system. E-governance offers many opportunities for better information sharing efficiency and better service to citizens. The efficacy of the government is enhanced by increasing the use of ICT tools in administration, so that knowledge is disseminated faster and enables the citizens to make informed choices. UNESCAP promotes digital inclusion through latest ICT trends, cloud computing, and the power of big data that simplify everyday tasks (<http://www.unescap.org>).

- The role of ICTs is also recognized in terms of risk maps, as well as using GIS and ICTs for more accurate measurements.
- Education and awareness generation among communities.
- Establishing community-based monitoring.
- Timely warning.
- Effective evacuation strategy.

Sendai Framework for Disaster Risk Reduction 2015–2030

- Understanding disaster risk
- Strengthening disaster risk governance to manage disaster risk
- Investing in disaster risk reduction for resilience
- Enhancing disaster preparedness for effective response and to “Build Back Better” in recovery, rehabilitation, and reconstruction

The rapid advancements in technology have opened up the possibility where ICTs have the potential to play an indispensable role in all stages of the disaster life cycle. However, they cannot be treated as stand-alone applications or services (Reza, 2010). An ecosystem needs to develop with policies and plans in place that provides a clear roadmap for all institutions, community groups, and governmental and non-governmental organizations. Application of geographic information system (GIS) is useful for identifying the exact location and coordinates in the event of a disaster, so that relief could be dispatched at the earliest (www.unescap.org).

Application of Geographic Information System in Disaster Management

Geographic information system (GIS) refers to specialized databases and systematic integration information through hardware and software for capturing, storing, displaying, updating, manipulating, and analyzing spatial data. GIS system follows a decentralized three-tier structural framework that is an integration of primary components consisting of hardware, software, data, and people for better

preparedness, which is transparently managed. GIS is a powerful tool and involves experts that include cartographers and surveyors who create the maps and survey the land along with the geographical features (Dhunna, 2009). They also include system users who collect the data, upload the data to system, and analyze the results. According to the Environmental Systems Research Institute, 2010 (ESRI), GIS integrates data for capturing, analyzing, and displaying all forms of geographic information that can be shared easily through maps and charts. It keeps information in different layers and generates various combinations pertaining to the requirement of the decision-making. In the recent times, GIS has displayed enormous potential in the management of disasters, effective coordination of geospatial data, and socio-economic information for better decision-making in handling a disaster in a better way through planning and organizing capabilities. Different line departments and staff agencies who are stakeholders in the disaster management process use GIS as a medium to address issues of disaster management.

GIS has been effectively used in the following cases as a decision support tool.

- Identification of location for construction of multipurpose cyclone shelters.
- Grid analysis for setting up the automated weather stations (AWS).
- Preparation of the district- and village-level vulnerability maps.
- Strengthening of embankment and repair of roads.
- Identification and demarcation of weak points in the embankments and area to be affected by flood for preparedness planning.
- Preparing the base map indicating location and operation of boats and deployment of rescue personnel. For instance, GIS was extensively used in Odisha as a part of the Incident Command System and Decision Support System during the air dropping operations in management of floods in 2007 and 2008 and super cyclone “Phailin” in October 2013.

Burrough et al. (2016) highlight the importance of spatial data and the relevance of geographic information system in the modern world for solving a variety of practical problems. The process of GIS revolves around four significant steps:

- Creating data for accuracy
- Managing the data available in geographic and spatial technology
- Analyzing tools
- Display in the form of hard copy or in the web

GIS has been profusely used in map application and remote sensing and inevitable for any planning and space application and has helped to provide quick and able support in efficient disaster management. Furthermore, the digitalization of every village is possible through the application of GIS technology and through the village GIS cell (Google Earth application). Geographic information system along with spatial information technology known as remote sensing has profound implications in the governance and administration of the modern state which requires multifaceted planning and management. GIS enables the creation of a pervasive geospatial

platform, which plays a critical role in several areas like administrative mapping, land use mapping, terrain mapping, social mapping, drainage map and waste management, sewerage management, energy distribution, shortest route analysis, Google Maps services, Global Positioning Systems, and agro-industry location mapping. These services are universal in nature. Today, many local bodies in India are using GIS data for city development planning, urban conservation, documentation of biological diversity, and designing the disaster management programs.

Emerging Technologies and Disaster Risk Management [DRM]

There are various emerging technologies that have the potential to enhance various aspects of the disaster risk management [DRM] functions. Disaster management depends on a multi-sectoral response to work together to identify and implement solution. It refers to a multi-agency function that relies on administrative data and involves networking and coordination by different departments, organizations, and agencies on the basis of information, service, support, and institutional framework. Information dissemination through print and social media platforms is a crucial part of disaster management. In the recent times, GIS has emerged as an effective tool in the management of disasters since geospatial data and socioeconomic information need to be amalgamated for better decision-making in handling a disaster in a better way (www.unescap.org).

The Sundarbans, the world's largest dense mangrove forest cover, was severely hit by two cyclones, *Amphan* in May 2020 and *Yaas* in May 2021, that took a toll on the vegetation and severely damaged the delta region by increasing the salinity levels. The cyclones in every successive year have a profound impact on the natural ecosystem of Sundarbans. It has been found that the natural vegetation and the natural habitat of the wildlife have come under severe stress and irreversible damage. Given below are the various techniques and applications of e-governance strategies adopted in disaster management.

Artificial Intelligence (AI): is considered as a major game changer in diverse sectors that has immense potential to mold India's future. AI refers to the practice of designing computer systems to make prudent decisions based on the real-time data (Dhal, 2022). The most common application of this technology is the field of virtual assistants (machine learning-aided assistance) which is gaining currency in the wide areas of energy conservation, climate change, disaster preparedness, and environment monitoring.

Big Data: relates to the huge volume of data that cannot be processed using traditionally available computers and data processing software and techniques. Big data along with artificial intelligence (AI) can be an effective means for disaster mitigation strategy and effective disaster relief programs. Adopting AI in disaster management strategies has profound consequences for the society in implementing the Sendai Framework for Disaster Risk Reduction 2015–2030 (Kumar & Sud, 2019). It also provides timely information on human behavioral patterns such as

migration, mobility, social network, and so on. This has resulted in the generation of a large amount of data which has to be collected, categorized, and analyzed.

Unmanned Aerial Vehicles: In recent times, the unmanned aerial vehicles (UAV) commonly known as “drones” are used for disaster risk management (DRM) purposes, mainly in the critical phase of response and recovery. Their aerial view imagery and mapping gives an estimate on the extent of the damage and can help identify bodies trapped under debris. In areas of severe damage where transport links have been destroyed, drones provide a way of assessing the gravity of the situation. This is very useful where human personnel can't go because of the risks involved or inaccessible situations.

Community Response Grids (CRGs): CRGs make use of the Internet and mobile communication devices, allowing residents and responders to share information, communicate, and coordinate activities in response to a major disaster and facilitating assistance.

The rationale behind the application of various ICT tools and application of e-governance strategies are based on the assumption that their adoption will make a huge difference for disaster preparedness and disaster mitigation strategies.

Institutional Apparatus for Disaster Management

An in-depth analysis of the structural framework of the disaster management apparatus is characterized by a host of decentralized institutions that address the various changes and challenges through effective strategies and action plans. This also needs to be addressed by strong resolve and effective policy interventions by the government as well as by the introduction of innovative methods and application of ICT tools in the disaster management sector and through the development of adequate warning systems.

India has an extensive multi-tier natural disaster warning system, at both the central and the state levels (refer to Fig. 1). This also provides protection to the vulnerable groups in the society, who are affected the most by disaster and climate change.

The above figure outlines the significance of the different institutional mechanisms of natural disaster warning system operating and working in coordination at both the central and the state levels. Community-based disaster management also contributes to disaster mitigation strategies. The silver lining in this scenario of climate change and disaster preparedness is the resilience of the common man and their participation in the community preparedness programs to sustain itself by resorting to innovative methods and long-term investment in climate-resilient development and in the disaster management continuum. A case in point is the state government of Odisha that is constantly challenged by environmental degradation and recurring natural disasters.

Since 1965, the state has experienced floods for nearly 25 years, droughts for 20 years, and cyclones for 10 years. To help build efficient disaster management strategies, for the first time in India, the state of Odisha has announced a separate

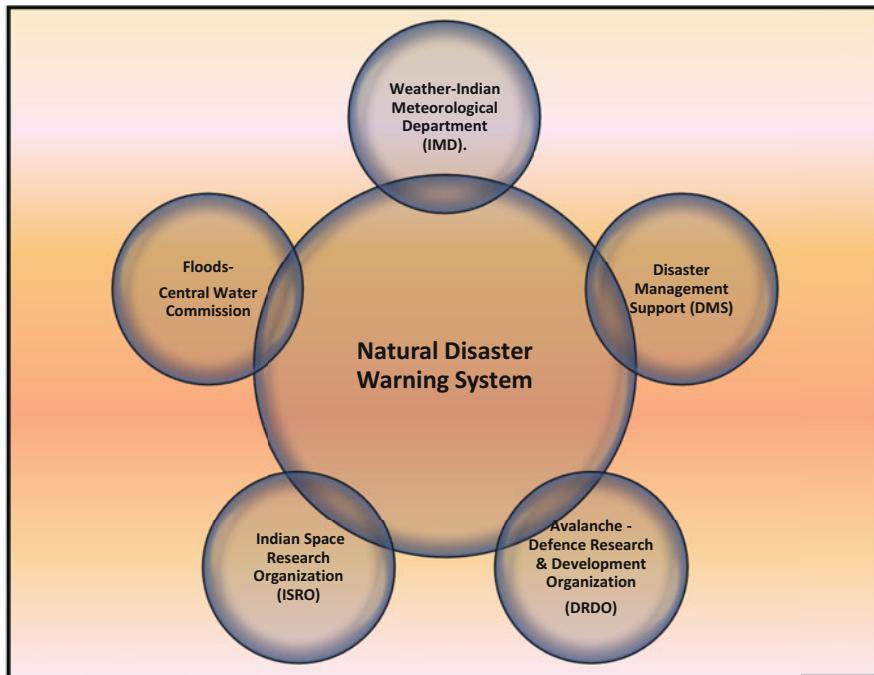

Fig. 1 Multi-tier and natural disaster warning system existing at both the central and the state levels; figure design: author

climate budget (2021) for creating climate resilience infrastructure and closely monitoring its outcome. It has implemented underground power cabling, to address the perennial issue of electric poles getting uprooted during cyclones. Several surge walls were created to prevent tidal wave water from entering the agricultural fields and thereby ruining the crops. When Odisha was hit by Fani super-cyclone in 2019, it impacted the economy in a significant manner (Rs 34,000 crore), and climate-related economic loss has been nearly \$1.5 trillion. So the climate budget introduced in Odisha in 2021 is very significant for building climate resilience infrastructure (<https://poshan.outlookindia.com/story/poshan-news-odisha-leads-way-with-climate-budget/348879>).

Harnessing Technology for Better Disaster Management

The use of various ICT tools artificial intelligence, GIS, drones, satellite imagery, social media, etc. enables the multidimensional understanding of disasters and aids in accessing the devastation and damage for better disaster preparedness. In this context, e-governance as an enabler in administration and governance plays a critical

role in all the three stages of disaster management that include pre-disaster management phase, during disaster management phase, and post-disaster periods.

- In pre-disaster phase: public awareness and sensitization drive toward disaster risk reduction and resilience through media, NGOs, and civil society
- During the disaster: dissemination of authentic information from reliable sources to reduce the panic among public and guide them to take appropriate action during the disasters
- In the post-disaster: sharing information related to rehabilitation and recovery works undertaken by the government

This strategy envisages a paradigm shift with the help of ICT tools from response and relief-centric approach to a proactive and comprehensive strategy toward disaster management taking into account all dimensions of prevention, mitigation, preparedness to rehabilitation, reconstruction, and recovery. It is important to integrate the emerging digital technologies, such as artificial intelligence (AI), social media, space applications, and geospatial information for disaster management.

This section explores how e-governance based on technological applications is adopted as critical disaster mitigation techniques that are used by the different states to address the natural calamities. The following two case studies pertain to the development and excessive economic activities contributing toward environmental degradation in the already fragile ecosystem of Uttarakhand and Kerala.

Case Study 1: Uttarakhand Disaster, June 2013 – Extreme Rains and Haphazard Development

Uttarakhand and adjoining areas received heavy rainfall, which was 375% more than normal monsoon. Nearly 1.5 lakh people were stranded due to heavy rain which resulted in flash floods, cloudburst and landslides. Precautionary steps taken by State Administration were not adequate in foreseeing disaster of this magnitude. None of the agencies like CWC, DMS, GSI, and DRDO except the Indian Meteorological Department [IMD] provided the early warning of the Himalayan Tsunami

Lessons Learned

No warning or advisory was issued by the state government to the residents of the affected areas or vulnerable pilgrims. The Char Dham pilgrimage has become highly commercialized. The tour operators wanted to complete the package ignoring the safety of the vulnerable pilgrims. The district administration was found lacking in organizing coordination meetings during preparatory stage with ITBP, local units of Army. The communication network normally gets disrupted in a disaster. No proper plan for alternative satellite-based communication was available. Though the center was willing to help, the state machinery at grassroots level was not equipped to execute it

(continued)

at field level. The Army somehow succeeded in evacuating the stranded population. Disaster of such a severe magnitude is a wakeup call. It is high time to learn from mistakes and organize the grassroots machineries through effective use of ICT tools.

Another factor of climate emergency has been the massive loss of forest cover due to the Char Dham project in Uttarakhand, which has made the state vulnerable to landslides, slope instability, and downhill creep. Highways have also become perennial problems particularly during the monsoon season. Loss of forests for local people results in the loss of minor forest products and local resources and also increases human and wildlife conflict. (Char Dham Project has increased states vulnerability, Interview with Ravi Chopra, Former Chairman of Panel on Char Dham Project, Sunday Hindustan Times, New Delhi, February 13, 2022).

Case Study 2: Kerala Floods 2018 – Implications of Climate Change

The state of Kerala witnessed heavy floods that were a result of heavy rains from June 1 to August 19, 2018, that was 42% above normal range. With strategic planning, funds were utilized effectively through e-governance techniques. The government handled the crisis situation well due to which the entire world lauded the state of Kerala for its deft handling of the flood of the century. Nearly 7 lakh flood-affected persons have received financial aid, and as many as 687,843 people received financial assistance of Rs10,000. Destroyed dwellings were classified into four groups and efforts were made to rebuild them.

Lessons Learned

Voluntary spirit of the younger generation and the role of technology helped to locate thousands of persons trapped in their homes; it also made the daunting task of distribution of relief materials especially food and water and managing of the relief camps easier. Further, thousands of stranded persons were rescued by the timely intervention of fishing community [super-heroes] who mobilized the rescue mission through their boats.

The experience of the above two natural disasters has flagged an important issue of development strategy, and economic planning is responsible for such unprecedented natural calamities which need to be addressed at a priority basis. This demands a thorough revision and review of the existing approach to economic development in and around such ecologically vulnerable regions where there has been a steady increase in tourist population in recent times. Both Kerala and Kedarnath are major tourist destinations and centers of pilgrimage, respectively, which bring additional pressure on civic infrastructure as well as available resources of the region. These have direct and indirect impact on the physical environment and local ecosystem (Eapen 2014; Kannan 2018).

The following case study 3 is with reference to the second dimension of disaster mitigation where prior planning and preemptive actions have led to a more effective resolution of unanticipated natural calamities.

Case Study 3: Community-Based Flood Early Warning System (CBFEWS) in Malawi

The Sendai Framework for Disaster Risk Reduction indicates that flooding is one of Malawi's most prevalent natural disasters, accounting for about 72% of the natural disasters in the country as recorded in the international database of disasters. A brief analysis of Malawi country profile in the Emergency Events Database (EMDAT) indicates that in the last two decades (2000–2020), Malawi has experienced total 156 hydrological flood (riverine and flash). Most of these flood-related disasters are often accompanied with loss of life, displacement of people, damage to public infrastructure and private homes, and crop and livestock losses, hence reversing the recent economic gains accrued. Many homes get flooded in most years, hence trapped in a poverty-vulnerability cycle limiting their opportunities for growth. It is projected that climate change, vulnerability, and population growth will expose the already vulnerable communities to increased flooding frequency and intensity resulting to enhanced economic and humanitarian disasters that require immediate attention.

The current flood early warning systems in Malawi are insufficient to provide the most vulnerable communities with timely and actionable flood warning information that can help them make decisions that reduce disaster risks and improve their livelihoods. Investing in community-based flood protection measures and early warning systems provision are being embraced to reduce the risk while improving community resilience to disasters. The priority for the Government of Malawi is to enhance adaptation and mitigation measures as reflected in the policy framework (2015) and national guidelines on early warning systems (2018) which lists a number of initiatives for flood disaster risk reduction. A total of 21 community-based flood early warning systems (CBFEWS) were installed and tested for the flooding rivers within the 8 selected districts (Karonga, Rumphi, Nkhata Bay, Nkhotakota, Salima, Dedza, Zomba, and Phalombe). The installed and tested CBFEWS comprises three units, namely, the Data Acquisition (DA) unit, the Data Upload (DU) unit, and the Alarm Unit (AU). The DA unit was installed depending upon the site feasibility: In the presence of bridge, the DA unit was anchored on the pillar of the bridge, whereas in the absence of bridge, the DA unit was assembled on a well-stable concreted galvanized metal structure. The water level of the river is periodically monitored through the contactless ultrasonic-based technology which transmits the measurements wirelessly to the DU unit. The DU unit placed at the caretaker's house within the communication range

(continued)

Fig. 2 Field demonstration of the CBFIEWS (DA) assembly and operations through community engagement and sensitization

Fig. 3 Leman Ngwena of DWR following the CBFIEWS installation and testing using the video provided

then processes the water level to generate localized messages and warnings and uploads measurements to a remote server through a cellular data connection. After processing the measurements received, the server then proceeds to display the data in a time-wise chart. The AU has been installed in the vulnerable downstream communities along the same rivers where DA and DU are installed. The AU sounds a loud siren after receiving the correct SMS that enables the flood early warning dissemination. The relay of the signal is done through an available cellular network compatible with 2G/3G/4G signals that are adequate for data transmission.

Despite field challenges, the CBFIEWS equipment, supply, installation, and testing were considered successful. A total number of 21 CBFIEWS stations were installed and tested to address the issue of perennial flooding and also through continued community engagement and awareness creation programs (refer to Figs. 2 and 3).

Source: Report on Establishment of Community Based Flood Early Warning Systems (CBFIEWS) in selected districts in Malawi, Department of Disaster Management Affairs, Malawi and UNDP, November 2021.

Disaster and Community Participation

Considering the recurring phenomenon of natural disasters taking place with unprecedented alert kitty in contemporary times, it is imperative for the government to revisit its strategy to mitigate these challenges. It needs a fresh look at disaster management and community participation in the efforts of the government. The impact of these natural disasters is sometimes so high that their efforts of the government are found wanting and people are left to fend for themselves. Hence, a collective mechanism involving the community and the civil society needs to be evolved for a well-coordinated response to disasters and natural calamities. The role of women self-help groups in this context is considered to be very critical for the very reason that such civil society agencies are considered to be the front line of defense as they are very familiar with the locality and share informal rapport with the local population.

During any disaster, community participation and technology play a critical role and help to prevent and minimize damage. Timely information of natural calamities and disaster management along with accurate weather forecast helps the local population especially those residing near the coastal regions, who generally remain at the mercy of the nature. Realizing the utility of the grassroots agencies for last-mile delivery of services like the common service centers (CSCs) for social change, the National Disaster Management Authority (NDMA) has involved the CSCs for spreading public awareness and information on the effective management of natural and man-made disasters that promotes better citizen-government interface.

Another game changer initiative relates to the significant role played by the women self-help groups in rural India for achieving women's empowerment and contributing to social capital by guaranteeing sustainable livelihood opportunities. It has been observed that women try to overcome the social prejudices against them through group solidarity and active participation in the public domain of socioeconomic spaces. A newfound awareness and the confidence among the women members are instilled by their indigenous skills and training vis-à-vis their men folk (Social Capital: A Shared Destiny, Second Administrative Reforms Commission, 9th Report, December, 2008).

It has been often observed by the local administrative authorities and agencies that WSHGs are effective community-based disaster management unit. They are the first line of volunteers who can aid the government machinery as service providers to reach out to the target population. The district administration in the various states of India has encouraged the WSHGs to enhance capacity building for helping the government machinery and the local administration in disseminating information and delivering services during disaster (Mohanty et al., 2013).

Conclusion

History of the evolution of mankind shows how human species have always converted every challenge into great opportunity and have negotiated with them through innovative ideas and meticulous planning. While confronted with ecological

crises of the twenty-first century, a multipronged approach is being adopted by every nation to mitigate those challenges. Contemporary environmental challenges are addressed through creating robust infrastructure, aided by emerging technologies and developing effective disaster mitigation strategies. However, for long term solutions of these problems, there is a need to adopt sustainable economic development and a coordinated action plan for the ‘global south’, who cannot afford the cost of environmental protection. At a time when the world is facing major environmental catastrophes, manifested in different forms, such as climate change, recurring tsunami, and global warming, there is an urgent need for collective and coordinated global action. In order to mitigate such challenges and save humanity from imminent danger of possible extinction, policy planners must come up with innovative solutions. Such endeavors must focus on the vulnerability and adaptation to climate change both at the global as well as at regional levels.

In this context, few recent endeavors are worthy of commendation. The quadrilateral initiative (QUAD) among four major democracies, the USA, Australia, Japan, and India, in the Indo-Pacific region is today emerging as a robust platform for achieving multi-various strategic objectives including climate action plan. According to Antony Blinken, US Secretary of State, “QUAD is becoming a powerful mechanism for delivering, helping to vaccinate a big part of the world, strengthening maritime security to push back against coercion in the Indo-Pacific region, working on emerging technologies” (quoted in *Hindustan Times*, February 10, 2022). Though QUAD today is seen as a strategic alliance against growing Chinese expansionism, its original mandate is reflected in the agenda of the organization at its inception in 2007 in the aftermath of the deadly tsunami that struck this region in 2004. There are other noteworthy initiatives like the international solar alliance pioneered by India under **One Sun One World One Grid (OSOWOG)** that is aimed at addressing the issue of climate change and environmental degradation through alternative renewal energy.

Another important component of disaster mitigation is “capacity building” of not only disaster management authority but also the vulnerable people who are at the receiving end. States must build their capacity to withstand, adapt, and recover from natural disasters so that their people can continue to lead the kind of lives that they value. The Sendai Framework for Disaster Risk Reduction 2015–2030 highlights the importance of strengthening the technical, financial, and administrative capability and preparedness of institutions, governments, and communities to successfully handle disasters at different levels. These measures address the issues of sustainable development and climate change as well. However, the challenge is to move beyond the dichotomy of environment and development to environmentally sustainable and socially inclusive development model through the application of knowledge, innovation, and ICT. To reduce and prevent the drastic impact of climate change on vulnerable citizens across the state, there needs to be nationwide concerted efforts to

understand the crisis and devise state-specific plans. Targeted interventions and strengthening the digital reach are the different ways in which gaps can be bridged.

Abstract

Disaster risk reduction, mitigation, and resilience issues as of today form the core of any states' policy intervention. A huge gap exists between developed and developing world in general for preparedness and handling of nuclear disaster capabilities, India being the particular case. Fukushima nuclear disaster and capture of Zaporizhzhia and Chernobyl nuclear power plants in Ukraine by Russian forces have raised alarms regarding nuclear security and safety issues. A global demand for better approaches and methods for building resilience against disasters in general and nuclear disaster in particular is established worldwide, including India. India in recent years performed unsatisfactorily in handling of COVID-19 pandemic in terms of safety, resources, health infrastructure, specialized medicines, vaccines, and medical personnel; therefore, massive policy interventions of the Indian state for building resilience against nuclear disaster are required.

The study inquires India's imperatives for dependence on nuclear energy with probable dangers of a nuclear disaster. It maps domestic legislations, international obligations, preparations, and necessary structures for building resilience against nuclear disaster. It explores various strategies, necessary groundworks, and lessons learned in aftermath of past nuclear disasters, for mitigating disaster risks and building resilience against future nuclear disaster. The methodology used for the study is largely content analysis of literature available in public domain. There are three sections in this study: the **first** section discusses probable causes for rising threats of nuclear disaster; the **second** section highlights various levels of nuclear disaster mitigation planning; and the **last** section presents conclusion by identifying contemporary challenges and emerging debates regarding fresh policy interventions in India for making it a nuclear disaster-resilient society.

Keywords

Nuclear disaster · Nuclear energy · Nuclear war · NDMA · NDRF · Disaster resilience

Introduction

The losses attributed to disasters on a worldwide basis are reflected in the UN report titled "Disasters and Disaster Risk as Development Challenge (UNISDR, WMO, 2012)" that says in the year 2000 onward, more than 1.1 million deaths occurred and 2.7 billion people got affected because of disasters. An amount of \$1.3 trillion was lost during that period. India has a history of having been struck with mega man-made Bhopal gas disaster in 1984 in which around half a million people suffered because of leakage of poisonous chemical fumes/gas from Union Carbide chemical plant. It is disappointing to note that the issue of complete rehabilitation and payment of compensation to all Bhopal gas sufferers is still incomplete even to

today. The final settlement is still languishing between different government agencies and Indian courts in 2022. India's disaster handling vulnerability got exposed recently, when it struggled hard in handling of COVID-19 pandemic disaster. It is because of India's poor records of handling of any disaster in general and nuclear disaster in particular that a serious concern gets raised about its handling capacities of a probable nuclear disaster. This chapter helps us in problem identification, establishment role, policy analysis, and mitigation planning.

Out of several studies on disaster losses in India, the study done by the Integrated Research and Action for Development (IRADE) categorically points out that most of Indian cities lack disaster resilience (https://irade.org/ISET_Report.pdf). The Russian attack on Ukraine in March 2022 and subsequent capture of Zaporizhzhia and Chernobyl nuclear power plants by Russian forces and their constant threats to make use of nuclear weapons against NATO countries to stop them from supporting Ukraine have raised fresh alarms over nuclear safety issues all over the world. The hostile policies of India's two nuclear neighbors Pakistan and China are known for creating additional military security and nuclear safety burdens on India. The precipitation of a crisis on India-China borders in May 2020 at Galwan in Ladakh has triggered a fresh debate on nuclear safety issues in India. It is sheer coincidence that world over, a fresh debate has started demanding use of better approaches and methods for building resilience against disasters in general and nuclear disaster in particular.

In light of India's Chief Economic Adviser V. Anantha Nageswaran's observation, India would become a \$5 trillion economy by 2026–2027 (The Hindu, 24 June 2022); hence, it is important for country's planners to focus on the mainstreaming of nuclear disaster risk reduction plan in their all disaster plans at national, state, district, and local governments level. India's Nuclear Disaster Management Guideline-Nuclear, Radiological and Nuclear Emergencies (NDMG-NRE) (For details of NRE, please visit <https://nidm.gov.in/PDF/pubs/NDMA/6.pdf>) provides a roadmap for handling of nuclear disasters in the country (www.ndmg-nre). It needs to prepare itself so as to avoid colossal economic loss on account of disasters of any nature.

Till now the disaster mitigation plan is confined to government agencies like Nuclear Disaster Management Authority (NDMA), Defence Research and Development Organisation (DRDO), and armed forces of the country. Citizens have remote chances of having any official training and awareness about nature and risks arising out of nuclear or radiological disaster, and there is always a scope for enhancing their participation in nuclear safety debates in the country.

This study highlights India's imperatives for dependence on nuclear energy with probable dangers of a nuclear disaster. It maps domestic legislations, international obligations, preparations, and necessary structures for building resilience against nuclear disaster. It explores various strategies, necessary groundworks, lessons learned in the aftermath of Fukushima disaster, COVID-19 pandemic, and recent Russia-Ukraine war in March 2022 for mitigating disaster risks and building resilience against nuclear disaster. It also highlights upon a policy of safety, preparedness of local communities, training methods, etc., for realizing the goals of transition from

preparedness and risk mitigation to resilience against nuclear disaster. The methodology used is content analysis only. There are three sections in this study: the **first** section discusses probable causes for rising threats of nuclear disaster; the **second** section highlights various levels of nuclear disaster mitigation planning; and the **last** section presents conclusion by identifying contemporary challenges and emerging debates regarding fresh policy interventions in India for making the country a nuclear disaster-resilient society. The chapter doesn't discuss all types of disaster under CBRN category and covers nuclear issue only.

Nuclear Disaster Risks: Causes and Concerns

Accidents at Nuclear Power Plants

Since the signing of India-US nuclear agreement in 2008, India in light of its energy security goals has embarked upon a huge nuclear power generation program, besides generation through coal, gas, hydro, wind, or other renewable sources of energy, which has increased the probability of nuclear disaster becoming a reality on patterns of Fukushima nuclear disaster of 2011. India is of the view that nuclear energy does not affect climate change, because it is a cheap source of clean energy and its costs can be reduced to the level of energy through coal over a period of time. By 2032, India is likely to generate 60,000 MWs of electricity through nuclear route. (NPCIL, 2008). As of year 2022, it has nuclear power plants at seven places with 22 nuclear reactors that are functional, and another 60 new nuclear reactors are likely to be set up by the year 2032 because of India's nuclear agreements with countries like the USA, Canada, the UK, France, Japan, South Korea, and Russia. The probable risk of nuclear accidents at any of the existing 22 Indian nuclear reactors or additional 60 reactors likely to be set up can't be ruled out.

Post 9/11 period, concerns regarding chemical, biological, radiological, and nuclear (CBRN) disasters have increased substantially. The likely use of weapons of mass destructions like biological, chemical, or radiological (dirty bombs) by terrorist organizations on a worldwide basis has risen considerably. Use of nerve gas or anthrax by non-state actors has happened in different parts of the world. Several laboratories are functional where researches on pathogens have been taking place and issues of safety and security concerns have always been there. The case of alleged leakage of coronavirus (bioweapon) from Wuhan lab in early 2020 is still a mystery. However, the present chapter primarily discusses about nuclear issue only. As discussed in preceding paragraphs, India's nuclear power generation has witnessed considerable pace in construction and commissioning of around 60 nuclear reactors by 2032 of an average 1000 megawatts each, thereby leading to several fold increase in its civilian and military nuclear programs.

India's nuclear disaster plan under National Disaster Management Act (NDMA), 2005, has detailed provisions regarding disaster handling legislative framework consistent with domestic and international norms and practices, highlighting various structures needed for undertaking disaster-related rehabilitation and reconstruction

measures, etc. As India's nuclear program is regulated by the Department of Atomic Energy (DAE) under Govt. of India, the DAE has the primary responsibility of managing the accidents at nuclear power plants till date. However, in case of India's National Disaster Management Authority (NDMA), 2005, one is still uncertain whether the NDMA has developed postdisaster response strategy capabilities only or it has also succeeded in putting in place preventive strategies effectively. However, one may experience a complete absence of any CBRN intelligence mechanism functioning on a continuous basis on a countrywide basis. Experts have divided opinions over nuclear energy being the example of clean energy and are of the view that despite public concerns over least possibility of onsite accidents, waste disposal, and uncertainties over economics, fuel switching over to nuclear power remains the largest, proven, carbon-free generation option (Petras & Morley, 1988, pp. 151–153). All such disaster risks remain valid in case of densely populated countries of South Asia including India, Pakistan, and China. The section below discusses various causes that might lead to nuclear disaster.

Use of Nuclear Weapons in a War and Nuclear Proliferation Concerns in South Asia

The study is of view that the greater the dependence of India on nuclear energy, the greater would be the risk of accidental nuclear disaster at nuclear power plants. Even risk of climate change-induced tsunamis leading to disaster at nuclear plants based in coastal areas can't be ruled out. The threat of a probable nuclear disaster in South Asia remains on a higher side because of the presence of three nuclear powers, India-China-Pakistan shares geographical boundaries with each other, that too with a historical burden of having fought several wars with each other. Given that vast populations live close to India-Pakistan and India-China borders, chances of conventional wars turning into a nuclear war can't be ruled out. Any nuclear war would lead to official use of nuclear bomb against each other, or similar use of dirty bombs by non-state actors remains very high. Any exchange of nuclear weapons during a war in South Asian subcontinent would be catastrophic, and it would result in disaster of unmanageable scale.

Another issue that deserves mentioning here is regarding the border skirmishes between India and China in Galwan Valley in East-Ladakh near Line of Actual Control (LAC) in June 2020 that has aggravated probable nuclear crisis debate in South Asia. The India-China borders have emerged as a new battle ground for stationing of strategic arms close to their borders. The beginning of a war between Russia and Ukraine in February–March 2022 has further aggravated the nuclear crisis situation at international level.

The annual reports of different years of nuclear watchdogs such as SIPRI (<https://www.sipri.org/>) or IAEA (<https://www.iaea.org/>) suggest that South Asia has always been prone to acts of nuclear proliferation. Such subversive activities increase the threat of use of nuclear material by non-state actors against army or security personnel for revenge purpose. This type of threat looms large against India, that

is, the threat of use of crude nuclear devices against members of armed forces deployed in UT of Jammu and Kashmir during combing or counterinsurgency operations. The presence of extra powers like the USA and Russia in the region further aggravates the situation. The security situation stands deteriorated after the exit of US forces from Afghanistan in August 2021, as later has a poor record of having failed in stopping the use of their soil by internationally banned terrorist organizations.

It is pertinent to mention that the UN got a Treaty on the Prohibition of Nuclear Weapons (<https://www.un.org/nuclear>tpnw>) (TPNW) readied in 2017, and it came into force on January 20, 2021, so as to completely ban any development of weapon or to test any weapon, or to acquire, possess, or stockpile, use, or threaten to use nuclear weapons on part of signatory countries. However, there were no major outcomes during the tenth NPT Review Conference (<https://www.media.un.org/en/asset>) recently held at the United Nations, New York, from August 1 to 26, 2022. Countries continue to have differences over achieving goals of complete global nuclear disarmament. India also continues to pursue a policy matrix of reliance on nuclear technology for its security and development discourse. On the whole, it can be argued that in case of an outbreak of a nuclear war, management of nuclear disaster would be a highly difficult proposition in case of affected Indian cities. The author has written in detail elsewhere about possible causes of eruption/occurrence of a nuclear disaster in India (Kumar, 2019).

Nuclear Disaster Risk Reduction and Resilience Building Measures

India's Nuclear Disaster Management Planning

The International Atomic Energy Agency (IAEA) emphasizes on nuclear safety as well as nuclear security. The idea is to help countries in prevention of accidents at nuclear sites, thereby saving the lives of workers working there. However, nuclear security aspect helps countries in building capacities to prevent stealing of technologies illegally. Any nuclear disaster plan involves three crucial stages: *prevention, monitoring, and action*. As on date, science and technology enables managers at nuclear power plants to make use of dependable, highly precise, and accurate security and safety gadgets to prevent or narrow down the impacts of a nuclear disaster. In the Indian nuclear energy area, Integrated Command Control and Response (ICCR) exercise centers around testing order and control capabilities, reaction systems, and communication infrastructure. India's Department of Atomic Energy and the Atomic Energy Regulatory Board (AERB)/Bhabha Atomic Research Centre have 24 × 7 crisis control rooms for monitoring of radioactivity round the clock and have necessary mandate to tackle accidents occurring in and around nuclear establishments. Since 2005, India's National Disaster Management Authority (NDMA) has its own legislative framework, discussed in subsequent paragraphs, that organizes and carries out its tasks with necessary agencies at national as well as regional levels in case if any nuclear disaster or accident were to occur. In recent

years, Union Government has been going ahead with construction plans to set up around nine nuclear power plants or set up additional nuclear reactors at existing nuclear power plant sites by 2024, at places such as in Gorakhpur (Haryana), Kovada (Andhra Pradesh), Chutka (Madhya Pradesh), Kaiga (Karnataka), Kalpakkam and Kudankulam (Tamil Nadu), Haripur (West Bengal), and Chhaya-Mithi (Gujarat). There has been a rise of around 150% nuclear power plants (NPPs) along the Indian coastline, thereby increasing the threat of nuclear disaster. The reasons of nuclear power plants coming up in coastal areas and related challenges are analyzed in the last section of the study.

Setting Up of a National Disaster Management Authority (NDMA) in 2005 and National Disaster Management Plan (NDMP) in 2016: A Paradigm Shift in Disaster Management

With the objective of moving higher from relief-centric approach to risk mitigation approach, a statutory body known as the “National Disaster Management Authority of India” (NDMA) (<https://ndma.gov.in/about-us/introduction>) came into existence in 2005. As per statutory requirements, corresponding bodies like State Disaster Management Authority (SDMA) and District Disaster Management Authority (DDMA) were also set up in most of the Indian states and union territories (UTs). India had achieved immense success in direction of covering the entire country under the NDMA Act of 2005 for effective handling of COVID-19 pandemic which led to completing the process of setting up of State Disaster Management Departments/State Disaster Management Authorities (SDMAs) in all Indian states and union territories (UTs) (<https://ndma.gov.in/Governance/SDMA>) (www.ndma.gov.in).

Taking forward the disaster preparedness discourse, the Indian Government also prepared a National Disaster Management Plan (NDMP) in 2016 (www.ndmp.gov.in). This NDMP (2016) (For details of NDMP (2016), please visit <https://www.mha.gov.in/sites/default/files/National%20Disaster%20Management%20Plan%20May%202016.pdf>) was prepared in backdrop of three international developments: Sendai Framework for Disaster Risk Reduction (March 2015) (<https://unece.org/sendaiframework#:~:text=The%20Sendai%20Framework%20on%20Disaster,of%20persons%2C%20businesses%2C%20communities%20and>), Sustainable Development Goals (SDGs) (December 2015–2030) (<https://www.un.org/sustainabledevelopment/sustainable-development-goals/>), and Paris Agreement on Climate Change (December 2015) (<https://unfccc.int/process-and-meetings/the-paris-agreement/the-paris-agreement>). This NDMP (2016) enabled India to incorporate global experiences into National Disaster Management Plans for better handling of disasters in the future. The COVID-19 pandemic in 2020–2021 provided the Indian Government an opportunity for operationalizing the NDMA Act of 2005 throughout the country after imposition of lockdown for controlling the menace COVID-19 pandemic in March 2020. In one go, the entire country was brought under the ambit of Union Government administered NDMA (2005). Never ever on any early occasion, NDMA

(2005) was implemented throughout length and breadth of the country. One may debate whether the country and its people were ever prepared to undergo the harshest imposition of lockdown provisions leading to all kinds of hardships including crippling of the entire economy and prolonged lockdown leading to serious breakdown in production and approximately 40 million job losses (ILO Report, 2020). The author has restrictions not to discuss other details here.

Management of Nuclear Disasters in India and Building Resilience Against Nuclear Disaster

India's Nuclear Disaster Management Guideline-Nuclear, Radiological and Nuclear Emergencies (NDMG-NRE) (For details of NRE, please visit <https://nidm.gov.in/PDF/pubs/NDMA/6.pdf>.) provides a detailed roadmap for handling of nuclear disasters in the country (www.ndmg-nre). The NDMG-NRE document has ten chapters, with a lengthy preface, and 134 pages covering all technical and operational aspects of nuclear disaster. It defines "nuclear disaster" as that dimension of emergency situation leading to mass casualties and destruction of large areas and property; unlike a nuclear emergency, the impact of a nuclear disaster is beyond the coping capability of local authorities, and such a scenario calls for handling at the national level, with assistance from international agencies, if required (NDMG-NRE, Feb 2009, p. xxiv).

However, in light of ongoing recent Russia-Ukraine war since February–March 2022, India still needs to work seriously on many lines and adopt new measures for mitigating any type of disaster risk in the country.

The **NDMG-NRE** (ibid) document discusses actions to be taken by the administration in the aftermath of commencement of a nuclear disaster. It highlights elements of rescue, medical care, transportation, evacuation, providing food and shelter, etc. It elaborates on various decision-making structures and SOPs. Soon after the commencement of any nuclear disaster, the disaster management authority shall pass on to the National Crisis Management Committee (NCMC) assisted by the National Executive Committee (NEC), Department of Atomic Energy (DAE), Ministry of Home Affairs (MHA), and National Technical Research Organisation (NTRO) for handling of nuclear disaster emergencies. As nuclear disaster involves spread of radioactivity, it demands presence of specially trained National Disaster Response Force (NDRF), fire service personnel, civil defense, medical supplies, transport, civil supplies, civil engineering departments, etc., for handling of radiation emergency fully equipped with specialized dresses and equipment (NDMG-NRE, 2009, p. xxvii).

It seems that the NDMG-NRE document overemphasizes on involvement of defense department officials in case of nuclear emergencies under the impression that nuclear issues involve maintaining of complete secrecy besides the impression that defense establishments are likely to be targeted during a war. However, if disaster were to occur on any nuclear plant, there is a possibility that civil administration will lack coordination with defense establishment, thereby leading to disaster mishandling. The experience so far suggests minimum connects existing

between civil administration and ordinary citizens of the country as far as awareness about handling of nuclear disaster is concerned. A critical look at situation prevailing during COVID-19 pandemic lockdown imposition in March 2020 wasn't very satisfactory. A country of India's territory size and population still needs to focus a lot on strategies for having better coordination between federal-, local-, and state-level government agencies. They also need to work on developing better use of communication technologies during disaster situations. It was observed during COVID-19 pandemic that Prime Minister Narendra Modi often addressed the Chief Ministers of states and UTs through online Google Meet only. One needs to remember that nuclear disaster situation is expected to be very different from pandemic lockdown situation because of the ill effects of radioactivity on human body and evacuation plans. The situation would be completely unknown in case of dropping of a nuclear bomb.

Role of Atomic Energy Regulatory Board (AERB), Govt. of India

The role of AERB is important for ensuring stringent physical safety of nuclear installations and areas of waste disposal. According to the AERB safety guidelines of December 2009, the responsibility of safety and security of plant site lies with the operator of the plant itself, that is, the government itself, as nuclear power plants in India are owned only by the Government of India. However, the Central Industrial Security Force (CISF) is given the responsibility to take care of security of entire installation and also remain ready to handle disaster scenario in case of emergencies.

Disaster Management Reforms Post-Fukushima and COVID-19 Pandemic

As scholars debated the need for extra attention on nuclear safety in India, the Department of Atomic Energy got safety audits of all nuclear plants carried out in the country. It reviewed functioning of public health systems, availability of medicines, and training of extra personnel, focus on worker's skill development process, and paid extra attention to weather forecasts and earthquake issues. Despite all extra efforts and lessons learned post-Fukushima and during COVID-19 pandemic, it could be said that the operationalization of **NDMG-NRE (2009)** guidelines and **NDMP (2016)** would remain on paper only if proper evacuation plans in a densely populated country like India are not worked out and practiced in advance. In the aftermath of COVID-19 pandemic, there is a realization that spreading of disaster risk reduction and mitigation awareness and community participation about of handling of any disasters has to be undertaken on a priority basis. The manner in which people had been visiting different websites and e-resources for updating themselves about COVID-19 protocols and safety issues, similar awareness, and activism is needed for training and skill enhancement for nuclear disaster handling too. Hence, more transparency and sharing of information and greater connect

between officials of nuclear establishment and ordinary citizens are the need of hour. It is suggested that nuclear energy establishments in India should give more way to exchange of dialogues among different stakeholders comprising resident welfare associations, youth of the country, party leaders, medical scientists, sociologists, environmentalists, economists, and health and nuclear scientists so that nuclear safety issues are discussed and debated on a more regular basis.

Role of DRDO in Handling of Nuclear Disaster

India has another federal government agency, Defence Research and Development Organisation (DRDO), that is engaged continuously in providing training to government personnel and dissemination of necessary information to Union Government officials besides state government officials and their police and civil defense department personnel, who are expected to be involved as frontline warriors in any post-nuclear disaster operations. As on date, the role of DRDO has been commendable in training of medical personnel and several contingents of National Disaster Response Force (NDRF) for handling of radioactivity scenario and use of specialized protective equipment and gears for handling of contaminated goods and stopping the spread of contamination and taking care of evacuees in any of the evacuation plans. It must be said that DRDO till date has saved a huge amount of foreign exchange for the country by manufacturing several nuclear disaster equipment and devices indigenously. The role of DRDO was highly appreciated when India emerged as one of the leading suppliers of face masks and other PPT kits at global level during COVID-19 pandemic. However, functioning of DRDO gets criticized as it is part of a defense security establishment only and remains covered by secrecy and confidentiality clauses of the country, thereby marring the possibility of greater coordination with civil administration of the country.

National Disaster Management Authority (NDMA) and International Obligations

For avoiding nuclear disasters and implementing safety regulations, India is party to the Convention on Nuclear Safety (CNS) (1994) which has provisions to govern safety of nuclear installations (Arun Shull, 2008, pp. 5–6). India also signed IAEA supervised ISSA and brought all civilian nuclear reactors under the IAEA safeguards. In January 2003, the Union Government set up the Nuclear Command Authority (NCA) to manage its nuclear and missile arsenals and prevent its misuse. The complex system of control may be seen as a barrier against accidental or unauthorized use (www.nca.gov.in and Hans Born). In order to prevent proliferation of nuclear technology, the Government of India also got Nuclear Non-Proliferation Law enacted in 2007.

In light of increasing acts of terrorism and proliferation concerns in recent years, almost all cargo entry points in India – be it air, water, or land – are installed with

radiation detection equipment. In order to augment the security of strategic installations, radiological mock drill is being conducted with greater frequency (NDRF Training data, 2017).

As on date, a federal agency, i.e., NDMA, has been conducting series of training program on CBRN emergency handling to security personnel deployed on country's airports and ports, besides conduct of mock drills at important international airports of the country (Public Information Bureau, 2018). Several other exercises were conducted involving state government agencies like SDMA and DDMA. Despite such training programs which are small in number and largely confined to bigger metro cities of the country, it can be said that gaps continue to remain on ground level, and a good number of additional steps need to be taken for sensitization and providing training to NDRF and SDRF officials to deal with acts of nuclear terrorism effectively. The COVID-19 pandemic proved that if the government of today expresses its political will, then achieving difficult goals become easier as it enabled disaster agencies for putting into place standard operating procedures (SOPs) so as to have better coordination between federal and state government officials during lockdown period.

National Disaster Response Force (NDRF) (<http://www.ndrf.gov.in/sites/default/files/13683%20-encl.pdf>) for Handling of Nuclear Disasters

The NDMA (2005) Act lays down constitution of National Disaster Response Force (NDRF) for the purpose of specialized response to natural and man-made disasters. In 2006, NDRF was constituted with eight battalions for which men were drawn from para-military forces. Now NDRF has a total of 15 battalions and 22 regional response centers (RRCs) (http://www.ndrf.gov.in/sites/default/files/NDRF%20Brochure_0.pdf). Every battalion has 18 teams with 45 personnel comprised of medical personnel besides response forces. It is important to mention here that in light of increasing debates regarding CBRN issues in the country, NDRF battalion is trained in handling of CBRN disasters. However, a serious question can be raised here, i.e., can a country with a population of approximately 1.4 billion people be ensured complete safety with the presence of mere 12 battalions of NDRF (each having 1149 personnel) on a countrywide basis? It is in direction of increasing pressure of UN bodies and international obligations arising out of Sustainable Development Goals (SDGs) (2030) that the Indian Government has forced its 28 state governments to create State Disaster Response Force (SDRF) on patterns of NDRF out of their existing police forces for meeting disaster challenges and achieving the goals of building resilience for disasters in India. The final section of the chapter discusses some policy measures undertaken in recent timings toward the idea of implementing goals of building disaster-resilient cities in the country.

Contemporary Challenges before Indian Administration and Emerging Debates in Disaster Mitigation Plans

Inadequate Medical Personnel for Treatment of Radioactivity-Exposed Patients during Disaster

It is imperative for civilian administration at country level in general and in all district headquarters, including Punjab state which is a border state and shares boundary with nuclear Pakistan, for ensuring a large pool of specialized medical personnel trained for handling of post-nuclear disaster situations. It is unfortunate to mention here that preparations for handling of any nuclear disaster at district administration level in the state of Punjab is negligible as the author has done empirical studies for ascertaining that there is a complete absence of participation of local residents of the city in any disaster-related preparedness. It is believed that there is a significant presence of federal members of armed forces at Amritsar city which is close to nuclear Pakistan, and these defense personnel will be sufficient to attend disaster emergencies as they are expected to possess necessary skills for handling of nuclear disaster. It is also experienced that rarely any public or private hospitals have specialist doctors for treating people exposed to severe radioactivity. The increased role of DRDO is needed for imparting of training to personnel belonging to state government cadre as it is known to train mainly members of armed forces only. It is only in recent period that one can come across certain cities having presence of super-speciality hospitals which have started employing medical persons trained in treating radiological-affected patients within their premises. Barring few cases, the scenario remains very scary as it has allegedly been found that most of the medical colleges of the country, including Punjab state, do not train their MBBS students for treatment of radioactivity-exposed patients. It is in recent months that federal government-run hospitals have been set up in Punjab at Bhatinda and Mohali for treatment of cancer patients using nuclear technology at their premises, thereby increasing the availability of medical personnel trained in treating radioactive-exposed persons. There is a dire need for adequate specialized radiologist doctors employed by state governments who can treat patients exposed to radioactivity. They have to have specialized kind of training for taking protective and defensive measures in case of nuclear disaster situation. The COVID-19 pandemic did expose severe weaknesses existing in India's health infrastructure.

Challenges of Climate Change in Coastal Areas and Rise in Protests and Resistance Movements

As discussed earlier, India in recent years has seen 150% jump in construction of nuclear power plants in coastal areas of the country, thereby exposing coastal belt of the country to future nuclear disaster, besides constant threats of tsunamis and

dangerous storms so far. The reason for sudden jump in their number in brief is that nuclear power plants (NPPs) use a lot of water for heating purpose and steam generation so as to generate enough thrust through steam turbines and then producing of electricity through generators and their onward transmissions through different grids. It is easy to cool hot water after tapping of steam and release it safely into mainstream reservoir or recycle it again if needed. It is also considered that coastal areas remain prone to tides and storms; hence, they are thinly habituated and largely used for fishing and other activities only, thereby reducing the threat of nuclear accidents and its mass effect on local population. Thus, going by the safety consideration, coastal areas suit the planners for setting up of nuclear power plants.

India recently joined UNFCCC cum treaty concluded during Paris Summit on October 2, 2016. India says that the decision to raise the content of nuclear power to overall electric power generation in the country is consistent with its international climate change obligations. Studies point out that global warming and climate change have caused tsunamis and Fukushima tsunami in 2011 is an example of an earthquake-induced tsunami leading to catastrophic nuclear disaster. On the contrary, any serious nuclear accident or exchange of nuclear warheads during war will raise the overall temperature of atmosphere, thereby also contributing to global warming and climate change. It is because of this vicious relationship that agricultural sustainability in India during nuclear disaster assumes significance.

However, post-Fukushima disaster, Paris Climate Change Summits, and SDGs Conferences, a sharp rise in protests and agitations against nuclear plants on a worldwide basis is getting witnessed which is led by different civil society organizations, environmentalists, and conservationists' groups and other scientific associations. More and more concerns regarding marine safety including flora-fauna safety in coastal areas are being expressed, as stakeholders are of the view that presence of nuclear plants nearby coasts leads to release of contaminated material into seawater, thereby leading to contamination of seawater and underground land area.

All such civil society-led resistance movements are preventing policy makers to go ahead with new project constructions on either existing sites or proposed new sites. It has changed the discourse regarding the safety and security of people and other species living close to existing or proposed nuclear project sites world over. In recent years, India too has seen an increase in such protests and prolonged agitations often supported by opposition political parties. Protests at Kudankulam nuclear power plant in Tamil Nadu or Haripur in West Bengal are good examples. There is spurt in resistance to land acquisition exercise for nuclear power plants on the part of farm owners because of disaster concerns. People living in coastal areas are joined by fishermen and other stakeholders and have been resorting to protests and other techniques for stalling the projects on grounds of disaster risks and safety concerns. Hence, it is interesting to watch that cases of protests on a worldwide basis have increased with a serious economic consequence for trade and commerce of global nuclear reactor manufacturing companies.

Emerging Debates on Use of Nuclear Energy

The author is restricted from discussing another aspect of nuclear plant safety discourse, as policy planners influenced by climate change issues have developed attraction for latest technological revolution in power sector, specially the generation of electricity through renewable sources or CNG/LNG-based thermal power plants which is much cheaper than the electricity produced through nuclear mode. If more countries including India were to switch over to CNG/LNG-based thermal power plants for the electricity generation, then nuclear disaster threats would be reduced considerably. Among EU countries, Germany has decided to shut down their nuclear power plants because of climate change and nuclear disaster concerns. In many other EU countries, probable shutting down of nuclear plants is being debated seriously. Even in case of India, such pressures would be generated on the part of policy makers in times to come. Fukushima nuclear disaster proved the assumption completely wrong that onsite accidents are least possible because of advanced warning systems that would shut the nuclear power plant in time. The nature of study does not permit the author to discuss the impact of environmental and disaster concerns on the viability of global nuclear giants such as General Electric, Hitachi, Westinghouse, Toshiba, or Areva on their future business and shutdown threats.

Emerging Trends in Building Disaster-Resilient Indian Cities

All cities need to introduce innovative state-of-the-art technologies for achieving goals of disaster-resilient cities. All future and existing cities need to be built by applying innovative IT that combines safety with comfort. The role of private sectors needs to be increased for developing innovative ideas, solutions, and technologies along with PSUs. There remains a lot of scope for providing training for disaster mitigation and recovery techniques. Federal- and state-level authorities need to ensure ongoing disaster prevention education and training with holding of frequent mock drills with stakeholders.

It can be said that other than handling of flood disasters, cities in India's Punjab still lack infrastructure for making them nuclear disaster-resilient cities as they are located near international borders. There is not much of preparation till date on account of handling of nuclear disasters except certain lockdown SOPs during COVID-19 pandemic period. Because of question of preparations on account of other nuclear disasters, a comprehensive action plan is needed in the coming years. There is a need to make use of AI for developing joint human/robot decision-making. It can move in direction of involving human controllers with UAV in unpredictable and hostile environments. There is an urgent need to impart training in cyber security-related issues.

It is in backdrop of such genuine threats of nuclear disaster that civilian administrations need to take appropriate measures and expedite training of its police forces and medical and other civil defense personnel for meeting challenges of nuclear disaster. Any plan of building Indian cities in recent years must factor in "Nuclear

Disaster Risk Reduction and Disaster Mitigation” plans. The idea of implementing “disaster-resilient cities” shall remain incomplete unless the administration is geared fully and prepared for taking adequate measures in post-COVID-19 period for preventing large-scale causalities in case of a nuclear war with enemy countries or in the event of nuclear strikes occurring close to India-Pakistan border. The need for capacity building for mitigating disaster risk reduction in post-COVID-19 pandemic has increased substantially.

Conclusion

Indian policy makers need to bear that despite technological advancements ensuring zero accidents at nuclear power plants, areas falling under mega nuclear power projects continue to remain prone for being struck with nuclear disasters. The pace at which new nuclear power plants are being set up and becoming operational in India, pros and cons of generating nuclear power, and the entire issue of linkages between development and environmental degradation on account of probable nuclear disaster severely impacting upon agriculture and fishing communities residing in coastal regions has to be borne into minds by policy makers in India. Several studies point out that operating a nuclear power reactor is never entirely free of risk and mere assessments do not eliminate all risk no matter how well the hazards have been assessed, and the case of Fukushima disaster (2011) was an eye opener which confirmed the premise that even advanced countries like Japan could not prevent such disasters from occurring. One may conclude that a huge gap exists between developed and developing world in general and nuclear disaster preparedness in India in particular. The attack and capture of Zaporizhzhia and Chernobyl nuclear power plants in Ukraine by Russian forces, in an ongoing war with Russia since March 2022, have raised alarms over nuclear safety issues world over. India’s record of handling of a biological disaster during COVID-19 pandemic was hardly satisfactory, and it got criticized vehemently at international level over exposure of huge weaknesses in terms of safety, resources, health infrastructure, specialized medicines, vaccines, and medical personnel that killed around half a million Indians. On the whole, going by the past experiences of dealing with natural disasters by NDMA and SDMAs, it needs to bring their functioning more in tune with present realities, especially for dealing with nuclear disasters which until present mostly remains confined to metro cities of the country only. Indian federal and state authorities must fine-tune their energy policies by giving priority to switching over to tapping of vast potentials of solar and wind energy and other renewables on a much larger scale. The idea of reducing its dependence on nuclear energy must be ingrained in all its future energy policy making. On the patterns of EU countries, India also needs to train its population living in cities about NDMG-NRE guidelines which outlines actions that will reduce or eliminate the transfer of radioactive fallout to the food chain following a nuclear emergency. Involvement of youth in disaster-related task need to be taken up on a bigger scale in India.

Abstract

Statistics indicate that India is one of the most disaster-prone countries globally. Despite such vulnerability, disaster management had barely been a mainstream political concern in the country until the COVID-19 struck in 2020. This is rather amusing considering that famine codes were framed and commissions were established during the British era. Since then, a long politico-legal journey culminated in establishing the National Disaster Management Authority (NDMA) in 2005. It was a revolutionary step in the country's institutional arrangement concerning disaster management. Nevertheless, it has failed to have an impactful existence even after one and a half decades. From poor planning to poor execution of projects, rendering committees dysfunctional to formulating disaster management guidelines without any practical implication, the story of the NDMA is far from reassuring. So much so that it has remained almost imperceptible even in the context of the ongoing pandemic. It has confined itself to holding meetings and issuing advisories and circulars and remained out of public view. Instead, the MHA, MoHFW, Prime Minister's Office, etc., have come to the forefront. The Supreme Court too became impatient and pulled up the

authority for its failure in performing its statutory duty. The author briefly introduces the NDMA and outlines its limited role in this pandemic. Its analysis refers to the Comptroller and Auditor General of India and Government Task Force reports on the NDMA. Besides, it draws an analogy with the Federal Emergency Management Agency in the USA. It demonstrates how political interference and inept leadership have rendered it ineffective and thus have deleterious consequences on the country's disaster management. Finally, the author raises some fundamental questions regarding the structure and working of the NDMA and, eventually, the need for this institution.

Introduction

We are still in the midst of one of the deadliest pandemics that have struck humanity. It has left India in a precarious situation. The World Health Organization (WHO) data report that India ranked second in terms of the affected population and third in terms of mortality till the end of January 2022 (WHO, 2022). However, India's tryst with disasters is not something unusual as it has been an extremely disaster-prone country. The Emergency Events Database (EM-DAT), developed by the Centre for Research on the Epidemiology of Disasters, Belgium (Université Catholique de Louvain, Brussels, Belgium, 2022), shows that India has consistently remained in the top three positions in the world in terms of the number of disasters, mortality, and damage caused. In the recent decades, between 2000 and 2019, India reported 321 disasters (Centre for Research on Epidemiology of Disasters (CRED) & U.N. International Strategy for Disaster Reduction (UNISDR), 2020, p. 9). Furthermore, even in 2020, a year dominated by COVID-19, besides the floods resulting in 1922 deaths, Cyclone Amphan accounted for the largest affected population (18 million) and became the second costliest disaster (US \$13 billion) in the world that year (CRED & UNISDR, 2021, pp. 7–9). Despite such vulnerability, it is unfortunate that the disaster management in this country did not become of paramount importance to the government until the COVID-19 occurred.

The central and state governments, nongovernmental organizations, and spirited individuals have played their roles in the fight against COVID-19. Such efforts have been a matter of public scrutiny, debate, and discussion for 2 years now. Nevertheless, the National Disaster Management Authority (NDMA), which should have been at the forefront of this combat, has almost remained conspicuous by its absence in the public discourse. Undoubtedly, the establishment of the NDMA was an essential landmark in the landscape of disaster management in this country. Nonetheless, the author endeavors to understand the significance of its existence for more than a decade and a half. He briefly discusses the legal and institutional development regarding disaster management in this country. Besides introducing NDMA, he

critically analyses its role before and during the pandemic. He draws references from the Federal Emergency Management Agency, the principal emergency management (or disaster management) agency in the USA, its leadership, and its contribution in combating disaster situations. Finally, the author recommends certain changes in its structure and governance to create a more responsible and accountable NDMA.

Legal and Institutional Development of Disaster Management

In India, modern institutional structures dealing with disasters began during the colonial rule in the late nineteenth century. Widespread famines and locust invasions compelled the British Government to set up the Department of Revenue and Agriculture and Commerce in 1871, followed by few famine commissions. The relief codes of the same era were in vogue even decades after independence (Kapur, 2005, pp. 4551–52). The much-discussed law in the context of COVID-19, Epidemic Diseases Act, 1897, was also a similar initiative to fight the bubonic plague in the Bombay presidency (Sherwani, 2020).

A Task Force, constituted by the Ministry of Home Affairs (MHA), Government of India (GoI), to review the Disaster Management Act, 2005 (hereinafter “DM Act”), noted that although administrative procedures existed, a law providing a statutory framework for disaster management operations, supporting organizational structures, and assigning vital legal duties, all of which are necessary for a successful execution, remained elusive (MHAa, 2013, pp. 11–13). Subsequent to the 1999 Odisha Super Cyclone, the GoI constituted a High-Powered Committee (HPC) to provide recommendations for institutional improvements and create disaster management strategies at all levels of governance. The HPC, in its report, suggested a National Calamity Management Act and provided a model for the State Disaster Management Act (Ministry of Agriculture (MoA), GoI, 2001).

The 2001 Gujarat earthquake up the ante for a law on disaster management. Some states like Gujarat (in the post-Gujarat earthquake), Bihar, Uttar Pradesh, and Uttarakhand (now Uttarakhand) enacted laws on disaster management between 2001 and 2005. Meanwhile, there was a paradigm change globally in disaster management: from relief and rehabilitation to prevention and mitigation. The first two World Conferences on Disaster Reduction in Yokohama (1994) and Kobe (2005), Japan, urged the international community toward the same. The 2004 Tsunami provided the final impetus for disaster management legislation (MHAa, 2013, pp. 8–9).

The DM Act virtually revolutionized India’s entire approach toward disaster management. The law unified the response mechanism and envisaged a new chain of authorities from the central to the local levels. The NDMA, along with their state and district counterparts, are the creations of this statute (Second Administrative Reforms Commission (ARC), GoI, 2006, pp. 32–33). Interestingly, the provisions of the DM Act were invoked for the first time to deal with the present pandemic – 15 years after its enactment (Chauhan, 2020).

Brief Introduction to the NDMA, NEC, and Biological Disasters Guidelines

The DM Act constitutes the NDMA as the principal authority at the national level. It functions under the chairmanship of the Prime Minister, *ex-officio*, with a maximum of nine other members “nominated” by the Prime Minister. In addition, the Prime Minister may appoint one of the members as Vice-Chairperson of the NDMA (DM Act, Sec. 3). The NDMA will establish policies, guidelines, and strategies, including the national disaster management plan, and coordinate and monitor their implementation to ensure a prompt and effective disaster response. It will also suggest allocating mitigation funds, taking measures to avoid disaster avoidance, disaster mitigation and readiness, and capacity building to cope with “threatening disaster situations” (*ibid.*, Sec. 6). The NDMA shall be assisted by a National Executive Committee (NEC) consisting of secretaries of 14 central ministries and the Chief of Integrated Defence Staff to the Chairman Chiefs of Staff Committee, *ex officio* (*ibid.*, Sec. 8). The NEC is responsible for supporting NDMA in carrying out its responsibilities and ensuring compliance with the central government’s disaster management directives across the country and laying down guidelines and giving directions to central and state government departments/ministries, as well as the State Disaster Management Authorities (SDMAs) on what steps should be followed in the event of a disaster or danger of the same (*ibid.*, Sec. 10).

Under Section 6 of the DM Act, the NDMA has prepared 30 different guidelines relating to various disasters, including one on biological disasters (NDMA, 2008), which is relevant to the present situation. Indeed, the guidelines highlight the danger of biological disasters, including epidemics and pandemics (*ibid.*, pp. 7–8). They also elaborate the legal and institutional frameworks in dealing with such disasters, especially designating the Ministry of Health and Family Welfare (MoHFW), GoI, as the nodal ministry for handling epidemics (*ibid.*, pp. 12–23). Furthermore, they unequivocally assert that isolation and quarantine can limit or prevent the spread of infectious illnesses (*ibid.*, p. 43). They identify poor public health infrastructure, lack of trained primary health workers at the grassroots level, etc., as impediments in the fight against epidemics (*ibid.*, pp. 29–34). Finally, they propose an implementation plan with different timelines for short (up to 3 years), medium (up to years), and long (up to years) terms (*ibid.*, pp. 113–16).

Innocuous Presence of the NDMA During the Pandemic

On March 14, 2020, the MHA designated the pandemic a “notified disaster” under the DM Act, and consequently, the NDMA was appointed in charge of dealing with the COVID-19 epidemic (NDTV, 2020). Further, on March 24, 2020, in the exercise of its power conferred under Section 6(2)(i) of the DM Act, the NDMA (read as ‘the Prime Minister as its Chairperson’) directed the GoI, state governments, and SDMAs to take strict measures for “social distancing” to stem the spread of the disease and thus to announce “lockdown” of the nation. It also stated that necessary guidelines in

this regard should be issued immediately by the NEC under Section 10(2)(l) of the Act (NDMAa, 2020). Accordingly, the Home Secretary, also being the Chairperson of the NEC, issued orders for the lockdown of the country with necessary guidelines and penal provisions *inter alia* for obstructing or disobeying orders of the public servants, raising false alarm, etc., under the DM Act (Secs. 51–60) and Section 188 of the Indian Penal Code, 1860 (MHA, 2020). They are being modified from time to time as per the requirement (MHA, n.d.).

Curiously, that is all the NDMA has done from then onwards. Without trying anything innovative, it routinely confined itself to holding meetings and issuing some advisories and circulars (NDMAa, n.d.). The advisories included various action points taken in consultation with the Cabinet Secretary and MoHFW, GoI, for the states and union territories. Interestingly, the challenges that subsequently gripped the country, e.g., social distancing, identification of quarantine facilities, building capacity for the frontline personnel, management of the spread of fake news, temporary closure of schools and workplaces, etc., were already mentioned in the February 4, 2020, advisory (NDMAb, 2020). Hence, it is surprising why it took such a long time for the government to identify them and prepare for the emergency.

In the context of COVID-19, the DM Act has become the fulcrum of all actions supported by the Epidemic Diseases Act, 1897 (Hemalatha, 2021). Therefore, the role of the NDMA becomes vital in this context and, as a nodal body, has unparalleled capabilities necessary for disaster control and management to be effective (Ram Mohan & Alex, 2020). COVID-19 was declared a public health emergency by the World Health Organization by late January 2020. However, the NDMA failed to take any comprehensive action, be it a plan of action for mitigation or preparedness as required under the DM Act and its Biological Disasters Guidelines (Sibal, 2020). It did not effectively coordinate with the SDMAs/state governments for the movement of the migrants. It failed even before the second wave of the pandemic, whether regarding the availability of basic essentials, arrangement of livelihood, management of relief camps, or entitlement of statutory minimum relief. Some commentators theorized that the lack of collaboration between the center and the states during the pandemic may be linked to the NDMA's diminished function (Prasad, 2020).

The Prime Minister (of course not in the capacity of the Chairperson of the authority), MoHFW, Indian Council of Medical Research, few Chief Ministers, healthcare experts, and district collectors *sans* the NDMA have been the faces of this massive combat against COVID-19. Former Kerala Health Minister K.K. Shailaja won multiple international awards for her tremendous work in managing the pandemic in the state (Abraham, 2021). From declaring lockdown to imposing a curfew, from surveillance to contact tracing, from testing to creating containment zones, from delivering essential medicine services to vaccinating the population – almost everything was done both at the policy formulation and implementation levels – all important information and works have been performed through the government (Shankar & Pandey, 2021). However, the NDMA largely remains a nonexisting agency. It has disassociated itself from the central

government's obligations and empowered the MHA to give any directives it deems fit in apparent contravention of the Act (Sibal, 2020).

The lockdown advisories ignored that the NDMA is required to recommend guidelines for the "minimum standards of relief" to be provided to the disaster victims in relief camps concerning shelter, food, drinking water, medical cover, and sanitation. The law also calls for *ex-gratia* aid in the event of a loss of life and the restoration of means of subsistence (DM Act, Sec. 12). The Supreme Court also became impatient. In a *suo motu* case (In Re: Distribution of Essential Supplies and Services during Pandemic, 2021), the Court observed that in the light of the tremendous human suffering and loss of livelihood because of the pandemic, "NDMA may consider laying down minimum standards of relief in this regard." The Court, however, clarified that this was "not a direction but a suggestion" that can be looked into by the NDMA (*ibid.*, para. 9). Nonetheless, the NDMA did not act.

Subsequently, in another case (Reepak Kansal v. Union of India, 2021), the petitioners questioned the nonadherence of the statutory duty by the NDMA in providing the guidelines for *ex-gratia* assistance regarding COVID-19 fatalities. The petitioners argued that the usage of "shall" under Section 12 mandates the NDMA to lay down guidelines. However, the GoI reasoned that "shall" is to be considered as "may," and hence the nature of function under the said provision is "directory/discretionary," considering "peculiar facts and comprehensive steps taken by the Union of India" (*ibid.*, para. 6.21).

The Court held that the legislature's intent is evident by using the word "shall" twice in the section, and the same is in tune with the Statement of Objects and Reasons for the enactment of the DM Act and the functions and powers of the NDMA. Hence, the NDMA has a statutory duty to recommend guidelines. Ordinarily, statutory enactments must be read according to their plain meaning if the wording of the provision is clear and unambiguous. The beneficial provisions must be interpreted literally to fulfill the legislative objective rather than defeat it (*ibid.*, para. 10.1). Furthermore, if any authority fails to carry out its statutory obligation, the Court might issue a writ of mandamus to compel compliance (*ibid.*, para. 7.3).

The Court found "nothing is on record that any decision/guidelines has/have been issued by [NDMA]." It rapped the authority for its failure in performing its statutory duty. It issued a writ of mandamus for recommending suitable guidelines for *ex-gratia* assistance in the event of a death due to the COVID-19 pandemic (*ibid.*, para. 10.4) within 6 weeks following the date of the decision (*ibid.*, para. 16). However, the Court left it to the "wisdom" of the NDMA to decide the "reasonable amount," considering various factors (*ibid.*).

Moreover, in this fast-communicating world with an ever-increasing number of smartphone users on social media platforms, where information spreads at a breakneck speed, the NDMA has failed to utilize the potential of communication even to a satisfactory level. For example, information on the Facebook page of the NDMA is very basic, mostly about dos and don'ts regarding COVID-19 (NDMA Facebook, n.d.). Instead, the NDMA could have used such platforms to inform people timely and accurately of the agency's activities, actual state of affairs in the country, activities

carried out in different states, key statistics, success stories, important announcements, webinars, and interactive sessions by the members and other experts associated with it. Even to this date, the only COVID Impact and Response Report regarding India available on the NDMA website is for the period between January and May 2020 (NDMA, 2021). Further, for the reasons known best to the authority, the case studies pertaining to various Indian states are available in six official UN languages instead of Indian languages (NDMAb, n.d.)!

Exploring NDMA's Existential Significance

Globally, disaster management is no more regarded as an ancillary act of regular administrative functions of the state but a specialized activity. Until this pandemic happened, disaster management had not bothered the political class much in this country. Apart from few issues like air pollution in Delhi, it has barely become an electoral agenda (Kandhari, 2020). Naveen Patnaik is rather an oddity under whose leadership Odisha has significantly improved in mitigation and preparedness since the Super Cyclone days and weathered this pandemic and a series of sea storms (Datta, 2020). So, it is unsurprising that the NDMA has very little "authority" in actually calling shots. The constitution, treatment, and performance of the NDMA raise its existential significance.

The very structure of the agency appears political. Besides the fact that it is headed by the Prime Minister of the nation, quite curiously for the NDMA members, there is neither any qualification attached to their nomination nor any appointment process prescribed under Section 3(2) of the DM Act. In a way, the DM Act legitimized appointing political appointees, leaving the system vulnerable to political abuse (Sarkar & Sarma, 2006, p. 3762). A comparison could be the National Human Rights Commission (NHRC). Under Section 3 of the Protection of Human Rights Act (PHRA), 1993, NHRC is a combination of judicial and nonjudicial members. The judicial members shall be from the higher judiciary, and even the nonjudicial members must have the knowledge and practical expertise in human rights issues. It also provides for the tenure, appointment, and removal of the Chairperson and the Members (PHRA, Secs. 4, 5 & 6). We may further consider the instance of the Gujarat State Disaster Management Act, 2003 (hereinafter "Gujarat Act"), which predates the DM Act. It established the Gujarat State Disaster Management Authority (GSDMA) with a good blend of senior ministers and bureaucrats, including the Director-General of Police and the State Relief Commissioner (Gujarat Act, Sec. 7). The political character of the NDMA is not unfounded. After the change of Government at the center in 2014, all Members, including the Vice-Chairman, but one resigned (The Hindu, 2014). Although India was reeling under a spell of disasters, the agency remained dysfunctional (Sethi & Makkar, 2014).

Since the establishment of the NDMA, India has suffered some of the worst disasters; yet it has not done anything worthy to be mentioned. The Comptroller and Auditor General (CAG) delivered a damning report on the NDMA's performance to

Parliament in March 2013 (MHA_b, 2013). According to it, the NDMA had neither knowledge nor control over how disaster management initiatives in the states were progressing. Its initiatives were in a state of disarray. In 2008, the NDMA launched several mitigation initiatives around the country; however, they were either discontinued or redesigned due to poor planning. The report further pointed out that there is no clear demarcation of functions among the NDMA, NEC, and MHA. It noted with dismay that the very idea of enacting the DM Act was to shift focus from disaster response to mitigation. Nevertheless, the execution of almost all the mitigation projects carried out by the NDMA was unsatisfactory (*ibid.*, 28–37). Projects regarding national vulnerability to floods and earthquakes have remained incomplete. Experts believe that if such initiatives had been effectively completed, the devastation in Uttarakhand in 2013 might have been significantly reduced (Shrivastava, 2013).

The CAG found high vacancies extending from 33 to 60% of the sanctioned 124 posts at the end of different financial years within the review period (2007–12), hindering the authority's work. The NEC has failed to meet even for a single time between 2008 and 2012 (MHA_b, 2013, p. 41). The absence of strong and able leadership plagues the authority. As the Prime Minister is the Chairperson, the day-to-day management of the NDMA falls on the Vice-Chairperson. The government failed to rise above the political interests and provide the authority with a strong driving force (Bhalla & Bagga, 2013).

After 7 years of existence, the NDMA was found to have no working plan. It took a rap from the Supreme Court (Swaraj Abhiyan – (I) v. Union of India, 2016) to prepare and publish the National Disaster Management Plan after more than a decade of the NDMA's existence. An updated plan was available in 2019, which details the roles and responsibilities of various ministries/departments of the central and states (National Disaster Management Plan, 2019, pp. 235–48). However, we do not know how the NDMA will ensure the actual working of this plan through effective coordination.

Similarly, the Guidelines on Biological Disasters have implementation datelines, but in practice, neither those datelines were complied with nor any action has ever been initiated for such noncompliance. All suggestions and action points remain excellent on paper with no impact on the ground. The consequences are visible as the state was caught napping even at the fag-end.

Furthermore, the Annual Reports indicate a variety of work carried out by the NDMA: from disaster risk mitigation projects to capacity building to mock exercises and awareness generation (NDMA_c, n.d.). However, all these operational activities are carried out with the approval and support of the central government. That being the case, and even during this mega-disaster, if the agency has to remain behind the curtains, how do we justify creating a separate statutory authority outside the government? In the author's opinion, all those works could have been accomplished in the same manner with a disaster management division within the MHA – as it existed prior to 2005. Hence, the entire edifice of the agency is an illusion and is not money's worth.

Well aware of the ailments of the agency, the UPA government had constituted the Task Force for reviewing the DM Act. The report of the Task Force has, inter alia, recommended restructuring the NDMA. The number of full-time Members was reduced to four who shall have the expertise of disaster management, science, or public policy, as well as credible accomplishments in these fields (MHAa, 2013, p. 63). However, it does not mean that we should fill the positions with retired military careerists. We have to realize that disasters are not wars – there are civilian problems for which military personnel are not necessarily well trained. Disaster response could be a military activity for which the National Disaster Response Force (NDRF) has been established under Section 44 of the DM Act. However, other aspects of disaster management require specialists, including healthcare professionals, scientists, social scientists, engineers, and policymakers, who are trained to deal with civil protection issues. Similar to the Members of the NHRC, it also recommended the selection process, tenure, and other terms and conditions of service for the Members of the NDMA. Additionally, like the GSDMA, to bring political heads and bureaucrats together, it suggested Ministers of Home Affairs, Defence, Finance, Agriculture, Urban Development as *ex-officio* Members of the NDMA (*ibid.*, pp. 62–63). These efforts were undertaken to ensure that competent and professional persons assume the posts at the helm of affairs. Therefore, in addition to the skills and abilities of a generalist manager, emergency managers also require mastery of a body of professional knowledge. As the NEC is practically dysfunctional, the National Crisis Management Committee takes over during a crisis. So, it suggested the abolition of the NEC (*ibid.*, pp. 64–65). It was evident from the orders issued by the Home Secretary during this ongoing crisis.

Let alone initiating actions to incorporate the recommendations of the Task Force, the importance with which disaster management is viewed politically in our country is evident from the attitude of the BJP Government at the center. The position of the Vice-Chairperson of the NDMA has been downgraded from the rank of Union Cabinet Minister to the Cabinet Secretary to the Union Government. In fact, the post has been virtually abolished as there has not been any Vice-Chairperson after Mr. Shashidhar Reddy. Similarly, the rank of other Members of the NDMA has also been reduced from Union Minister of State to the Secretary of the Union Government (Zee News, 2014). In such circumstances, it may well be possible that the present Government has scant interest in this organization, and therefore, in the context of COVID-19, NDMA has been relegated to an inconsequential entity, while the Union Government with the Prime Minister at the helm of affairs is at the center of all activities for political interest.

With no human resources at its disposal; an utter confusion that the DM Act has created between the functions of the NDMA and NEC under Sections 6(2) and 10(2), respectively; and the fact that the NEC is virtually redundant – the only way for this national authority to make its presence felt on the ground is through NDRF. It is a specialized response force and has arguably become the face of disaster management in India alongside the Armed Forces. Even though general superintendence, direction, and control of the NDRF lie with NDMA under Section 45 of the DM Act, the

Director-General of the force reports to the MHA (MHAa, 2013, p. 54). Once again, the NDMA turns out to be a ‘notional authority.’

Comparability to FEMA in the USA

Having discussed the NDMA at length, it is pertinent to explore the US experience with the Federal Emergency Management Agency (FEMA), akin to our NDMA. Not only like India, the USA is a highly disaster-prone country, several expert committees in India have also referred to the FEMA in their reports. For example, the High-Power Committee (HPC) constituted by the GoI in 1999 for suggesting institutional reforms and preparation of disaster management plans at the national, state, and district levels discussed the FEMA’s incident command system: the agency’s usage of the geographic information system (GIS) technology and disaster medical assistance teams (MoA, 2001, pp. 93, 142). In its third report on Crisis Management, the Second Administrative Reforms Commission noted the importance of the FEMA in dealing with disasters in the USA (ARC, 2006, p. 40). The Task Force, in its report, expressed apprehension that the idea behind NDMA “was to create an autonomous organization similar to that of FEMA.” However, it turned out to be “markedly different from FEMA in terms of its functions, reach and tasks assigned” in practice (MHAa, 2013, p. 41). It also appreciated the high level of autonomy enjoyed by the FEMA in its operations (*ibid.*, pp. 28–30).

The FEMA was established by Executive Order 12127, signed by President Jimmy Carter in 1979 (Bea, 2012, p. 107). The FEMA was obligated mainly to (1) organize federal resources, (2) collaborate federal efforts with those of state and local governments, and (3) oversee public and private sector disaster response activities (Schneider, 1998, p. 38). Further, under Robert T. Stafford Disaster Relief and Emergency Assistance Act of 1988 (popularly called “Stafford Act”), the principal emergency management legislation in the USA, the FEMA is given the responsibility to organize the government’s wide range of emergency mitigation, preparedness, and response efforts (Sylves, 2008, pp. 80–81). According to the agency’s website, as of July 2021, it has more than 20,000 employees countrywide, including its headquarters in Washington DC, 10 regional offices, and various training centers (FEMAa, n.d.). Nonetheless, the FEMA is not a self-contained functioning entity capable of mobilizing resources to respond to catastrophes but a collaborating one that assigns other federal agencies to assist state and local governments with their resources (Wise, 2006, p. 307).

The success of such a public organization depends on able leadership and political will combined. Recognizing the importance of proactive steps in disaster management, President Bill Clinton appointed James Lee Witt as the Director of the FEMA in 1993. He was FEMA’s first Director with experience in emergency management. Clinton conferred the FEMA with enhanced autonomy, and Witt became instrumental in bringing about various changes both outside and inside the agency. Restoring the FEMA was one of the Clinton administration’s most remarkable achievements (Waugh Jr., 2006, p. 12). Witt stressed the customer training of all

the employees. As a result, the agency's role became more collaborative than before. The FEMA also took up an ambitious project called "Project Impact: Building Disaster-Resistant Communities" to empower communities by asking them to identify hazards and develop a plan to mitigate them by including all community stakeholders. These changes did not simply happen on paper but delivered positive results. As a result, the FEMA effectively dealt with various disasters throughout the decade, including the Midwest floods (1993) and the California earthquake (1994) (Haddow & Bullock, 2003, pp. 9–12).

As soon as George W. Bush took over, he neutralized the gains reaped during the Witt-Clinton era. He eliminated funding of the popular Project Impact. Significant structural changes also happened during his tenure. Following the 9/11 terrorist attack, the objective of disaster management in the country primarily shifted to terrorism. The US Department of Homeland Security (DHS, commonly called "Homeland Security") was established following the passing of the Homeland Security Act of 2002 to improve coordination among the various federal agencies responsible for law enforcement, disaster planning and recovery, border security, and civil defense. As a result, the FEMA became part of the DHS in 2003. Consequently, *de facto* cabinet status enjoyed by the FEMA Director during Clinton's regime ended – a move criticized by some experts (Kettl, 2006, p. 283). Now the DHS has the central role to play in the emergency response. As a result, the FEMA's budget was cut, staff and resources were transferred to counter-terrorism initiatives, and employee morale plummeted (Waugh Jr., 2006, p. 17).

Bush also adopted the traditional approach of appointing political persons at the helm of the affairs in the agency. Consequently, the FEMA was consecutively headed by two Directors who had no experience in disaster management. Joe Allbaugh, a campaign manager of Bush, was followed by Michael Brown, a Commissioner for the International Arabian Horse Association (Haddow & Bullock, 2003, p. 13). They had to resign but not before inflicting unimaginable damage to the prestige of the FEMA. Brown would subsequently face the Congressional Select Bipartisan Committee to Investigate the Preparation for and Response to Hurricane Katrina, constituted immediately after the disaster (Schneider, 2015, p. 178).

However, the Katrina fiasco compelled Congress to enact the Post-Katrina Emergency Management Reform Act of 2006, reinstating the FEMA as the lead federal agency within the DHS, taking charge of managing all kinds of disasters. It also established new requirements for the FEMA personnel, stating that the FEMA Director must have emergency management credentials with executive leadership and management skills. In addition, other top FEMA officials must know and be familiar with emergency management competencies (*ibid.*, p. 24).

During President Obama's tenure, the FEMA recovered from its tarnished image under the Bush administration. Obama's FEMA Director Craig Fugate is primarily regarded for refocusing the agency on community preparation and turning it around (Nilsenella, 2017). Even Donald Trump's appointee, Brock Long, was touted by many experts and critics as a well-known professional in the field (Hart, 2017). Unfortunately, in his brief tenure, he faced severe problems because of an incompetent President who did not recruit key staff members in the DHS and, being

immigration-focused, orchestrated budget-cut for the FEMA (Nilsenella, 2017). COVID has been the most significant challenge that the FEMA has faced to date. Acting FEMA Director Peter Gaynor was called on to manage the pandemic. Although many had reposed faith in Gaynor's ability (Barr, 2020), the FEMA failed to rise to the occasion appropriately with Trump as the broad leader.

The FEMA launched its Public Assistance (PA) Grant Program in response to the national emergency declaration for COVID-19 to assist state, territorial, tribal, and municipal government entities and certain private nonprofit organizations in promptly responding to and recovering from the pandemic. While some of those programs, although meant for the victims eventually, are provided to the state, local, or tribal government, there are an array of programs targeted towards individuals. Many such Federal assistance programs provided under the Stafford Act are either of fixed dollar limits or percentage costs (FEMAb, n.d.).

In addition to the PA Grant Program, no major assistance programs targeting individuals were declared in connection with the COVID-19 pandemic. Governors had requested additional disaster assistance programs to be activated in their states, so this was a direct conflict with their requests. The FEMA's Crisis Counseling Program, which provides mental health counseling to catastrophe survivors – an essential but rather a tiny program given the size of the pandemic – is the sole individual support that was approved for states (Calabro & Patton, 2021, pp. 1–2).

Trump's government was severely criticized for political bias on various occasions. Politicians were accused of funneling disaster funds to preferred districts while ignoring the constituencies of their opponents. President Trump, according to the Denver Post, "is treating life-saving medical equipment as emoluments he can dole out as favors to loyalists." A comparison of the first round of the Paycheck Protection Program, a loan program launched in 2020 to assist small businesses to continue paying their workers, shows that businesses in states that supported Trump received more generous government assistance than those supporting Hillary Clinton (Firey, 2020). Justifiably, some critics labeled Trump as the "worst President in the history of the US" for his role in mismanaging the pandemic (Boot, 2020).

When Joe Biden assumed power, he made a few adjustments to the FEMA's programs. For example, in housing projects, the FEMA financing through the PA program normally pays 75% of the eligible costs, allowing the remaining 25% to be covered by governments and nonprofit organizations. On January 21, 2021, President Biden signed an executive order authorizing the FEMA to cover 100% of the cost of certified noncongregate sheltering in hotels and motels across the country, including for homeless persons and occupants of congregate living facilities (Calabro & Patton, 2021, p. 2). Therefore, the FEMA was allowed to apply retroactively for total funding of relocating homeless people to hotels and motels under President Biden's directive. From the beginning of the pandemic in January 2020 until September 30, 2021, state and local governments would be reimbursed in full for any authorized noncongregate sheltering expenditures (*ibid.*, p. 3). This was a welcome development and would also benefit people experiencing homelessness during other major disasters.

Conclusion – The Way Forward

Considering the structure and performance of the NDMA, the agency must be vested with more authority and autonomy than it is. We can opt for some of the suggestions offered by the Task Force for restructuring the agency. There is an immediate need to have a disaster management specialist appointed as the Vice-Chairperson of the NDMA, who would be the face of the agency and responsible for its activities. The US experience is relevant in this regard. Like the FEMA, the NDMA deserves a larger workforce who would coordinate actions with SDMAs/state governments and work toward implementing the national plan and/or the guidelines. The agency must increase its visibility among citizens, both through its activities and social media tools. The NEC may be scrapped as it has not done anything mentionable to date. The community is the first responder; therefore, it is imperative to empower communities as Witt did through Project Impact. Capacity building remains one of the NDMA's various statutory functions, which it cannot afford to ignore. Disasters in general and the COVID-19 combat in the recent times have demonstrated that narrow political considerations or inapt political leadership would eventually lead to defeat. Some States like Kerala and Odisha have earned wide accolades for their successful actions and have emerged as "models." Why can't someone heading the operations in those states be brought to lead NDMA? The choice is ours – whether to go the Clinton way or Bush way. Otherwise, the NDMA will forever remain conspicuous by its absence, similar to its situation during the present crisis.

Abstract

With the onset of Covid-19 as the biggest health disaster globally, the world witnessed the new phenomena of lockdowns, social isolations, containment zones, and quarantines. Affecting all dimensions of life be it social, economic, or health, this disaster has exposed the socioeconomic inequalities that will adversely impact the existing vulnerable sections of the population based on caste, class, ethnicity, religion, race, disability, and gender.

The existing gender inequalities will be exacerbated affecting women the most that stand at the intersection of such ascribed identities. “None of us will see gender parity in our lifetimes, and nor likely will many of our children. That’s the sobering finding of the Global Gender Gap Report 2020, which reveals that gender parity will not be attained for 99.5 years” (WEF, Global gender gap report

D. Brahmachari (✉)

Janki Devi Memorial College, University of Delhi, New Delhi, India
e-mail: debahuti@jdm.du.ac.in

2020, Insight report, 2020). Similar disease breakouts in the past have amplified gender implications, and thus the current pandemic will inexplicably affect women and girls. It is against this backdrop that this chapter tries to look into the irrevocable impact of the pandemic on women's health especially reproductive, sexual, and mental health concerns. Postponement and restrictions on essential maternal services, diversion of health resources, mental distress, and limitations of family planning services are some of the major concerns. It is crucial to underline the inherent nexus of health and gender inequality which is being amplified due to Covid-19 and will worsen it further. Thus, the study concludes by outlining the need for proactive inclusive public health responses at the earliest.

Gender-Differentiated Impact of the Pandemic

Pandemics in the past have revealed that the worst off have always been women in terms of loss of every kind. Disasters over the years have demonstrated that certain sections of the population are worst affected. The impact of disasters is largely shaped by gender dimensions. The impact over male and female distinctively needs to be understood through a gender analysis. The socially constructed manifestations during disasters further add on to the prevailing vulnerability of women. Using the gender lens highlights a “great deal to do with their ability to cope with and bounce back from the effects of disasters” (IRP, 2007).

Gender-differentiated impacts due to disasters have been long identified in history, and hence its understanding will lead to sustainable recovery measures. The Covid-19 disaster has led to unprecedented crises all across the world. The failure of health structures and systems was highlighted at the forefront. The biological facets of the virus gradually engulfed nations and exposed the multiple layers of vulnerability within the societies. “The United Nations Secretary General has called the current situation a human crisis” (Mizutori, 2020). Complex in its nature, the pandemic has uncovered the various socioeconomic determinants of inequalities which have an overarching bearing on the vulnerability parameter. The world is continuously struggling due to this health disaster that has affected all dimensions of life. Primarily the urgent crisis is the exacerbation of the existing gender inequalities. The worst exposed are women and girls, whereby the pandemic has widened the existing gender inequalities. Outbreaks in the past have had gendered implications ranging from socioeconomic repercussions, risk of exposure, to rise in individual vulnerabilities. Covid-19 has disrupted the world in many ways, especially with adjournment and constraints on essential reproductive and sexual services. Public health responses have had limited responses toward the gendered

impacts of such health disasters. Hence, it is necessary to highlight the impact of Covid-19 on gender equity which is being amplified and will worsen the existing vulnerabilities.

Women are more susceptible to health risks as outlined by several researchers in the past. In the case of pregnancy, the risk factors intensify especially in terms of transmission of diseases. The health of the mother is directly proportional to that of the baby; thus the immunological responses during the pandemic are of great concern (Wastnedge et al., 2020). The Covid-19 virus directly impacts the respiratory system, thus making pregnant ladies more vulnerable as there is a reduction in total lung capacity (Goodnight & Soper, 2005). Physiological studies in the past have established the long-lasting detrimental effects on both the mother and the child (Liu et al., 2020). Though less research has been done to identify the definite trends of the Covid-19 virus on mothers, lessons from the past have reported adverse maternal mortality rates in the case of SARS and MERS (Di Mascio et al., 2020). As a result, this health disaster “could cause fetal growth restriction, preterm birth, and prenatal mortality” as witnessed in the case of past viruses (Wastnedge et al., 2020).

As Covid-19 unfolds in its different variations, it leaves millions of women behind who have no access to any sexual and reproductive health rights that are inherently human rights (UNICEF, 2021). Both the direct and indirect effects of the pandemic need to be analyzed with a gender lens in order to redress the gender disparities in these unparalleled times.

The Missing Link

The Sendai Framework for Disaster Risk Reduction was a conclusive push in 2015 from countries which were worst affected due to these epidemic disasters (Mizutori, 2020). Human health became the focus of governance with great concern and specific roles for various stakeholders in disaster risk reduction. The framework demanded the need for buoyant health systems to reduce morbidity and mortality (Selmi & Murray, 2015). Pandemics and epidemics were given a new definition within the disaster framework extensively. 2015 was earmarked as the year of global significance with the Sustainable Development Goals (SDGs) setting its path for future coherence along with other global policy mechanisms. A synergistic approach between sustainability and disaster risk reduction (DRR) was a significant outlook of this era (Zaidi & Fordham, 2021). Health has been at the core of such an approach, whereby the vulnerable sections are the worst off in case of disasters of any kind. Covid-19 has once again echoed the contemporaneous issue of missing out the gender lens within leading policy frameworks. The explosion caused by this disaster has led to multiple consequences that has an undulating effect, primarily on women. “Absence of a gender considerate approach to DRR” (*ibid*, p.2) fails to build on a long-term inclusive sustainable development outlook.

Lessons from the Past

“2020 was expected to be a year for reviewing achievements and accelerating progress in the implementation of the Beijing Declaration and Platform for Action 25 years since its adoption” (Grown & Paramao, 2020). The virus in the form of a public health disaster has stalled all efforts toward the empowerment strategies for the vulnerable sections. Healthcare structures have been distorted all across the world, whereby women and girls face disproportionate health risks. The pandemic has been expected to exacerbate the existing gender gaps especially in the case of access to resources. With the second wave breaking the existing health systems, the developing countries are threatened to cope up with the existing limited resources and weak health systems.

Past outbreaks of similar disasters have outlined the gendered norms where women were the worst off. Epidemics like SARS (2003), Ebola (2014), and Zika (2016) outbreaks highlighted the deepening of gender inequalities and the diversion of essential resources leading to high rates of maternal mortality (Wenham et al., 2020). Sierra Leone has been an example which is still fighting back to achieve its development goals in relation to maternal mortality rates post the Ebola crisis (Ghouaibi, 2021). Lessons from Ebola showed a decline in the use of essential services, such as care facilities, contraception uses, and family planning measures. The outbreak led to 3600 neonatal and maternal deaths along with stillbirths (Sochas et al., 2017). Health disasters push future generations into stake in the absence of gender-based resilience measures by the governments. “We think the collateral damage of the epidemic is higher than the damage caused by the epidemic itself” (Beech, 2020).

Lack of decision-making power is an inherent cause which limits women to make choices for their well-being. Absence of autonomy restricts women to even voice out their own reproductive and sexual choices. Disasters in history have highlighted the deeply gendered aftermath which leaves behind the most vulnerable sections of the society. The world is characterized today by social isolations and lockdowns which further intensify the barriers toward gender equity. “People whose human rights are least protected are likely to experience unique difficulties from COVID-19” (Grown & Paramao, 2020).

Impact of Disasters in Low- and Middle-Income Countries (LMICs)

The vulnerability toward the infection is high due to “multiplicity of social, economic, cultural and institutional factors that make them the worse off (*ibid*).” The new mutations are turning out to be deadly which will lead to disruption of sexual and reproductive health in LMICs leading to surge in MMR. The Guttmacher study predicted 1.6 billion women of reproductive age will be impacted, whereby 49 million women will lack contraceptive services leading to 15 million unintended pregnancies (PFI, 2020, pg. 4). With the health systems grappling all across and lack of access of care, 1.7 million expected mothers and 2.6 million newborns will be

under threat (*ibid*). LMICs of Asia, Africa, Southern and Eastern Europe, Latin America, and the Caribbean have seen in the past the commotion of essential health services along with the rise of HIV/AIDS, other sexually transmitted diseases (Tang et al., 2020), and high mortality and morbidity. Moving toward a sustainable path of development, the 2030 agenda focused toward the “leave no one behind” goal, whereby the disadvantaged and vulnerable sections of the population had to be the focal point. The past experiences have once again outlined the impact of Covid-19 in low- and middle-income countries, especially those of the indigenous sections.

Impact on Reproductive and Sexual Rights

Lockdowns brought back families together, and work from home became a norm even when lockdowns were over. The migrant workers refused to return home in view of uncertainty, but this situation came heavily on the reproductive and sexual lives of women both urban and rural. The new normal has disrupted the access of essential reproductive and sexual services available to women in all parts of the world “at a time when women and girls need these services most” (Beech, 2020). The overwhelming breakdown of health infrastructures has resulted in collateral damage to the vulnerable sections especially women leading to higher risks in the future. Disasters have always had an overarching impact on maternal services largely limiting women’s access to safe deliveries, contraceptives, and other sexual and reproductive health services. Diversion of essential services toward the pandemic responses limits women’s access, thus further deepening the existing inequities. The following section tries to explore the key areas that have been impacted due to the de-prioritization of sexual and reproductive services in the wake of one of the biggest health disasters.

The world has been grappling under the severe economic crisis as a result of the pandemic, leading to rising unemployment and loss of jobs for both men and women. The informal sector has been hit largely with 70% of the workforce being led by women in the Asian subcontinents (ILO, 2018). Job losses and lack of income shape the fertility preferences for families largely. Women tend to delay pregnancy choices keeping in mind the economic burden faced by the family. The magnitude of the burden is more for the sections of the population who suffer systematic health and social inequalities (Lindberg et al., 2020). Child-bearing preferences take a back seat keeping in mind the larger socioeconomic challenges in times of disasters. The United States witnessed “one third of women deciding to get pregnant later or have fewer children” (*ibid*).

Patterns of contraception usage have seen a downfall during such humanitarian crisis in the past. Loss of income directly limits choices of obtaining contraceptives. UNFPA has “projected that more than 47 million women could lose access to contraception leading to 7 million unintended pregnancies as a result of the Covid-19 crisis” (Aly et al., 2020). The impact of contraception disposal largely governs fertility decision-making choices for women. The marginalized sections bear the brunt of the de-prioritization of such essential services. The fear is magnified when

traditional methods fail leading to high percentage of unintended pregnancies. LMICs have been characterized largely with the disruption of supply chain of essential health services like contraceptives (Riley et al., 2020). Large family planning service providers (clinics) have been shut in India in the wake of nationwide lockdowns thus aggravating gender-based health disproportions (Stopes M International, 2020). Thus, neglect of the impact of such health disasters on essential time-sensitive sexual and reproductive services will exacerbate existing gender gaps.

Confinement measures, traveling restraints, and social isolations all across the globe have created barriers for the access of essential healthcare. Shutting down of healthcare centers/clinics and diversion of medical personnel toward the pandemic demands have adversely affected prenatal care, maternal care, and postnatal care. With even a decline of “10% coverage of health care services for mothers and new-born, the death toll would rise to 1.7 million pregnant women and 2.6 million new-borns experiencing complications” (Riley et al., 2020). Due to fear of infection, women tend to do away with their expected maternal visits at hospitals or clinics. Reduction in personal health visits has been identified as a major concern with respect to continued barriers in relation to maternal healthcare services. A study by the Population Foundation of India underlined that with the lockdown, Village and Health Nutrition Days (VHNDs) and outpatient department treatment (OPD) were disrupted largely in both urban and rural areas of India (Nguyen et al., 2021). The primary health centers were lacking in supplies due to travel restrictions, pushing women into greater dangers associated with reproductive and sexual healthcare.

Further medical troubles to women during the pandemic were caused by the socioeconomic deprivations faced by her at every level. Large-scale recession and growing economic insecurities have impacted women largely. Loss of jobs and absence of social security have been largely disrupting the access of reproductive and sexual health services. Absence of health insurance will largely disrupt the access to healthcare with large-scale job losses. The burden of unpaid care has pushed mothers to quit jobs twice as compared to fathers (Burki, 2020). Doing away with contraceptives and other family planning measures in the case of loss of income has been the major fallout of the pandemic affecting fertility preferences (Lindberg et al., 2020). Further, with a decline in purchasing power, regular traveling to health centers is also avoided to cut down on the costs.

“Socio economic deprivations is a clear driver of maternal morbidity and mortality and an appositive gradient has been observed between deprivation indicators and a range of adverse maternal child health outcomes” (Wastnedge et al., 2020). Further, the socioeconomic dimensions are entwined and will deeply “compound pandemic’s impact on sexual and reproductive health” (Lindberg et al., 2020). Gender gaps are exacerbated due to socioeconomic crisis, whereby the Covid-19 disaster has once again pushed women into a vulnerable status.

Among the major threats during such disasters are the rising numbers of victims of IPV (intimate partner violence). The condition of women and girls in conflict-struck areas and disaster-prone areas is extremely fragile. Adding to which is the rising danger of sexual violence which systematically adds up to the existing

discrimination. The pandemic has confined women and girls with the perpetrator at home leading to an upsurge in gender-based violence. “Women- and it is predominantly women who are victimised- are confined to isolated homes with abusive partners whose coercive and physically violent tendencies are enabled and further inflamed by economic stressors... Abuse thrives in silence and beyond closed doors” as stated by Laura Kuester, executive director of Help In Crisis (Gourd, 2020). In China’s Hubei province, the rate of domestic violence tripled with nationwide lockdown orders (Ghoshal, 2020). Rising incidents of IPV have resulted in direct consequences for physical and mental health, “leading to higher morbidity and mortality for co-occurring diseases” (Miller & Mccaw, 2019).

The immediate ramification is the rise in adolescent pregnancies and unwanted forced teenage pregnancies due to sexual violence. Women’s susceptibility to abuse is characterized through multifarious elements ranging from verbal to physical violence, from sexual to psychological forms that impact one’s future disproportionately. Past epidemic disasters have classified the rise in teenage mothers due to increased sexual abuse or “as negative coping strategy by girls” (Connor et al., 2020). With large-scale school closures, lack of education, and economic inconsistencies, young girls are forced into forceful marriages leading to unwanted pregnancies. Such exploitative basis of relationships has led to the rise of sexually transmitted diseases like HIV/AIDS (*ibid*). A study by WHO reported that victims of abuse would be prone to sexually transmitted diseases 1.5 times more and mental depression simultaneously (Ghoshal, 2020). Lack of contraceptives and limited health services may lead to a rise of teenage pregnancies up to 11% (UNFPA, 2020). In 2013, countries in Latin America and the Caribbean adopted the Montevideo Consensus on Population and Development prioritizing access to sexual and reproductive health services along with population dynamics in sustainable development (IISD, 2013). With the onset of Covid-19, the commitment toward comprehensive sexuality education took a back seat (UNFPA, 2020) leading to the de-prioritization of gender-based violence. Adolescent fertility has been a soaring concern in disaster-prone regions especially LMICs, and the pandemic has once again drawn the immediate attention to focus to mitigate such risks.

One of the prime and essential time-sensitive health service is the right to choose to give birth, that is, abortion rights. The pandemic has been a big blow toward abortion rights of women, whereby confining it to “nonessential healthcare” (Jones et al., 2020). Diversion of medical care toward the pandemic needs have created barriers for women to access abortion facilities all across. “Barriers to abortion may result in an increase in births from unintended pregnancies” (Lindberg et al., 2020). This threatens the lives of many women, especially young teenagers who are forced into such accidental births. Diversion of resources legally has delimited the access to safe abortion facilities largely all across the globe (Paul, 2021). One cannot delay the time line of abortion requirements as with each week of gestation the risk and complexities rise (Bayefsky et al., 2020). With delays the dangers of unwanted or enforced pregnancies are inevitable resulting in burdening an already under-resourced healthcare system during the pandemic times (Connor et al., 2020).

The past has portrayed several episodes, whereby sexual and reproductive health services like maternal care, safe abortion facilities, and birth control have been clamored upon. Largely the LMICs are impacted the nastiest as was seen in the case of Zika and Ebola virus disaster. With large-scale in-house lockdowns an “additional 3.3 million unsafe abortions” (PFI, 2020) is predicted as an aftermath of Covid-19. The health disaster has eroded millions of women and girls from their basic access to healthcare services. UNICEF has demanded governments immediately to reconstitute and reinforce the maternal and reproductive healthcare services.

Mental or Emotional Health

The physical impact of the virus has been the focal point of core research currently, neglecting the adverse impacts of mental or emotional health disorders. Unfortunately, the global health stressors in the pre-Covid times have been characterized with anxiety and depression as two of the foremost causes under disease burden (GBD, 2019). Health budgets across the world have been a glaring example of such causes with meager investments being done in the area of mental health. India as compared to Bhutan (2.5%) and Nepal (1.6%) has the lowest public health spending amounting to 1.02% of GDP (NHP, 2018). Studies during the pandemic period have highlighted the rise of depressive disorder and anxiety disorders largely in countries where the pandemic has hit the most (Santomauro et al., 2021). The existing inequalities and varied range of social determinants have highlighted that women are at the receiving end of the health crisis.

Large-scale economic burden and loss of jobs, burden of unpaid care round the clock, lack of essential maternal and neonatal healthcare facilities, and rising cases of gender-based violence have escalated the mental stress of women. The axis besides which the Covid-19 contagion is widening health disparities needs to focus on the gender-specific dimensions (Connor et al., 2020). Centers for Disease Control and Prevention stated that “women on average report more physical and mental unhealthy days per year than men despite utilizing more preventive care services outside the pandemic” (CDC, 2013). Disaster data in the past has highlighted the long-term effects of mental stress and is likely to be influenced highly by gender even now. The subsequent gendered structural inequalities enforce women to follow social roles without adequate social support. In times of distress, the overburdening due to such roles exacerbate nervousness and stress parameters of women. “Sociological studies hypothesize several sources of chronic stress: empathetic vicarious stress, workforce participation, caregiving responsibilities and lack of social support” (Williams & Kurina, 2002).

The Lancet study (Santomauro et al., 2021) analyzed “204 countries and territories which revealed an additional case load of 76.2 million in major mental disorders and 53.2 million in anxiety disorders, out of which 35 million cases for major mental disorders and 52 anxiety disorders were of women in 2021.” Mental trauma and disorders are characterized and are predicted to have long-lasting impact

and destroy a women's autonomy and self-identity adding to her existing disempowerment (Kim et al., 2022).

Over the two waves of the pandemic, the rate of depression among women doubled in India not leaving behind the children who expressed their anxiety at different levels due to increasing social isolation and lockdowns. Studies have shown that the second wave further triggered mental disorders with widespread rates of infection. Standing at the forefront of the battle against the pandemic, women have been exposed to greater risk of infection and mental health disorders.

The National Commission for Women in India reported a surge of violence against women in the absence of "social and protective networks" (PFI, 2020). This is further exacerbated with early marriages, whereby projections of 31 million gender-based violence cases were projected during the lockdown (UNFPA, 2019). The impact of violence is lifelong be it physically or mentally. Not to forget the large number of frontline workers (especially women) who have been suffering hostile responses through the pandemic shows high levels of distress. In India alone, the ASHA workers (accredited social health activists) account for 1 million in the health workforce. They have been responsible for administering medical care in the remotest corners even during the period of lockdowns (MoHFW, 2020), not forgetting the role of Anganwadi workers (nutrition activists) and auxiliary nurse midwives who account for 17 million and 1.4 million, respectively, within the health force (*ibid*).

Rise in caregiving burden in India has affected 51% of adolescents in some of the biggest states of India, Uttar Pradesh, Rajasthan, and Bihar (*Ibid*, Pg 3). Social isolation, limited healthcare access, and stigma around mental health concerns have further burdened women and girls in seeking adequate attention toward their needs. Women from the informal sector have been hit the hardest in India due to loss of employment and livelihood. More than 60% of women in India form the informal sector, whereby loss of jobs affects their entire family and future (PFI, 2020). The poor and the most vulnerable sections of the country are suffering the most with long-term consequences in store for them.

Perceived Solutions in Sight

The health disaster in the form of Covid-19 has once again demonstrated that women and girls are inexplicably impacted in cases of conflicts, disasters, emergencies, and other fragile circumstances. The fundamental rights have been undermined whereby the long-fought goals are simultaneously knocked off. The Global Gender Gap Report 2021 has estimated that the "world has stepped back 39 years behind" as a result of Covid-19 that has exposed the inherent economic and social imbalances (Ghouaibi, 2021). The immediate need of the hour is to mainstream gender into disaster recovery processes. For resilient, efficient, and long-lasting recovery, policy building needs to adopt the gender lens for its strategy building. Women are exposed drastically to all kinds of disasters due to their existing vulnerabilities as determined by the structurally defined gender roles. "Gender plays an important role in assigning

roles and responsibilities within groups and in determining the access to and control of resources among groups, gender sensitivity and gender aspect become a valid and important policy domain during disasters and throughout the rehabilitation, recovery and reconstruction process" (IRP, 2007).

Engendered Recovery and Reconstruction in the Light of Covid-19: Recommendations

Covid-19 has once again drawn attention toward the urgency of incorporating a gender spectrum in relation to public health. Human development is largely characterized through public health indicators, whereby the marginalized sections need to be empowered principally. Integrating gender-appropriate mitigation strategies in the recovery phases will enhance and strengthen the resilience toward future disasters of any kind (*ibid*). The paper has tried to highlight the following recommendations in an attempt to "build back better" (IRP, 2007):

- The immediate normalization of essential reproductive and sexual healthcare services and ensuring its access to everyone at all times. UNFPA has reiterated the states to provide full access to prenatal and postnatal care and ensure regular supplies of birth control contraceptives and safe abortion care facilities at the earliest to avert any future morbidity (Beech, 2020). Revamping the primary health centers is a must for the village populations who have direct access to medical care in India.
- With drastic loss of jobs, families tend to neglect the importance of timely reproductive care. As a result, comprehensive health insurance coverage (Lindberg et al., 2020) is the need of the hour to restore regular access to care for mothers and children primarily. Furthermore, regular sources of investment are a must to ensure smooth supply of reproductive services irrespective of any disaster. Stakeholders must keep building international development schemes in the area of health to fight any form of health emergency as posed by Covid-19 (Genest et al., 2021).
- At the onset of the pandemic, one of the major blows was in the area of family planning measures. UNPF projected "7 million unintended pregnancies" in lower- and middle-income countries adding up to high maternal deaths as well, as seen in Nepal (Ghouaibi, 2021). Policy-makers need to build effective planning measures and generate investment for the same. The Population Foundation of India has predicted that "approximately 2.9 million infant deaths, 1.2 maternal lives and 206 million unsafe abortions can be forgone in the period of 2015–2031 in India" if quality family planning measures are adopted (PFI, 2020).
- Past disasters have depicted the need to adopt a gender analysis which is an imperative for justifiable recovery. Data is lacking in relation to gender-differentiated vulnerability in respect to disasters. WHO has called on its members to adopt "planning and actions for epidemiological research and surveillance to assess the immediate, medium and long term effects on sexual and reproductive

health” in the wake of the health disaster (Tang et al., 2020). The pandemic has highlighted the need to understand the gender implications aiming toward gender-responsive research.

- Lastly, voices of women need to be represented in the form of strong leaders within the national responses. Women have been underrepresented since the beginning despite standing at the frontlines of this disaster. This post-disaster recovery should see “women as leaders of recovery and develop capacities for social change” (UNDP, 2011).
-

Conclusion

The long process of disaster resilience needs to develop a strong relationship in terms of gender equality. Voices of both men and women need to be heard and their rights as similar as well. Policy-makers and stakeholders need to implement gender-inclusive strategy building in order to ensure the protection of fundamental rights of women in terms of disasters. Enhancing participatory and democratic voices will help in capacity building of women and resist stereotype biases. The goal to “build back better” seeks to turn adversity into “an opportunity for sustainable development, ‘seeking change in society’ in a more gender neutral manner” (IRP, 2007).

Annexure

- ASHA – accredited social health activists.
- DRR – disaster risk reduction.
- IPV – intimate partner violence.
- LMICs – low- and middle-income countries.
- MERS – Middle East respiratory syndrome.
- MMR – maternal mortality rate.
- OPD – outpatient department treatment.
- SARS – severe acute respiratory syndrome.
- SDGs – Sustainable Development Goals.
- UNDP – United Nations Development Programme.
- UNICEF – United Nations International Children’s Emergency Fund.
- UNPF – United Nations Population Fund.
- VHNDs – Village and Health Nutrition Days.
- WHO – World Health Organization.

Abstract

The Mt. Apo Natural Park (MANP) in Regions XI and XII in Mindanao, Philippines, is the Philippine's highest peak at 2954 MASL. It is a primary trekking and camping destination and an ASEAN Heritage Park. It is a legislated protected area classified as a natural park since 1936 via Presidential Proclamation No.59 and RA 9237 the Mt. Apo Act of 2003 and the ENIPAS Act RA 11038 of 2019.

It is governed by a multi-sectoral Protected Area Management Board (PAMB) with the Department of Environment and Natural Resources regional director as its chairperson and the Protected Area Management Offices of Regions XI and XII in Mindanao, Philippines, acting as its secretariat led by a protected area superintendent (PASu).

In the latter part of the twenty-first century, the MANP has faced two major disasters; these are the Mt. Apo Fire Incident of 2016 that decimated 116 hectares of brushland in its strict protection zone (SPZ) near the peak and a landslide that has affected a major transportation artery and several local communities in 2019.

This study aims to measure the level of disaster preparedness of the governing Protected Area Management Board with the descriptive analysis of its current policies such as the MANP General Management Plan (2013–2023) and the

F. R. Buenaflor (✉)

disaster preparedness plans of selected local governments as mandated by RA 10121 (Disaster Preparedness Act of 2009) and RA 9729 (Climate Change Act of 2009) and the Ancestral Domain Sustainable Development Plan (ADSDPP) of the unified Bagobo-Tagabawa Tribe in MANP. The study will outline recommendations with the purpose of formulating strategies for the enactment of improved board policies leading to improved disaster planning, management, and recovery for the Mt. Apo Natural Park.

Mt. Apo Natural Park is an ASEAN heritage site, an active stratovolcano, and the highest peak in the Republic of the Philippines at 2954 MASL.

Mt. Apo Natural Park · Disaster preparedness · Disaster planning · Protected area management

Introduction

The Mount Apo Natural Park in the Davao Region is a primary trekking and mountaineering destination in the Philippines and in the ASEAN Region by being the highest peak in the Republic of the Philippines and because of the varied mountain ecosystems that it can offer its visitors (DENR, CARCAP, 2018). The natural park's draw to nature enthusiasts has reached its pinnacle in the 2016 peak season where more than 500 guests were camping at the peak area in the Lenten season on March 26. An uncontrolled butane stove fire spread and decimated 116 hectares of brushland in the peak area. No loss of life occurred, but resources utilized by the national and local governments to halt the spread of the brushfire were

costly, and this has resulted in a Bureau of Fire “fire out” declaration in May of the same year.

This fire incident has resulted in the crafting of policies by the Protected Area Management Board (PAMB) of Mt. Apo Natural Park whose ex officio members comprise the 2 governors, 7 mayors, 44 barangay captains, leaders of indigenous cultural communities (ICCs), and the various national government agencies with a stake and mandate in the Mt. Apo Natural Park (MANP).

These policy issuances were in the full implementation of PAMB resolution 2015-01, “The unified trekking policy for the MANP” and “The Camp Management Policy for the MANP.”

The umbrella policies that govern these PAMB issuances are the primary guidelines that cover the management of the park including its disaster preparedness. These are the (I) General Management Plan 2013–2023, (II) Ancestral Domain Sustainable Development Plan, and the (III) Comprehensive Development Plans of the local government unit.

The MANP-GMP 2013–2023

General Management Plan of the Mt. Apo Natural Park is the enhanced plan for the Mount Apo Natural Park that covers a 20-year period, beginning in 2013. The elements of this GMP include (a) shared vision and mission; (b) unified goals, objectives, and conservation outcomes; (c) integrated management programs and strategies; (d) institutional arrangement and management; (e) unified management zoning; and (f) management standards and guidelines.

The vision and mission of this GMP reflect the desired condition of MANP in the future and are further translated into specific goals and objectives, which are similarly the consolidation of the different goals and objectives of the numerous plans covering the PA and its buffer zones. Goals are broad statements on what this plan wants to achieve in the next 10 years and further scaled down into specific objectives. These goals and objectives are aimed at responding to management issues and concerns affecting the protected area and its buffer zones.

There are six major management programs presented in this management plan. Each management program is further divided into several components with corresponding outputs, specific strategies, and activities. The main purposes of the different program components are presented in detail so that stakeholders shall be guided in implementing this GMP. The management programs included in this GMP are as follows: (a) Biodiversity Research, Protection and Rehabilitation Program; (b) Indigenous People’s Affairs and Cultural Program; (c) Community-Based Resource Management Program; (d) Participatory and Community-Based Ecotourism Program; (e) Institutional Strengthening, Partnership, and Co-management Program; and (f) Disaster Risk Reduction Management and Climate Change Adaptation Program.

For the Disaster Risk Reduction Management and Climate Change Adaptation Program, this was added in the later enhancement stage of GMP preparation. This

program is necessary because of the emerging changes in the climatic patterns affecting Mindanao where Mt. Apo is located. There is a need to build the resiliency of the PA ecosystems to extreme weather disturbances to ensure sustainable development and biodiversity conservation. This was also added to answer the need to identify the potential sources for sustaining the implementation of this plan which prompted the inclusion of the topic. The DRRM/CCA concerns were also incorporated considering that the health of the MANP upland natural ecosystems constitutes a potential source of hazards for the downstream settlements. The impacts of climate change on the Mount Apo Natural Park General Management Plan 2013–2033 and on the economy, biodiversity, and the safety of the settlements downstream are subjects that were also discussed in the plan (MANP-GMP, 2013).

Thus, the primary motivation for the later inclusion of the disaster risk reduction and climate change facet of the plan was added primarily for the purpose of leveraging possible internal or external funding of the plan, the health of the MANP ecosystems affecting the lowland inhabitants, and building the resiliency of ecosystems in the protected area.

The UBT ADSDPP 2019–2023

The unified Bagobo-Tagabawa Tribe's Ancestral Domain Sustainable Development and Protection Plan for 2019–2023 for its Certificate of Ancestral Domain Title/Claim covers nearly 90% of the Mt. Apo Natural Park (MANP-GMP, 2013). It outlines the required demographic, ethnographic, geographic, political, and social structures of the largest indigenous cultural community within the Mt. Apo Natural Park. In this plan the IP/AD (indigenous people's/ancestral domain) Development Framework, the major issues outlined cover the environment, socioeconomic-agricultural, and basic needs. The environment sector covers the issues of declining biodiversity, soil and land pollution, haphazard farming and settlement in SPZ (strict protection zone) of MANP, and environmental degradation.

The primary goal of this plan is to create a healthy and productive environment that is able to sustain biodiversity and generate nondestructive economic progress for the benefit of the indigenous peoples and all other entities in Mount Apo. The development goals are anchored in the four bundles of rights of the indigenous cultural communities/indigenous peoples (ICCs/IPs), the right to ancestral domains/ancestral lands, right to self-governance and empowerment, social justice and human rights, and right to cultural integrity and the responsibilities of the ICCs/IPs to their ancestral domain as stipulated in Section 9 of IPRA for sustainable development and protection of the ancestral domain. These responsibilities are the following: (a) maintain ecological balance, to preserve, restore, and maintain a balanced ecology in the ancestral domain by protecting the flora and fauna, watershed areas, and other resources; (b) restore denuded areas, to actively initiate, undertake, and participate in the reforestation of denuded areas and other developmental programs and projects subject to just and reasonable remunerations; and (c) observe laws, to observe and comply with the provisions of RA 8371 and the rules and regulations for its effective implementation.

This plan does not outline any issues or strategies that cover disaster risk reduction and management except for the identification of the need to hire forest guards, increase law enforcement, and conduct of information education campaigns and reforestation programs in landslide-prone areas. The plan prioritizes basic needs and services which are an apparent immediate need.

The Davao Regional Development Plan 2017–2022

The Davao Regional Development Plan 2017–2022 outlines the development roadmap on how the Davao Region in the Philippines can achieve the Philippine Development Plan 2017–2022. These are anchored in the national vision of (1) building a prosperous, predominantly middle-class society where no one is poor; (2) toward promoting a long and healthy life, implementing the 2016–2022 Philippine Health Agenda; (3) toward becoming smarter and more innovative, reviewing higher education institution curricula toward matching industry requirements; and (4) toward building a high-trust society, improving access to basic social services. The plan outlines environmental challenges and recognizes that climate change and water scarcity will pose serious threats to countries in South and Southeast Asia over the next several decades. These threats, which range from extreme weather events to limited water availability, are likely to have significant impacts on the Philippines' economy and its sectors. The challenge for Davao Region is on ensuring the environment and natural resources' sustainability for the present and future generations, while achieving economic growth and development (DRDP, 2017). The plan also recognizes Davao Region's vulnerability to hazards that are hydrometeorological and geologic in nature, namely, flooding, rain-induced landslides, and active fault lines, and has prioritized research agendas for this aspect (DRDP, 2017). The plan has also validated that all 53 LGUs have been validated to have functional Local Disaster Risk Reduction and Management Councils (LDRRMCs), established Local Disaster Risk Reduction and Management Offices, and installed early warning systems in the event of upcoming disasters. A “massive” orientation and training on DRRMCCA especially in vulnerable communities shall be undertaken. Coordination among government agencies such as the Department of Agriculture (DA), Bureau of Fisheries and Aquatic Resources (BFAR), and Department of Environment and Natural Resources (DENR), among other agencies, shall also be pursued to ensure the protection and preservation of the environment and natural resources (DRDP, 2017).

The focus of the paper is twofold:

1. The paper aims to present a descriptive analysis of the level of disaster preparedness in terms of MANP policies (such as RA 9237, RA 10121, RA 9729, and RA 8371 and specifically their realization in the MANP General Management Plan 2013–2023, the ADSDPP of the unified Bagobo-Tagabawa Tribe, and the related PAMB policies) and the Davao Regional Development Plan 2017–2022.

2. It also aims to determine policy recommendations for the improvement of DRRM disaster risk reduction and management in MANP.

The study utilized a simple descriptive narrative research study (Glass & Hopkins, 1984) where it involved data gathering that describes events and then organizes, tabulates, depicts, and describes the data collection (Glass & Hopkins, 1984). With the interim volume of information from the plans covering Mt. Apo Natural Park and the limited time frame and resources for the study, the topics from the three plans were reduced in manageable form, gleaning from the main sources the topics and points that covered disaster risk reduction and management. These points were outlined based on the similar statements that covered disaster risk reduction and how it is planned to be implemented in the aforementioned plans. The researcher also utilized similarities in the plans in relation to (1) aspects covered, (2) time frame, (3) DRMM aspect/s, (4) budget allocated, (5) specific programs, and (6) harmonization and cohesion between these three key plans.

Disaster risk reduction in the context of key plans that cover the Mt. Apo Natural Park

Aspects covered	MANP-GMP 2013–2023	Ancestral Domain Sustainable Development and Protection Plan 2019–2023	The Davao Regional Development Plan 2017–2022
Time frame	10 years	5 years	6 years
DRMM aspect	Goal 7 disaster risk reduction management and climate change adaptation program	The plan focused on the immediate needs of the unified Bagobo-Tagabawa tribe	Environmental challenges and recognizes climate change and water scarcity and Davao Region's vulnerability to hazards that are hydrometeorological and geologic in nature
Budget allocated	To be determined	To be determined	To be determined
Specific programs	States that IEC, patrols, and reforestation efforts need to be in place for mitigation measures	Outlines the need for coordination with the mines and geosciences bureau of the DENR for determination of hazard areas within their domain	Outline research avenues and possible strategies for adaptation and mitigation
Harmonization and cohesion	Several aspects of the GMP are similar in goals to the ADSDPP and can be complementary to the ADSDPP and the DRDP	The ADSDPP is also similar to the GMP and DRDP and is complementary to both plans but there are differences in timelines	Acts as the overall plan that is supposed to be the mother plan for the two previous plans and is also research supportive since it outlines the research initiatives needed

Conclusions and Recommendations

The three plans assessed in the study have stated the need for disaster risk reduction, management, and preparedness. It is apparent that there is a cursory mentioned of the negative impacts of climate change, but there is still a lack of awareness on the need to instill the need for awareness, planning, and action. The LGUs in the DRDP 2017–2023 all have functional Disaster Risk Reduction and Management Councils, DRMM Offices, and quick-response teams. However, there is a lack of coordination among the three plans for harmonization, coordination, and sustainable planning. This is apparent with the different time frames of the three plans, and these plans from the top-down should be collaborative and unified in nature.

1. Increase collaboration, communication, and cooperation among ICC, PAMB, and NEDA stakeholders in the formulation of unified plans.
 2. Timely synchronization of plans from the top-down DRDP to GMP and ADSDPP with an enabling law that will mandate this strategic action.
 3. Further studies on the level of disaster risk reduction and management for the Mt. Apo Natural Park.

Abstract

The government has always played a role in disaster governance, including at the community level. The Indonesian government has also allocated responsibilities to the local governments in disaster governance mechanisms. The aim of this study is to explore the regulatory and institutional framework for disaster governance, which emphasizes arrangements between city government organizations and communities to address disaster vulnerability. This research was conducted in coastal cities of Indonesia that are prone to disasters: Bandar Lampung, Semarang, and Makassar. The research method used is regulatory mapping (RegMAP), conducting discourse network analysis (DNA) and risk-based analysis based on threats, vulnerabilities, and capacities. The results of the study found that the framework for enforcing disaster governance rules in Indonesia is often contradictory, including the main issues in determining disaster status, budget allocation and regional cooperation, as well as strengthening the capacity of vulnerable communities. The regulatory framework needs to be reviewed to reduce the risk of flood disasters that often occur in the cities of Makassar, Semarang, and Bandar Lampung; the disaster management agency and development planning board are the front line to internalizing the disaster risk reduction agenda; and the need for

Resilient cities · Vulnerable communities · Coastal · Disaster governance

Introduction

After political reforms in 1998, Indonesia has launched extensive decentralization in political, administrative, and financial affairs. These changes, which brought reforms to the governance system with extensive political and economic impacts (Prianto, 2013, 2017a, b; Das & Luthfi, 2017). Decentralization gives the local governments the powers to manage and control their own affairs (Prianto, 2012). Indonesia is a country that is vulnerable to disaster (Djalante et al., 2017; World Bank, 2019). The last decade has seen how Indonesia suffers from major disasters that have a great impact (Das & Luthfi, 2017).

The Indonesian National Disaster Mitigation Board (BNPB, 2021) reported that between January and December of 2021, a total of 3058 natural disasters struck Indonesia. The majority of natural disasters were hydrometeorological. There were 1288 occurrences of flooding, 791 occurrences of extreme weather, 623 occurrences of landslides, 265 events of forest and land fires, 44 occurrences of tidal waves and abrasion, 31 occurrences of earthquakes, 15 occurrences of droughts, and 1 occurrence of a volcanic eruption. Java Island experienced a total of 1559 disasters.

Disasters and unexpected impacts are very dangerous and cause complex problems (Singh, 2018). The human population increase and the impact of climate change have caused the vulnerability and threat of disasters to become increasingly complex, frequent, and full of uncertainty. Disaster management also needs to change and adapt to institutional values. Facing the threat of disaster necessitates the need for a paradigm shift, from government to governance, by further expanding the roles and interactions of inter-institutional arrangements (Peters, 2019). Governmental regimes chosen from democratic procedures are expected to anticipate various public problems, which cannot be solved by only one single organization (Huxham et al., 2000). To this day, the terms “coordination,” “synergy,” “partnership,” “collaboration,” and “network” are an important part of public sector governance activities (Prianto et al., 2022).

There is a great deal of common terminology associated with efforts to prevent and respond to disasters, including disaster risk reduction (DRR) and disaster management (DM). DRR focuses on reducing disaster risk through systematic efforts to analyze and manage the causative factors, such as by reducing hazards and reducing the vulnerability of people with assets, wisely trying to manage the environment, and enhancing the level of readiness for adverse events (UNISDR,

2011; Mardiah et al., 2017). This reflects a growing understanding that DM entails more than responding to emergencies, and that preventative action in day-to-day planning and governance is crucial (Miller & Douglass, 2016).

From a mainstream perspective, the concept of DM implies several physical preventive measures, such as evacuation, reactive response during and after a disaster; with emergency aid, humanitarian assistance, and reconstruction (Singh, 2018). The new DM framework and decentralization have increased the role and responsibility of local governments in regional disaster response actions. But the frameworks do not work congruently, thus resulting in new challenges. As an example, DM effectiveness is based on local government capacity (especially adequate human resources and budget allocation); however, the capacities depend on pre-existing political and socio-cultural dynamics, where they have been changed by the impact of political decentralization, which varies widely (Antlöv et al., 2016; Bebbington et al., 2006). The increase in the authority and responsibility of local governments has not been matched by adequate capacity (Faisah & Prianto, 2015; Prianto et al., 2021; Rusnaedy et al., 2021). Therefore, it is very important to explore highly decentralized Indonesia, managing the new DM framework and its achievements and possibilities in the future.

What are the most significant effects of decentralization on disaster administration? How does the new framework for DM in Indonesia affect local governments' roles, responsibilities, and capacities? These are the primary questions that this chapter will address. Therefore, the objectives are as follows: (1) identify how decentralization affects local governance in Indonesia; (2) investigate how the new DRR framework will affect the roles, responsibilities, and capacities of local governments; and (3) discuss the effect of decentralized governance structures on enhancing community resilience to DRR frameworks.

The research method used is the Regulatory Mapping (RegMAP) method, a method for reviewing institutional arrangements through Discourse Network Analysis (DNA) and risk analysis based on threats, vulnerabilities, and capacities. Institutional networks describe cause-and-effect relationships among disaster events, institutional responses, and community actions; explore the roles of stakeholders in the government and community sectors, as well as adaptation actions taken to deal with disasters; studying economic, political, and cultural aspects under certain adaptation conditions. This study uses qualitative research techniques: reviewing the relevant official literature (reports, regulations, articles, and books); document analysis; content analysis and interviews; media news to supplement field information about DM and DRR initiatives.

This approach explores risk based on threats, vulnerabilities, and capacities. Trends in the impact of climate change or weather describe a cause-and-effect relationship between a disaster and certain aspects of the community, such as disaster literacy, decreased income, and gender sensitivity. Data were analyzed and interpreted through the steps data reduction, data presentation, data verification, to conclusions, which produce new findings.

Critical Factors of Disaster Governance in Indonesia

Geographical characteristics of urban areas in Indonesia, classify them as areas that are vulnerable to disaster threats. Disasters can cause several bad consequences for cities and their communities, the potential for hydrometeorological disasters, such as floods, landslides, forest fires and droughts. Rapid growth and increased urban activity increased the threat of damage to the urban environment. Urban areas are increasingly vulnerable to hydrometeorological disasters (floods, landslides, and droughts) that occur alternately in many areas in Indonesia (Amri et al., 2016). This article focuses on several coastal cities in Indonesia, the consideration of the choice is that these coastal cities have a medium and high disaster risk. The situation in Indonesia, where almost all coastal cities, have a moderate and high level of disaster risk. We identified problems in three coastal cities, namely Bandar Lampung city, Semarang city, and Makassar city. This choice is based on the level of disaster risk at the cities.

Based on Fig. 1, the level of disaster risk in coastal cities is in the high and medium categories, with a high hydro-meteorological disaster threat scale. These cities have improved to become cities that are resilient and adaptive to disasters. Actions promote resilience, through capacity building at the local government level, regulation making, and budgeting support. Nevertheless, disasters still hit periodically. Table 1 identifies problems in the three selected coastal cities, namely the city

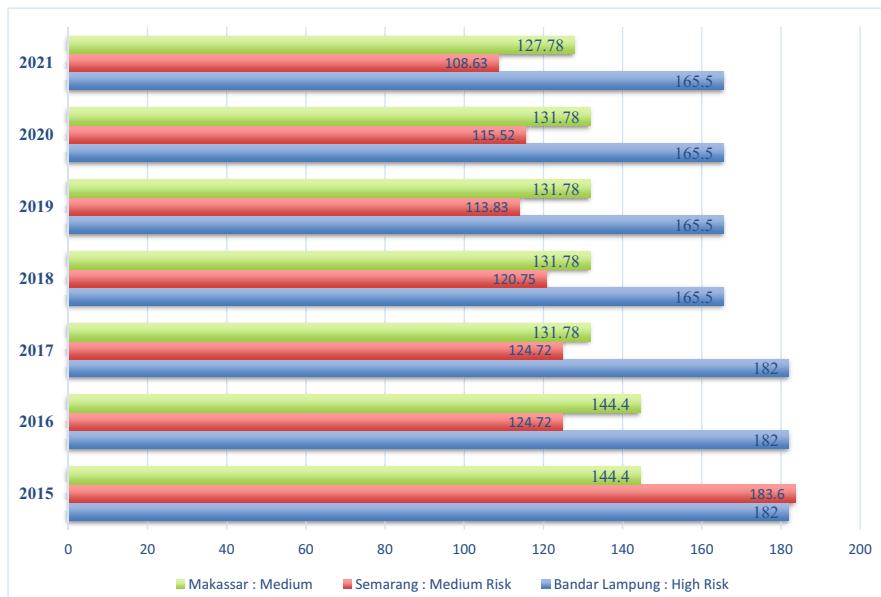

Fig. 1 Disaster Risk Index in Indonesian coastal cities 2015–2021. Source: InaRisk, Indonesian National Disaster Mitigation Board – BNPB (2021)

Table 1 Identification of disaster problems

No.	Cities	List of Disaster Issues
1	Bandar Lampung	The impact of disaster problems that occurred in Bandar Lampung City was caused, among others, by: Urban design and governance and Community activities in watershed boundaries People are still littering. Weak enforcement of legal sanctions
2	Semarang	Disaster problems in the city of Semarang are caused by High tide flood Unsustainable management of the mangrove ecosystem Topographic conditions are in the coastal areas, lowlands, and highlands
3	Makassar	Disaster problems in Makassar City are: Vulnerability of women in coastal areas The Lorong Garden program from the Makassar City Government actually adds to the burden for women Urban development is neither environmental friendly nor participatory Low adaptive capacity to climate change impacts

Sources: Sihotang (2020), Intan (2019), Erlani & Nugrahandika (2019), Danarto et al. (2019), Kurnianingsih & Santosa (2019), Chandra (2017), Malik et al. (2021), Rusnaedy et al. (2021), Prianto et al. (2021), Razak (2021), Fajar Pendidikan (2021)

of Bandar Lampung, the city of Semarang, and the city of Makassar. Based on this table:

Based on Table 1, the main problem is the flood disaster in the three cities. In Bandar Lampung City it is caused by city governance and urban design that are not realized, then there are still people littering, violating watershed boundaries set by the government, and enforcement of regulations is not optimal; it does not have a deterrent effect on violators. The coastal disaster of Semarang City is due to the area's topography, unsustainable management of mangrove ecosystems, and tidal flooding. Then, the causes of coastal disasters in Makassar city are unfriendly and have less participative development, as well as the threat of climate change impacts on women in coastal areas. Another finding is that the Lorong Garden Program by the Makassar City Government actually adds to the burden on women and the weak adaptation capacity to the threat of climate change.

Increased urbanization in Indonesia's fast-growing cities has brought burdens and vulnerabilities, especially for the urban poor communities. Even the municipal government services are not able to serve the residents who continue to come to the city, who have ultimately been marginalized for years and increasingly forgotten in times of crisis. Decentralization becomes two-faceted: to provide opportunities as well as threats in urban services. The policy authority allows city managers to solve the problems of city residents, but at the same time, implementation and frameworks that are not optimal to bring progress to the city. In order for cities to meet current and future challenges, national governments must complete a decentralization agenda that holds local governments fully accountable. At the same time, the dynamics of cities must accommodate local people's aspirations by improving

urban services, reducing poverty, and promoting local economic development (Asia, 2003).

Mitigating Climate Change Impacts in Coastal Cities

Disaster risk reduction is an approach to disaster management through mitigation and preparedness. The disaster management strategy in three coastal cities in Indonesia, namely the city of Bandar Lampung, the city of Semarang, and the city of Makassar, can be seen in Table 2:

Based on Table 2, the disaster management strategy in three coastal cities in Indonesia is explained as follows. In Bandar Lampung city, the procedures for dealing with it include expanding education areas and green areas; as a water catchment area, then normalize, naturalize, and build drainage to drain water; from upstream to downstream. This technical activity is supported by the collaborative action of various groups such as academics, environmental organizations, and local leaders in finding solutions, such as education and literacy activities to the community on disaster mitigation, by conducting disaster-resilient community training.

In the city of Semarang, the disaster management strategy began by integrating city activities with global movements, namely the 100 Resilient Cities program; to encourage the Semarang City Government to be more resilient in dealing with the threat of shock and stress. This action is supported by mangrove ecosystem management policies with community-based disaster risk reduction policies and

Table 2 Disaster governance strategy in coastal cities in Indonesia

No.	Cities	List of disaster governance strategies
1	Bandar Lampung	The strategy of the Bandar Lampung city in disaster governance is: expanding green areas that function as water catchment areas: Carry out normalization, naturalization, and build irrigation drainage Encourage collective and collaborative action in disaster management Promote education and literacy as disaster mitigation
2	Semarang	The disaster governance strategy in Semarang City is: 100 Resilient Cities program to build resilience in dealing with shocks and stresses Reduce vulnerability through the integration of mangrove ecosystem management and disaster risk reduction policies Design of disaster information system based on geospatial technology Standard Operating Procedure (SOP) for disaster management, from pre-disaster mitigation to post-disaster reconstruction
3	Makassar	The disaster governance strategy in Makassar City is Increasing the percentage of public green open space Improving the quality of infrastructure and public services Improving socioeconomic welfare, which is gender sensitive Strengthening the adaptive capacity of city governments Strengthening the resilience of coastal women

Sources: Sihotang (2020), Intan (2019), Erlani & Nugrahandika (2019), Danarto et al. (2019), Kurnianingsih & Santosa (2019), Chandra (2017), Razak (2021), Fajar Pendidikan (2021), Malik et al. (2021), Rusnaedy et al. (2021)

community empowerment to reduce vulnerability. Another program is the design of a geospatial-based disaster information system to make it easier for the public and stakeholders to obtain disaster information and to develop operational standards for disaster management, from mitigation to post-disaster reconstruction.

In the city of Makassar, the government programs such as the preparation of action plans for DRR, increasing the area of green open space, improving the quality of infrastructure and public disaster services, and increasing gender-sensitivity on social welfare policy. Another step is to strengthen the adaptive capacity of local governments in mitigating the impacts of climate change, as well as increasing the resilience of coastal women. Based on the disaster management strategy, the three cities were built, all based on the government, where the government builds city resilience with the support of regulations, budgets, and government employees. Meanwhile, the strategy developed at the community level is not yet connected to the strategy developed by the government. In these three cities, the city government's resilience strategy has not been able to deal with vulnerability at the community level.

Disaster Risk Reduction: Capacity, Decentralization, and Collaboration

Collective and collaborative action have had an impact on increasing resilience in disaster risk reduction in Indonesian urban areas (Singh, 2020; Malik et al., 2021; Rusnaedy et al., 2021). Organizing coastal women's communities is an effort to strengthen vulnerable entities in urban communities. They are involved in collaborative DRR actions. The reality of the vulnerabilities faced include damage to living space, decreased income, and limited clean water services, which further adds to the socioeconomic burden of coastal women.

Decentralization is the transmission of political, financial, and administrative authority to local government in an effort for them to provide superior public services. Numerous factors contribute to the effectiveness of a decentralized system, including: (1) institutions and human resources implementing the plan; (2) facilities, technology, information accessibility, budget, and institutional support; (3) infrastructure, technology, and information accessibility; and (4) institutional support (Prianto, 2012). In a decentralized system, the bureaucratic relationship between all areas of government is very complex, thereby increasing the complexity of provincial and global environmental policies (Steurer & Clar, 2015). In a decentralized system (federal system), the ruling political party has a strong influence, frequently limiting environmental political initiatives that conflict with do-nothing policies (Rabe, 2011).

Climate change policy research in Austria reports that a decentralized system for climate change governance is becoming increasingly difficult, because bureaucratic relationships between all levels of government in a decentralized (federal) system are very complicated, which in turn slows down climate change responses at regional and national levels. For example, in Austria's construction policy, the Ministry of national environment faced opposition from two other ministers and nine provincial

leaders. Owing to opposition from the federal government, construction policies often clash in the middle of the road (Steurer & Clar, 2015). The Austrian Environment Minister also finds it difficult to implement his climate change agenda because the responsibility for implementing the policy lies with other ministries.

Under the administration of George Bush, Jr., Barack Obama, and Donald Trump, US climate change policy went through critical times. Donald Trump decided to close the US Environmental Protection Agency, which ultimately exacerbated the crisis (Koski & Siulagi, 2016). The Republican Party is the largest political party and has always opposed climate change policies on the grounds that it would harm American industry. The Democrats are not Republicans, but their important figures such as Barack Obama and Hillary Clinton cannot promote the issue of climate change in their party.

According to the study, obstacles can be overcome through coordination and a shared vision between the federal and local governments. Government, private, and community institutions must collaborate to achieve socioeconomic benefits through sustainable programs (Chienwattanasook & Prianto, 2018; Jermitsittiparsert et al., 2019a, b; Sriyakul et al., 2019; Sutduean et al., 2019). Municipal governments reduce their vulnerability to climate change by influencing the community's sensitivity and adaptability. This can be achieved through physical and nonphysical actions (including capacity building, enhancing government service administration, supporting the local community organizations, and enhancing networks) (Malik et al., 2021; Rusnaedy et al., 2021).

The discourse and practice of building urban resilience is more frequently centered on the government. The government has the privilege of encouraging resilience, with regulations, budgets, and apparatus resources that control the territory. Community-based actions in building resilience have not received the attention of various parties. In fact, in three coastal cities; Bandar Lampung, Semarang, and Makassar; resilience challenges at the community level are still being faced.

In Table 3 it is explained that the resilience of the community in Bandar Lampung City, Semarang City, and Makassar City mean that they have their own approach to facing the risk of disaster impacts, as in the Kampung Bumi Mas Bandar Lampung program as a disaster-resilient village. In Semarang City, the settlement strategy of the Tambak Lorok fishing community faced tidal flooding. Furthermore, in Makassar City, disaster-resilient communities are represented by Anging Mammiri Women's Solidarity Organization and Muhammadiyah Disaster Management Center (MDMC) in flood disaster management in Makassar City. MDMC, through disaster mitigation actions, builds more literacy and disaster preparedness education. Meanwhile, the Anging Mammiri Women's Solidarity Institution has transformed into an institution that advocates for disaster-resilient communities, especially for coastal women who are very vulnerable to risk of disasters. At the level of policy advocacy at the city government, the programs that are being encouraged include (1) gender-based public policy, (2) improvement of socioeconomic welfare, and (3) increasing public green open spaces.

It is hoped that these coastal cities will execute the right strategy. The analysis concludes that decentralization and disaster management are often different. The fuzziness of capacity and collaboration of civil society has not supported DRR.

Table 3 Community resilience in dealing disasters in Indonesian cities

No.	Cities	List of community resilience
1	Bandar Lampung	Kampung Bumi Mas Bandar Lampung as legal-based disaster-resilient village and community development: Increasing basic legal knowledge about disaster-resilient villages Institutionalizing community participation Strengthening the function of law as a means of social control Concern for every stakeholders
2	Semarang	Tambak Lorok coastal settlement Household level adaptation Filling the land and increasing house building as an adaptation to tidal flooding Developing a vertical fishing village
3	Makassar	Disaster-resilient community in Makassar City: Muhammadiyah Disaster Management Center using a mitigation approach through disaster education and literacy Anging Mammiri Women's Solidarity As a resilient community facing disaster risks, it focuses on (1) gender-sensitive policies, especially for coastal women; (2) improvement of socio-economic welfare; (3) improvement of public Green Open Spaces

Sources: Mussadun et al. (2016), Evendia (2021), Fajar Pendidikan (2021).

Critical issues that arise include local institutional capacity and weak coordination and collaboration with communities.

Conclusion

In this chapter, we conclude that the resilience of cities to disaster vulnerability in coastal areas of cities in Indonesia finds that (1) the framework for enforcing disaster management rules in Indonesia is often contradictory, especially on the main issues in determining disaster status, budget policy, and regional cooperation, as well as strengthening the capacity of vulnerable communities. The regulatory framework needs to be reviewed to reduce the risk of flood disasters that often occur in the cities of Makassar, Semarang, and Bandar Lampung; (2) City government institutions, such as the Disaster Management Agency and the Development Planning Agency, are at the forefront of internalizing the DRR agenda; and (3) the need for strategic policies in DRR that are integrated, climate inclusive, and have the adaptive capacity to address vulnerabilities at the community level.

Abstract

The vulnerability of settlements to the risk of abrasion disasters is caused by the phenomenon of changes in the land area of the coastal area of Barrang Lombo Island, Makassar, as a result of the pattern of settlement toward the waters and the decreased vegetation of coastal ecosystems. This research looked at how vulnerable residents of Barrang Lombo Island were to the risk of abrasion from the island's social, economic, and physical aspects. Vulnerability risk classification research methodologies, map overlay techniques, and interviews with vulnerable groups are all used in this study. Using risk analysis based on threats, vulnerabilities, and capabilities, the data is then created. The findings demonstrated that the high vulnerability of the physical aspect of the residential environment was caused by a number of factors, such as: (1) residential buildings with typologies above the waters located on the western side of the island with a frequency of disasters almost every year experiencing the risk of abrasion disasters; (2) wave-

Architecture, Universitas Muhammadiyah Makassar, Makassar, Indonesia

e-mail: annisa@unismuh.ac.id

holding embankment infrastructure was only built on the east side; and (3) the density of residential buildings, especially above the waters. From an economic standpoint, vulnerability is the shift in the primary cycle of the people who work as fishers to other forms of subsistence employment. The density of population and the number of vulnerable groups with disabilities, particularly traditional diver fishermen, are linked to social vulnerability. The vulnerability to abrasion risk ranges from a high-risk level of 5.77 to a moderate level of 1.23.

Vulnerability of settlements · Abrasion disasters · Residential building · Economic vulnerability

Introduction

Indonesia is an archipelagic country that experiences the impact of global warming and sea level rise which will affect the vulnerability of Makassar as a small-island urban area in the form of a mainland and an archipelago subdistrict. Of 15 areas, there are eight subdistricts that are directly adjacent to the coastal areas of the Makassar Strait with a coastline of 35 kilometers consisting of 11 small islands which are part of Sangkarrang Archipelago Subdistrict. Mining activities in the coastal area will raise the possibility of disaster in the coastal areas of Makassar due to increasing sea stockpiles or reclamation. The habitat of mangrove plants will be eliminated and this would result in more erosion and abrasion (Zulkifli Aspan, 2017).

The degraded environmental carrying capacity in the Makassar coastal area is caused by a lack of control over space utilization and the geomorphological conditions of the coastal area that is prone to disaster risk and with an estimated 5–10 mm/year sea level rise in the Makassar Strait (Timang et al., 2013). Meanwhile, the quality of the aquatic environment is very influential on the survival of coastal communities and small islands, because most of the people's livelihoods depend on marine products. Around 70% of the population depend on fishing activities. Others work as construction workers in the city, small traders, civil servants, and fiber boat craftsmen and even work in water transportation services or shops selling fishery products (Tamti et al., 2014). Based on the Tejakusuma Research of a geological review of the Makassar coastal area, sand, gravel, coral limestone, and mud clay are classified as very vulnerable with an elevation of 0–5 meters indicating that the vulnerability is very high (Tejakusuma, 2020). In addition, changes in the coastline of Makassar City indicate erosion and accretion where the southern coastal area is dominated by accretion while in the northern part is dominated by erosion. While abrasion is the erosion of coastal areas due to sea waves, the severity of abrasion to coastal areas also depends on the balance in the area. Expanding coastal areas can become a factor for an accelerated ongoing impact such as land flooding on small islands, beach erosion, sea water intrusion, and ecological changes in coastal

areas because the more a region is vulnerable, the easier it is to cause damage or change (Tahir et al., 2009).

Tahir et al. (2009) describe the vulnerability of sea level rise index in medium vulnerability based on three vulnerability parameters (elevation, population density, and population growth) with the score in Barrang Lombo Makassar Island with an index of 8.33; this island is predicted to have a large threat from sea level rise as an inundation area as in 2100 up to 80% more than its landmass. Almost every year Barrang Lombo Island experiences a change in coastline due to abrasion. Another phenomenon, based on interviews with local communities, was that before the abrasion disaster, the coastline was still visible, but now most of the island has no beaches, especially the western part, and the buildings that surround the island are not only on the mainland but shifted toward sea. The majority of the population of Barrang Lombo Island depend on the sea for their livelihood, where the main livelihood of the population is fishing. The category of fishermen on Barrang Lombo Island is based on the size of the boat and the type of catch. Fishermen who use large boats are sea cucumber fishermen. Fishermen using medium-sized boats are squid fishermen, while fishermen using small boats are fish fishermen, who are more often called papekang. There are around 88 sea cucumber fishermen who use large boats to go to sea. Fishermen who use it include fishers, squid fishermen, and papekang fishermen. Due to these economic factors, on average, those who work as fishermen choose to live close to the beach so that it is easier to monitor the boats and access to transportation from the boat moorings to their homes and where the catch is drying is easier and closer. Due to the dense population and the pressing need for housing, many residents choose to live on the coast which has entered the coastal border area. This is also the main factor that makes residents carry out reclamation independently, which has become a habit for those whose houses are directly adjacent to the beach to stockpile the sea without considering the safety, security, and comfort aspects of living.

Communities who choose to live bordering the Barrang Lombo beach border assume that the area directly adjacent to their land parcel is their territory, so they strive to be able to take advantage of it by expanding or adding space from the previous dwelling (Heriansyah, 2016). The results of the initial survey showed that another issue that caused the reclamation was one of the Barrang Lombo community's efforts to deal with coastal abrasion by levying the back of the parcel which is a marine area for reasons of security and safety from disasters. Meanwhile, when the abrasion occurred, the houses that were most affected were those located on the coastal border and above the sea and spatially located in the western part of Barrang Lombo Island. The adaptations being carried out in Barrang Lombo at this time are to build embankments on their parcel boundaries, elevate the house buildings, and build parts under the houses on stilts. In this study, it is very urgent to identify the impact of abrasion on the Barrang Lombo residential area, especially fishermen's residences, and assess the risk of abrasion disasters that occur and identify types of adaptation to the residential environment both from the aspect of residential buildings and environmental infrastructure. The negative impact of abrasion requires the people of Barrang Lombo Island to make a choice whether

they will stay in the disaster-prone settlements so that there needs to be interventions and efforts to handle these settlements. When a community chooses a place to live, a possible scenario is needed for community resilience and vulnerability reduction. This type of adaptation strategy is very important to be formulated with the aim of reducing the impact of disaster risk caused by abrasion.

Previous studies have studied more about the impact of erosion and flooding on coastal settlements, the vulnerability of coastal settlements due to climate change, and the direction of structuring coastal settlements based on erosion mitigation. Research in Makassar City related to disasters is more about coastal mitigation zoning and the risks of floods, fires, and landslides at Losari Beach Makassar. Meanwhile, research on Barrang Lombo itself that has been carried out concerns more about social and disease aspects and the vulnerability index of Barrang Lombo Island which has been carried out for a long time. Coastal settlements tend to have characteristics of high vulnerability and low capacity to disasters. This research is more focused on vulnerability analysis to determine the level or category of abrasion vulnerability of Barrang Lombo Island. The results of the vulnerability analysis are expected to contribute value that is useful in handling and mitigating disasters for coastal communities and specifically for local fishing communities living in Barrang Lombo Island. The contribution of this research to the development of science is to provide benefits for the development of urban settlement design studies and city theories that need to be considered in urban development. This research can enrich knowledge in the field of urban coastal settlement architecture, especially disaster vulnerability in fishermen's housing and help guide detailed spatial plans or zoning of coastal areas and small islands, especially in the context of capacity building for future island disaster mitigation.

The other side is to add research results that are oriented toward scientific collaboration in solving problems or challenges of coastal development. In contrast to previous studies, which were more dominant in studying economic and social aspects, the formulation of the adaptation strategy of fishermen's dwellings against the risk of abrasion disaster can be a reference for Makassar City government's consideration in formulating a sustainable direction of planning and coastal management in the long term, especially in the Spermonde archipelago. In addition, this research can develop an approach that is more oriented to the characteristics of buildings and local communities. Based on the above, it is considered important to conduct research with the formulation of the following problems: (1) How is the physical vulnerability, economic vulnerability, and social vulnerability of abrasion disasters in the coastal settlements of Barrang Lombo Island, Makassar City? (2) How is the level of vulnerability to abrasion disaster risk on Barrang Island? Lombo?

Disaster Vulnerability

Vulnerability can be measured based on exposure, sensitivity, and capacity by systematically integrating social and environmental aspects to reduce the frequency of risk and intensity of disasters (Chakraborty & Joshi, 2016). The importance of

assessing economic, social, and infrastructure vulnerability as an effort to develop effective mitigation strategies shows that increasing population and worker ratios are marginal and locations are selected based on density level and number of assets at risk (Sherly et al., 2015). Vulnerable households dealing with disaster events are temporarily moving, and 7.4% of the affected buildings are neglected and abandoned; from this study it was also found that access for urban residents is better than rural residents in obtaining post-disaster assistance packages (Wahab & Falola, 2022). Meanwhile, the results of the study (Lome-Hurtado et al., 2021) on urban households in Mexico which explored the relationship between morbidity and physical disability in vulnerable age groups, both children and parents due to exposure to natural events, showed an increasing impact of 52.8% for the elderly and 13.6% for children. Global environmental changes and pressures also affect community resilience in the face of natural disasters (Pelling & Uitto, 2001). Pre-disaster vulnerability and post-disaster recovery from the spatial aspect are influenced by development, sociocultural processes, perceptions of risk, attitudes, and beliefs both directly and indirectly (Thompson & Dezzani, 2021). The vulnerability index based on the components of economic impact, distribution, and sector size (Yu et al., 2014) found that the private service sector has a high vulnerability, followed by the trade, real estate, and residential ownership sectors. The poor are the most vulnerable group because they struggle more than other community groups for security and livelihood sustainability to cope with or recover from disasters (Le De et al., 2015). Disaster risk reduction planning has the potential to create new vulnerabilities such as the case of resettlement (Kita, 2017); however these efforts do not solve the main causes of vulnerability in disaster-prone areas such as construction security, poor infrastructure systems, institutional capacity, and land and settlement locations. Remote communities in island locations tend to experience a crisis of trust and do not want to rely on external parties, so it can be said that capacity and vulnerability coexist within a population (Hamza et al., 2021). The model of disaster management in Thailand was explored by Busapathumrong (2013) which focuses on vulnerable groups of women, children, and the elderly as well as people with disabilities in disaster-affected communities.

Disaster Risk

The frequency of disasters that experienced a fluctuating increase over a 13-year period in Zhuhai, Zhongsan, Dongguan, Jiangmen, and Shenzhen based on research conducted by Wang et al. (2022) was caused by a decrease in the area of vegetation cover and an increase in population, gross domestic product, and built-up area. Communities living in mountainous areas have low capacity to face natural disaster risks due to their spatial locality (Baig et al., 2021). Disaster management system applied in a city in terms of integrity and priority emphasis on disaster risk reduction efforts, participation, and collaboration as and community coordination. However, potential disaster risk can be analyzed using a tiered method to classify causes, effects, and escalation points both on the potential scale and level of damage caused

by disasters (Shakeri et al., 2021). Prediction of flood risk assessment using the method of combining Bayesian network models and Geographic Information Systems (GIS) has been applied in research (Shakeri et al., 2021), and after applying this method to diagnose the cause of flooding, the results are then compared with actual conditions.

The data used to measure the level of vulnerability to disaster risk are primary data and secondary data. Primary data consists of the results of field observations and mapping and the results of risk assessments based on Focus Group Discussions with the community regarding the conditions and history of disasters and identification of disaster risk factors from the aspect of threat sources and capacities. While secondary data comes from the publications of the Central Statistics Agency (BPS) of Makassar City, RTRW, Zoning Plan for Coastal and Archipelago Regions, and BPBD (Regional Disaster Management Agency) of Makassar City. To obtain accurate secondary data and primary data, the authors use data collection techniques through literature studies, field observations, analysis of disaster risk studies, spatial mapping, and vulnerability level overlays. The overlay method is a map merging system that unites spatial data sourced from different layers and generates attribute data in a hierarchical manner (Darmawan et al., 2017). Data analysis techniques used are the following: (1) overlay method (map overlapping) which looks at shoreline changes, using data from Google Earth per 5 years of land use development and shoreline changes, (2) and abrasion disaster risk assessment analysis which is obtained using the formula:

$$\text{Risk} = \frac{\text{threat} \times \text{vulnerability}}{\text{capacity}}$$

Disaster risk is seen as a multiple function by Wisner et al. (1994) that formulated three key elements to identify abrasion risk, namely risk, vulnerability, and hazard with an equation model: $R = H \times V$. Furthermore, it is said that the root of vulnerability is a social process, so analytical models related to human vulnerability and exposure to physical hazards due to natural events are used. A threat is an event that has the potential to cause injury, loss of life, or loss of property. This threat can be catastrophic or not. A threat is considered a disaster if it has caused casualties and losses. Examples of threats are fires, landslides, earthquakes, droughts, and floods. Vulnerability is a condition of a community or society that leads or causes inability to deal with the threat of disaster. Capacity is the combination of all existing resources in a community that can reduce the level of risk or impact of a disaster.

Results and Discussion

Land Use Change

Barrang Lombo Island is a coral island from the flat island group, with an area of about 20.58 ha. Barrang Lombo Island is one of the small islands in the administrative area of Ujung Tanah District, Makassar City. This island is poor in vegetation,

where about 90% of the island's land surface has been used as a residential area, and the only empty spaces remaining are sports fields, roads, and yards. The beaches around Barrang Lombo Island are dominated by sandy beaches, only a small part of which are rocky or pebble beaches with a total length of 2809.11 m. Most of the beaches have been constructed of concrete coastal protection structures that also function as security for buildings or houses for residents, especially on the west, east, and north sides with a length of about 2188.92 m. Barrang Lombo Island is a flat island with a maximum height of 200 cm above sea level with a fairly high density level, while the settlement pattern in the Barrang Lombo Islands is circular settlements. This island is also a concentration of public services for other islands in the Spermonde island group in the waters of Makassar City. Barrang Lombo Island is an island that stretches southwest of Sulawesi. Based on the policy overview of the Makassar City Spatial Plan for 2015–2034, the spatial pattern plan for Barrang Lombo Island is as follows: (1) protected areas including conservation areas for coastal areas and small islands and Spermonde waters; (2) areas prone to natural disasters such as tidal waves or sea level rise, coastal abrasion, and sedimentation disasters; (3) medium density residential area; (4) natural tourism area; (5) disaster evacuation room area; and (6) allotment area for capture fisheries in the coastal zone. One of the indirect causes of abrasion is land use change. The increasing pressure on land conversion where the beach on Barrang Lombo Island is shrinking from year to year due to conversion to residential buildings, so that the coastal zone of Barrang Lombo Island is almost completely covered by buildings. The development of the population from year to year as well as various community activities and began to penetrate into trade and services (Table 1).

Based on the results of interviews with residents of Barrang Lombo Island, mangroves still grow on the coast, but as the community activities to park boats and want to get closer to their homes, mangrove trees are cut down because they are considered to be blocking the circulation path of water transportation. Previously on this island there were still areas of mangrove vegetation on the coast. However, over time the increasing activity of fishing communities as well as the need for parking spaces and boat moorings made people to start cutting down mangroves. Due to the perception of the island community, especially those who live in outer areas, the

existence of these mangroves hinders the circulation of their boats when they are going to land. Initially, this island was known for its clear waters and the abundance of a variety of fish and other marine animals. However, now the shoreline has become shallow that the bottom can be seen because it is only 1 m deep. Meanwhile, the water depth at the pier is only about 3 m. The increasing area of this island is due to large-scale reclamation by the population in the last 10 years (Fig. 1).

These phenomena are also in line with the result of Veron et al. (2019) study that island is considered as the most vulnerable against climate change, there is expected change in temperature, rainfall, and/or sea level, islands are at risk due to climate change found in all latitudes, for example in Australia, Indonesia, Antarctica, Pacific islands, the United States, and more especially near the equator. Assessing vulnerability of each island is the first step toward risk analysis to identify where climate change is most. One of the factors causing the reduction is inorganic waste that accumulates on the coast. This will certainly have an impact on ecosystem damage

and reduce the ecological role and potential of an ecosystem, including seagrass ecosystems, and have implications for the role of seagrass as a habitat, a place to find food for various organisms where this condition occurs on the south, west, and north sides of the island (Shakeri et al., 2021).

Residential Building: Physical Vulnerability

Physical vulnerability of residential buildings in the condition of residential buildings. Most of them are unfit for habitation. In addition, people who are in the outermost layer of the island live outside the shoreline due to the impact of abrasion with the erosion of land areas. Coastal reclamation is independently carried out by residents as an adaptation of buildings to sea level rise, beach abrasion, and sedimentation disasters. The types of buildings consist of stilt houses with wooden construction, semipermanent houses, and landed houses. There are still many semi-permanent houses that use wood materials, such that when extreme weather often occurs it causes damage to the residence.

Residential Infrastructure Vulnerabilities

Reduced water catchment areas and vegetation density due to the increasing proportion of pavement with paving block surfaces or concrete rebates, violations of the basic building coefficient rules and coastal demarcation lines, and settlements on the edge and above the sea. This results in suboptimal infiltration and the potential for sea level rise every year which increases with high rainfall. Nearly 70% of roads on Barrang Lombo Island do not have drainage. This is based on the public perception that the character of the sandy soil is easy to absorb water, so drainage is not needed. There are 492 meters of existing drainage, but the condition is not maintained and so it smells and causes slums. Some residents who live on the beach need their own drainage as a channel for disposing of their household waste into the sea (gray water waste).

In general, the disaster on Barrang Lombo Island greatly affects vulnerability to water and sanitation conditions. This is because the quality of the infrastructure changes when there is a change in weather, the rainy season and the disaster of sea level rise, abrasion and coastal sedimentation. Based on field observations, it is known that the residents' clean water sources are obtained from dug wells and reservoir piping networks. There are 16 dug wells with brackish water conditions during the dry season, while in the rainy season the conditions are generally fresh. There is 1 unit of public well which is in fresh condition because there is still a lot of vegetation around the well location, including breadfruit. This is also a standard for local communities to identify the presence of water sources. There are nine Reverse Osmosis (RO) drinking water depots that serve drinking water needs with a selling price of Rp. 3500 to Rp. 5000 which are managed by 1 unit of community

institutions and the other by community businesses. Apart from drinking water, sanitation conditions are also vulnerable to disasters. Households on the beach do not have a septic tank and so their wastewater is directly discharged into the sea; the residents' septic tank is adjacent to a well; communal wastewater treatment plants (WWTPs) are available but they have not been able to meet the needs of all residents and are constrained by the cost of maintaining the WWTPs, and gray water waste stagnates on the streets and yards, thereby polluting the environment. From the aspect of the availability of waste management, the location of the islands requires a local and independent waste management system. Because the service system is not integrated into the city system, the location accessibility to the city center is separated by sea waters. The results of identification in the field, there are 4 units of garbage motors transporting residents' waste to a local final processing site (TPA). The TPA's waste processing is still traditional, involving burning, which causes pollution and residue.

Economic Vulnerability Due to Abrasion

In general, the coastal economy of Barrang Lombo Island is very dependent on fishermen because it is the dominant sector and is the main livelihood of the community (82%). So when fishermen's income is disturbed due to seasonal factors (dry and rainy seasons) as well as due to the risk of abrasion, it will automatically have an impact on the decline in other livelihood incomes. In addition to the impact on livelihoods, economic vulnerability from the risk of abrasion is also on assets and income. The vulnerability of the Barrang Lombo community to abrasion disasters has an impact on damaged residential assets where people with high income are able to build embankments and repair their dwellings (low vulnerability). On the other hand, people with low income are less adaptable to disasters (high vulnerability). Spatially, it can be seen in the following vulnerability map (Fig. 2).

Abrasian Disaster Risk Analysis Study

Abrasian disaster risk analysis study is based on the results of interviews with the community from the historical aspects of disasters that have occurred, namely, abrasion, cyclones, fires, tidal waves, and tsunami predictions. The shrinkage of the coastal area is the most obvious impact of coastal abrasion. The waves of ocean currents that usually help the fishermen's departure and return routes or provide a beautiful view and atmosphere on the beach then become terrible. The hard blows on the coast can vibrate rocks and soil which will slowly separate from the land area and become part of the flooded area. This also directly threatens the survival of residents around the coast who have houses or business spaces, such as in the coastal area of Barrang Lombo, where reclamation is carried out by the community; of course they

Fig. 2 The results of the mapping of economic assets of the Barrang Lombo Island livelihood. (Source: Author's Analysis (2022))

feel the impact directly, and they need prevention so that the impact does not expand (Fig. 3).

Abrasion disasters occur almost every year; natural factors that can cause abrasion include ebb and flow of seawater, wind over the ocean, ocean waves, and destructive ocean currents. Of course, the natural factors that cause this abrasion cannot be avoided because the sea has its own cycle (Table 2). Abrasion threats are assessed based on indicators of the occurrence of waves/tides and storms/strong winds as follows:

Abrasion vulnerability study is based on indicators of social vulnerability, economic vulnerability, and physical vulnerability. (1) Social vulnerability looks at the level of population density and the presence of vulnerable groups (elderly, children, and people with disabilities). (2) Economic vulnerability looks at the level of the

Table 6 Capacity value

Number	Capacity type	Rated capacity (1/2/3)	Notes
1	Institution	2	The population density is quite moderate in the slum delineation location; it is very risky to cause fatalities when abrasion occurs
2	Beach embankment	1	The coastal embankments are only on the north, east, and south sides, while on the west side there is no embankment so it is very vulnerable Against abrasion
3	Mangrove vegetation	1	There has never been a mangrove planting around the island of Barrang Lombo

economy and sources of livelihood. (3) Physical vulnerability looks at the level of building density, the distance between buildings, and building construction (Tables 3 and 4).

Capacity to deal with abrasion is based on organizational indicators, distance of public and social facilities, and presence of coastal embankments and mangrove vegetation (Tables 5, 6 and 7).

Conclusion

Based on the results of the abrasion disaster risk assessment, the level of abrasion disaster risk is in the high and medium categories. There are seven RTs (Veron et al., 2019) that have a high risk of abrasion, namely, RT 001 RW 001, RT 002 RW 001, RT 003 RW 001, RT 001 RW 002, RT 002 RW 003, RT 002 RW 004, RT 004 RW 004, and RT 005 RW 004. Areas at high risk of abrasion are mostly located in the western part of the island due to the influence of sea waves and westerly winds, and mostly there is no coastal embankment in the western part of Barrang Lombo Island. Based on the result of identification in the field, vulnerability analysis, identified sources of threats, vulnerabilities, and capacities that directly affect the risk of abrasion caused. Sources of threats based on successive events are high waves, high tides, and strong winds. Based on observations and studies,

Table 7 The results of the overlay of threat, vulnerability, and capacity studies as described in the abrasion disaster risk map

Sumber ancaman abrasi berdasarkan kejadian:

1. high wave
2. tide water
3. strong winds

vulnerability to abrasion risk is caused by high population density, high building density, vulnerable groups, history of abrasion occurring every year, position of the coast to the west wind direction, and distance from the coast. Meanwhile, the capacity value is low because the coastal embankment is only installed on the east side of the island, there is no mangrove vegetation, and the disaster response agency is less active.

Based on the study in this chapter we conclude that vulnerability to abrasion disaster risk on Barrang Lombo Island is triggered by physical vulnerability where there is a decrease in the quality of basic infrastructure, especially clean water and sanitation due to seawater intrusion during abrasion. Abrasion causes a reduction in the land area of the island so that community housing increases toward the water. This condition affects social vulnerability, namely the high number of children at risk of stunting due to inadequate clean water and sanitation, which has implications for increasing the number of vulnerable groups. Meanwhile, economic vulnerability occurs successively in the dry season, rainy season, sea level rise, tidal flooding, which is then followed by abrasion, which greatly affects the mobility of fishermen in going to sea. So when the source of income of fishermen as the dominant sector on the island is disrupted, it automatically affects the side income of the community in other informal businesses. Thus, the sea is still the main source of livelihood for urban island coastal communities so that abrasion as one of the natural disasters that occurs causes risks of vulnerability for the community in terms of environmental, social, and economic.

Abstract

Land lies at the fulcrum of protecting and sustaining the lives, livelihood, and well-being of millions of species and communities. Land is also a central vent of all forms of disasters. Land management in its most pristine existence is critical for disaster preparedness, for mitigation, and for reducing the economic losses caused due to disasters. Through this chapter, an attempt is made to study the interlinks between land use and the growing intensification of disasters. It also highlights how unabated use and exploitation of land reduces the coping capacity of land and makes it even more vulnerable to disaster risks. The interrelationship between land and disaster is thoroughly examined to find out the factors responsible for decline in the productive usage of land and its underlying impact and intensification of disasters that has incurred as a result of unsustainable land management practices. The study underlines how sustainable land-use management practices through protection of the natural habitats can severely reduce the risk and vulnerability and contribute to DRR.

Disaster · Land management · Ecosystem · Development · Disaster risk reduction (DRR)

Introduction

The need for judicious land management is critical for disaster preparedness, for mitigation, and for reducing the economic losses caused due to disasters. Land is a synthesis of different ecosystems, namely, rivers, wetlands, forests, wastelands, drylands, and coastal areas whose prudent use and planning is extremely important to achieve the objectives of disaster risk reduction (DRR). Over the past several decades and centuries, land is exposed to various vagaries of natural and man-made changes that have caused metamorphic changes in land use. Man-made changes have been particularly extrapolated due to various underlying concerns of urbanization, unplanned development, deforestation, and population explosion. The increase in human population is estimated to escalate to 9.8 billion people by 2050 and 11.2 billion by 2100 (IPCC, 2019) that will result in more urbanization, infrastructure buildup, and demand for food, and this would ultimately entail drastic shifts in land management. The escalated pressures on land in the form of land-use changes ultimately result in deforestation, land degradation, coastal erosion, soil erosion, and loss of productivity, thus triggering loss of pristine ecosystem functions and contributing to disaster risk. The key concern is therefore to manage the underlying pressures on land in a sustainable manner that takes into consideration the risks associated with its unbridled and escalated use.

The annual accumulated value of the world's total terrestrial ecosystem services has been estimated as approx. 75 trillion USD in 2011, which is equivalent to the annual global gross domestic product (GDP) of 2007 (IPCC, 2019). There are various global frameworks that have identified land use as a key factor for disaster risk management (Shaw & Banba, 2017), for instance, the Hyogo Framework for Action (HFA, 2005–2015), Sendai Framework for Disaster Risk Reduction (SFDRR, 2015–2030), and Sustainable Development Goals (SDG, 2015–2030). HFA (2005–2015) was the first global framework to rationalize DRR efforts that set forth five priorities for action, namely, institutionalize DRR efforts at both national and local levels; identify, assess, and monitor disaster risks; reduce underlying risk factors; and strengthen disaster preparedness for effective response. Among the priorities listed in HFA, land-use planning is one of the dominant factors to be adopted to reduce disaster risk and vulnerabilities. The global agenda for DRR was further strengthened in the SFDRR that entails four priorities focusing upon understanding disaster risk, strengthening disaster risk governance to manage disaster risks, investing in DRR for resilience, and enhancing disaster preparedness for effective response and to build back better. Land-use management has been the focus of SFDRR in its priorities of action that builds upon mainstreaming disaster risk assessments into land-use policy formulation and implementation. In comparison to

the HFA, the Sendai Framework targeted more on the factors responsible for escalation of disaster risk, of which land management in terms of land-use planning plays a critical role. Sustainable land-use management has been identified as a critical factor to achieve SDGs' targets. Goal 15 of SDG agenda aims to "protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss." The recent "Sustainable Development Report" (2021) provides an overview on the performance of the member countries and has ranked India at 120 out of the total number of 165 countries with a cumulative score of 60.1. India is ranked much below to some of the countries in the South Asian region like Bhutan (70), Sri Lanka (68.1), Nepal (66.5), and Bangladesh (63.5). According to the Sustainable Development Report (2021: 56), sustainable land use has been identified as one of the pivotal societal transformations that is imperative to achieve the SDG goals. It is thus important to have a holistic approach toward sustainable land-use management policies and practices.

While significant efforts have been made by the international and national governments in terms of early warning systems (EWS) and disaster response, the systematic failure of the national governments to strengthen disaster risk governance in terms of growing population, urbanization, and unsustainable land-use management practices has been of great concern. These factors are responsible for increasing the risk and hazards that ultimately enhance our vulnerability to disasters.

Land (Mis)Management and Land Lost

Land lies at the fulcrum of providing a safe and secure habitat to millions of species and native communities whose livelihood depends on land, but at the same time, there are underlying anthropogenic pressures on land for robust development and economic growth that cause inimical threat to growing intensification of disasters. The conundrum between land as a habitat and its unbridled exploitation makes it critical to adopt sustainable land management practices. Land management entails a process of fair and equitable management and utilization of land resources. Land entails a synthesis of different ecosystems whose sustainable planning and use is critical to reduce disaster risks and contribute to DRR. However, escalated pressures on land over centuries in terms of putting pressures on land for agriculture, grazing, urbanization, and economic development have indeed reduced the coping capacity of land to deal with the pressures of climate change and disaster risk. This has indeed caused land degradation, desertification, deforestation, and coastal erosion that have resulted in intensification of disasters in terms of drought, floods, forest fires, etc. This has in fact posed an enormous loss to the ecosystem and is a threat to humanity. Land is thus being lost to the growing intensification of disasters in the form of floods, landslides, and droughts. This section will discuss how substantial pressures on land in terms of land degradation, desertification, coastal erosion, and urbanization have reduced the productivity of land and its pristine nature and made it more vulnerable and fragile to deal with disaster risks.

Loss of Land Due to Land Degradation and Desertification

Land degradation results in loss of ecosystem and is significantly caused due to anthropogenic pressures, unsustainable agricultural practices, land fragmentation, urbanization, population growth, and climate change. It has been estimated by the Desertification and Land Degradation Atlas of India (2021) that out of the total land area of 328.72 million hectares in India, 97.85 million hectares is undergoing land degradation which is 29.77% of the total geographic area (TGA) during 2018–2019. The level and intensity of land degradation witnessed by the country have increased exponentially to 96.40 million hectares (29.32 percent of TGA) and 94.53 million hectares (28.76 percent of TGA) in 2011–2013 and 2003–2005, respectively. There are various factors such as soil erosion, salinity, alkalinity, acidity, mass movement, frost shattering, and waterlogging that cause land degradation, and among them the most significant cause for land degradation has been water erosion which is 11.01 percent followed by vegetable degradation at 9.15 percent and wind erosion at 5.46 percent in the year 2018 and 2019, respectively (Desertification and Land Degradation Atlas of India, 2021). Soil erosion is also a big concern as about 1 millimeter of top soil is lost every year due to erosion, thus causing land degradation (State of India Agriculture Report, 2017: 129).

Desertification, i.e., land degradation within the dryland regions, has also been a major cause of concern, and it is estimated by the report on desertification (2021) that about 83.69 million hectares of land has undergone desertification during 2018–2019. This has also intensified in the recent years from 82.64 million hectares and 81.48 million hectares in 2011–2013 and 2005, respectively. In arid regions, the most significant cause for desertification has been wind erosion, while in semiarid and dry subhumid regions, it has been water erosion and vegetation degradation that are of utmost concern. The report also highlights that more than 50 percent of the land area in the five states of India, i.e., Jharkhand, Rajasthan, Delhi, Gujarat, and Goa, is undergoing desertification and land degradation.

Land Lost Due to Coastal Erosion

The physiography of India includes a long coastline of 7516.6 km that stretches along Arabian Sea in the west and Bay of Bengal in the east. The long coastline comprises nine states which includes 5422.6 km of mainland coastline and 2094 km of island territories. The shoreline along the coast is subject to continuous change due to natural causes such as action of waves, winds, tides, nearshore currents, storms, sea level rise, etc. and is nevertheless exacerbated by anthropogenic factors such as urbanization, development activities, beach sand mining, and destruction of mangroves. This results in depletion of the coastline which results in significant land loss that causes destruction of the ecosystem and natural habitat and poses a great challenge for impending coastal disasters. The National Centre for Coastal Research (NCCR) in its report submitted to the Ministry of Earth Sciences (July 2018) has stated that between 1990 and 2016, 336.52 km of

shoreline (34 percent of cost) has faced erosion. Among the states, West Bengal in the east coast has faced the maximum loss in terms of coastal erosion that accounts for 336.52 km (63 percent), followed by Pondicherry, Kerala, and Tamil Nadu that accounts for a total loss of 23.80 km (57 percent), 263.04 km (45 percent), and 407.05 km (41 percent), respectively. Coastal erosion has also a profound effect in terms of land loss, and this is manifested from the fact that between 1990 and 2016, approx. 231.50 sq. km of land has been lost due to erosion along the coasts. Maximum damage has been accrued to the state of West Bengal that has witnessed a total land loss of 99.05 sq. km. The extent of land loss has been so immense in West Bengal that the NCCR report (2018) reveals that Chumkur island that once covered an area of 133 hectares has been eroded. Similar trends of erosion are also being witnessed in the case of Jumbudweep, Henry, Ghoramara, and Mousini islands of West Bengal region. The eastern part of India that is known for its majestic biodiversity and culture is also experiencing unprecedented loss, e.g., Majuli, which is the largest mid-Atlantic deltaic islands in the world. It has witnessed a massive contraction as it has shrunk from its original size of 1256 sq. km to 515 sq. km.

Urbanization and Informal Tenure

Urbanization is also a driving factor that increases pressures on land and leads to unparalleled expansion of cities and urban agglomeration. This leads to formidable augmentation of cities, development, and infrastructure projects tearing apart the natural habitat and ecosystems that are crucial for disaster preparedness and mitigation. It leads to spatial fragmentation of hinterland to serve the needs of growing urban population and economic growth. According to Pandey et al. (2018), the impact of urban land-use change has been nonlinear, i.e., following multiple changes over time, and it results in devastating consequences over the biosphere through land use, habitat loss, and changes in biogeochemical cycling, climate, and hydrology. As per the Census of India (2011) estimates, India's urban population stands at 31.16 percent of the total population, and the percentage of population living in urban areas has witnessed an upsurge of over 3.35 percent over 2001 estimates (27.81 percent). Among the big metropolitan cities, NCT of Delhi (97.50 percent) and Chandigarh (97.25 percent) are the most urban populated cities (Census of India 2011). Rise in urban population has also led to tremendous increase in the number of cities and towns that has increased from 5161 in 2011 to 7935 in 2011. Rise in urbanization leads to insurmountable challenges for the ecosystem as its upsurge leads to trespassing the natural and safe habitat areas that surround the periphery of urban areas. According to Patra and Kantariya (2014), disaster risk in urban settings is primarily driven by urbanization. The natural habitats in the form of forests, wetlands, mangroves, and lakes act as a buffer to protect the cities from the disaster risks. UN-Habitat in its "World's Cities Report" (2020) has alarmed that less developed regions of East Asia, South Asia, and Africa with three countries – India, China, and Nigeria – are more prone to the growing intensity of urbanization

and will together account for 35 percent of the total rise in global urban population from 2018 to 2050.

Increase in trends in rural-urban migration also results in urbanization, and this results in rise of urban agglomerations in the form of informal tenure settlements and slums. The 2001 census recorded that 43 million (23 percent) population of India's urban population were living in slums, and this statistics increased to 93 million in the 2011 census (Patel, 2017). The World Bank estimates that in 2018, 35.2 percent of the urban population were living in slums. Overcrowding, lack of adequate space and basic facilities, poor sanitation, and informal tenure with dilapidated living conditions and surroundings escalate their disaster risks. Their exposure to unsustainable living conditions disproportionately impacts them and makes them even more vulnerable. For instance, Dharavi, one of the world's largest slum in Mumbai, has a population density of 270,000 people per square kilometer.

Land Mismanagement and Its Vulnerability to Disasters

Land in its most pristine form has been exploited to generate capital out of it in the form of changing its land-use, building infrastructure, factories, industries, unsustainable agricultural practices, markets, and real estate business. This development-led euphoria has bereft the natural habitats out of its ability to sustain its ecosystem functions and protect it from natural hazards or risks. The natural resource base of land that exists in the form of forests, mangroves, wetlands, aquifers, and water channels has been destroyed, and this has been a major underlying cause for the growing intensification of disasters. The natural habitats act as a natural carbon sink which is critical for disaster preparedness and for mitigating risk. As per UNDRR report (2020), between 2000 and 2019, India has witnessed an exponential rise in the number of disasters with 321 catastrophes that makes it the third largest disaster-affected country worldwide after China (577) and the United States (467). The cumulative loss of people affected by disasters between 2000 and 2019 has also been to a great extent witnessed by India (1083 m) and China (1729 m), respectively, that together accounts for 70 percent of the total population affected worldwide.

A major cause for the growing intensification of disasters in the last two decades owes much to the land mismanagement practices that have destroyed the natural habitat areas that once existed to protect the area from disasters. There are numerous instances of land mismanagement that have resulted in the destruction of natural ecosystem and habitats and that have been the major underlying cause for the proliferation of disasters. This ranges from the destruction of mangroves in the Sundarbans region and destruction of ecological fragile zone in the Western Ghats to loss of green cover and water bodies in the major urban cities of India. A thorough examination of these instances has been explicitly discussed in this section to demonstrate the interlinkages between land misuse and proliferation of disasters.

The Sundarbans mangroves which is one of the largest mangrove forest (140,000 ha) that lies on the delta of Ganges, Brahmaputra, and Meghna on the

eastern side of Bay of Bengal has been destroyed and exploited for unnatural use. The ecologically fragile region of Sundarbans that lies on the side of India and Bangladesh has lost 24.55 percent of mangroves, i.e., 136.77 square km of land due to erosion between 1984 and 2018 (Bhargava et al., 2021). A major reason for the loss of land has been due to the conversion of Sundarbans mangroves for paddy cultivation and shrimp farming (Ghosh et al., 2015). Increase in shrimp farming has destroyed the natural habitat of Sundarbans mangroves and made it prone to increased levels of salinity. Increased salinity has the potential to destroy the ecosystem of mangroves which is critical to maintain the sustainability of the region. Mangroves are critical to protect the coastal ecosystem and to mitigate the impact of natural hazards as they act as a safeguard against strong winds, cyclones, tsunamis, and storms. Chakaria Sundarbans that lies in the district of Chittagong region, Bangladesh, in the delta of Matamori River with a recorded area of 71 square miles in 1911 has been completely destroyed due to the rapid expansion of shrimp farming and increased levels of salinity in the region. The destruction of the Chakaria Sundarbans can have similar ramifications in the adjoining Indian side of Sundarbans. There have been land management laws that protect the natural habitat of the region from land-use conversion, for instance, the West Bengal Land Reforms Act (1955) (S. 4D) that explicitly puts any conversion or alteration in land as a cognizable and nonbailable offence; the West Bengal Inland Fisheries (Amendment) Act (1993) (S.17 A) that bars conversion of water area for other use, and the Coastal Aquaculture Authority Act (2005) that prohibits coastal aquaculture in the coastal regulation zone (CRZ) (S. 13 (a, b)). In *S. Jagannath vs Union of India (1996)*, the detrimental impact of the rising shrimp industry on coastal environment and marine ecology was acknowledged. The judgment constituted an authority to protect ecologically fragile region of the coast and implement the precautionary principle and polluter pays principle. It also prohibited shrimp farming within the coastal regulation zone as defined by CRZ notification of 2011. However, the enforcement of these laws has been bleak to give way for rich global prawn industry to set its business in the Sundarbans. This has significantly contributed to increased levels of salinity, deforestation, and loss of biodiversity. The destruction of mangroves has paved the susceptibility of the region to floods and sea level rise, thus resulting in coastal land being lost. Out of the 102 islands in the Sundarbans region, only 54 are inhabited. Ghoramara Island which once comprised of a total area of 26 sq. km has shrunk to just 6.7 square km due to coastal erosion. The once inhabited Ghoramara Island with a population of 40,000 has shrunk to just 5193 as per the 2011 census.

Similar land mismanagement practices in the ecologically fragile zone of Western Ghats are resulting as a backlash in the form of insurmountable disasters in the region. One such instance was the unprecedented Kerala floods of 2018 that swept the incredible “God’s own country.” The unprecedented Kerala floods were the result of lack of preparedness at the institutional level, failure of political leadership to protect the ecosystem, and neglect of local self-governments and communities. The ecological sensitivity of the region was realized much earlier by the “Western Ghats Ecology Expert Panel” (WGEEP, 2011) report that declared that the entire Western Ghats region as an ecologically sensitive area (ESZ). This was the first

groundbreaking report that highlighted the ecological sensitivity of the region that was swept away by the unprecedented change in land use and was leading the region to the vulnerability of impending disasters. Most of the recommendations given in the Gadgil report were dumped aside as it sparked a debate between development and protecting the ecosystem and natural habitat. Singh (2016: 70) had already stated that “any wavering on implementing the CRZ law will make areas closer to water bodies vulnerable to disasters amounting to huge socio-economic destruction and loss of lives.” Kerala is a state with a mosaic of ecosystems that includes forests, mangroves, freshwater lakes, and marine ecosystem which is abode to a variety of rare, endemic, and endangered species of plants, birds, and animals. The rich ecosystem of Kerala is reeling under gigantic anthropogenic pressure in the garb of GDP-centric exclusionary growth that is sweeping off its pristine natural ecosystem that exists in the form of forests, wetlands, and mangroves, and this is resulting in impending disasters in the region. Mangroves have shrunk from 700 km² in 1975 to just 9 km² in 2021 as per the Forest Survey of India (FSI) statistics. There are just three districts in Kerala that include Ernakulam, Kannur, and Kasaragod with moderate and open forest mangrove cover. In terms of agricultural land use, there has been a tremendous reduction in the land utilized for paddy cultivation. This has been replaced by switching over to growing cash crops or utilizing land for developing real estate. The area under paddy cultivation has lowered down drastically from 8.8 lakh hectares in 1970–1971 to 3.2 lakh hectares in 2001–2002 and finally succumbing down to 1.98 lakh hectares in 2019–2020 (Agricultural statistics 2019–2020, Government of Kerala). Interestingly, among the plantation crops (tea, coffee, rubber, and cocoa), the share of rubber plantation is 80.2 percent, and the land utilized for rubber plantation has increased from 4.75 lakh hectares in 2001–2002 to 5.51 hectares in 2019–2020. This has had serious ramifications for the environment and ecosystem as conversion of paddy fields and wetlands impacts groundwater recharge and increases the severity of floods and erosion. Interestingly, the Kerala Conservation of Paddy and Wetland Act that was introduced in 2008 to stop the conversion of wetlands has been amended in 2018 to allow reclamation or conversion of wetlands justifying that this will not adversely affect the cultivation of paddy and free flow of water thereto.

Cities and urban areas are reeling under pressure of excessive heat and are turning into heat chambers. There has been an increase in the mean maximum temperature due to loss of green cover and trees which used to once provide a safety net against rising temperature. Increasing urbanization is resulting in outward expansion of cities and growth of built-up areas. This is indeed resulting in more concretization of land by destroying the green cover and natural habitats of the cities that used to once exist in the forms of lakes, wetlands, water bodies, and city forests. As per India State of Forest Report (ISFR 2021), the top mega urban cities where green cover has drastically reduced are Ahmedabad (from 17.96 sq. km in 2011 to 9.41 in 2021), Bangalore (from 94 sq. km in 2011 to 89.02 sq. km), and Kolkata (from 2.52 sq. km in 2011 to 1.77 sq. km in 2021). These are also cities that are turning into heat islands, and it is expected that the temperature of 70 percent of land surface in Ahmedabad will rise up to 45 degrees Celsius by 2025. Another reason for the rise of

heat temperatures is also due to the loss of water bodies that have the potential to mitigate the heating effect.

Similarly, Bangalore, the magnanimous IT city, is experiencing the woes of urban flooding every year. This is because the city has lost its lifeline that once existed in the form of surface water bodies. Rising urbanization has destroyed the ecosystem of Bangalore that existed in the form of lakes. According to Bruhat Bengaluru Mahanagara Palike (BBMP), there has been unprecedented encroachment over lakes for building infrastructure and industries. This has led to the conversion of 19 lakes into bus stands, golf courses, playgrounds, and real estate housing. BBMP website claims that there are 210 lakes existing in the city. However, a report submitted by the CSIR-National Environmental Engineering Institute in 2020 states that out of the 210 lakes, only 21 are fit for drinking purposes. The rest of them are polluted and are not fit for drinking and about 19 lakes are encroached upon. One of the primary reasons for the recurrent menace of urban flooding in Bangalore city is due to the loss of water bodies and encroachment over these areas that prevents water flow and causes excessive waterlogging in the mainstream areas.

Solutions and Recommendations

Efforts to conserve land and its underlying resources are extremely imperative for reducing the impact of disasters and paving the way for disaster risk reduction. There have been numerous global initiatives for improving land management practices and those have significantly reduced the risk and vulnerability and thus contributed to DRR. For instance, South Korea's efforts to reverse the process of land degradation through reforestation of 2.4 mha of forests in the late 1960s (National Forest Service) and 1970s (Forest Development Program) made a successful contribution to reduce the vulnerabilities associated with disaster risk and also contributed to carbon sequestration (IPCC, 2019; Lee et al., 2018; Kim et al., 2017). Similar efforts were taken by China toward restoration in the wake of severe droughts in 1997 and massive floods in 1998 through various restoration policy initiates such as the National Forest Protection Program (NFPP), the Grain for Green, or the Conversion of Cropland to Forests and Grassland Program (GFGP) (IPCC, 2019: 396). Trees build a natural ecosystem that improves resistance to droughts, fires, and windstorms (Jactel et al., 2017) and provides stability against landslides (Kobayashi & Mori, 2017; IPCC, 2019). Conservation and prevention of soil erosion is also a critical factor to conserve land, and it has been estimated if efforts are taken toward prevention of soil erosion, it could benefit 11 km² of degraded land (Lal, 2014) and improve the resilience of approx. 3.2 billion people affected by land degradation (IPCC, 2019: 601).

Nature-based solutions to conserve land and its ecosystems can also significantly contribute to reducing hazards. As per the recent IPCC report, “coastal ecosystems can help stabilize the shorelines, protect communities against storm surge, and from tidal influenced flooding.” Numerous studies have shown that nature-based approaches can protect the coastal ecosystems. According to Narayan et al.

(2017), wetlands have helped in reducing direct flood damages by US\$ 625 million during Hurricane Sandy (USA). The study conducted by Badola and Hussain (2005) reveals the ecological services provided by the Bhitarkanika mangrove system during the super cyclone of 1999 in Odisha helped in prevention of extreme life and livelihood loss. The study revealed that in villages protected by mangroves witnessed less damage as compared to those with little or no protection (Badola & Hussain, 2005). According to Badola and Hussain (2005: 85), “economic loss witnessed per household was greatest in village that had an embankment (US\$ 153.74), followed by village with no protection (US\$ 44.02), and was lowest in the village that was protected by mangroves (\$33.31).”

It is estimated that for every dollar that is spent on disaster risk management, countries can prevent economic losses of 4 USD or more emerging out of disasters (Mechler, 2016; IPCC, 2019). It is thus imperative to identify, recognize, and respond to the vulnerabilities on land and evolve a sustainable land-use management policy that can respond to the rising threat of disasters. Communities can also act as a catalyst in drawing out systematic and sustainable ecosystem-based solution as part of land management practices that can help in disaster preparedness and mitigation. There is also a need to strengthen legal and institutional preparedness for implementing land management practices that is crucial for disaster preparedness and risk reduction. Lack of accountability and lackadaisical approach of the authorities makes the due process for implementing the law difficult and cumbersome. There is a need for institutional preparedness at all levels – state, district, sub-district, and local levels – to enforce land-use restrictions and make the authorities accountable to any sort of callous embezzlement.

Abstract

Disaster and development are inextricably interlinked. The lesser the risk in a disaster, the better the outcome of development. One of the prescribed strategies in the Sendai Framework of Action for Disaster Risk Reduction 2015–2030 is to find out community resilience mechanisms that men have been adopting as survival strategies even before the state comes to their rescue.

Coping strategies of the coastal population provide a pointer to study the resilience of certain livelihoods which can stand against the fury of disasters. Fishers, who are exploring their livelihoods in water for generations, experience the after-effects of disaster in various ways. Different research studies indicate that they adopt coping strategies to trade through the crisis.

This chapter is an attempt to find out the disaster-resilient techniques adopted by the fishers in India which has a long coastline. The author argues that documentation of community practices to save livelihoods on the eve of the onset of a disaster through micro-research will be a pointer for policymakers to take into account the mechanisms of community resilience. This will help them to

Coping strategies · Fishers · Fisherwomen · Community resilience · Disaster management · Sendai Framework

Introduction

Coping strategies of the coastal population provide a pointer to study the resilience of certain livelihoods which can stand against the fury of disasters. The devastating deluge in Kerala, India, witnessed the emergence of fishermen as saviors when hundreds of them decided to trade through flood waters to venture into areas that the Navy could not reach. They saved thousands of lives. This is an important case study for disaster research in social science. This expresses their resilience in a post-disaster situation and innovative thinking to trade through the crisis. This observation has prompted the present study.

Fish is an essential component of a balanced diet. It is full of macrominerals, vitamins, and minerals and ensures nutrition to three billion people across the globe. Sumaila and his research team have found in their study that the consumption of fish is much higher among the least developed and developing countries (Sumaila et al., 2016). For people of South Asia and Southeast Asia, fish is an essential food item in everyday meal. Fishing as a livelihood option is most common among a particular social group residing along the coast. Badjeck and his team have stated based on their repeated research that 90% of the fishers are small-scale entrepreneurs who use the conventional method of catching fish (Badjeck et al., 2010, 2013). These fishers do fishing in rivers or shallower seas within 4–5 kilometers from the coast with very little capital investment. Moreover, fish farming provides livelihood security to the poor coastal population in South Asia and Southeast Asia. Shrestha and his research team, in their research conducted in 2019, state “Aquaculture is emerging as a prime rural industry in India and Bangladesh, contributing to employment generation, food and nutritional security, poverty alleviation and an increase in export earnings” (Hossain & Shrestha, 2019: 334).

The life of a fisherman or a fisherwoman is full of struggle. From catching fish to drying them in the sun, the life of a fisher is hectic and tiring. Fisherwomen are engaged in hanging fish on a structure made of bamboo poles to sun-dry them and remove them after sun-drying. In the slack season, they stitch the fishnet. Many times, they go for scaling fish as a fish worker. They are also engaged in the sale of fish in the informal market moving from door to door. Social customs, traditions, and divisions based on caste limit the livelihood opportunities for fishers and particularly women. Despite varied roles in the fishing industry as fishers and fish workers, women’s earnings are very little compared to men. Besides, traditional perceptions

of women's role within the family combine to assign women a subservient status in the community.

Further, the fishing sector is highly affected by climatic change and the rise in sea temperature. Along with the commercialization in fishing that marginalizes small fisherfolk, the frequent occurrence of disasters along the seacoast has broken their backbone and pushed them into the vicious circle of poverty. Therefore, they develop survival strategies through "social engineering" in the community.

The number of fishers and fish farmers amounted to approximately 800 million across the world (Worldfish, 2019). In a study undertaken by the Southeast Asian Fisheries Development Center, it was stated that countries from Asia are among the major fish producers, contributing about 51.2% to the total fishery production from 2014 to 2018 (May 19, 2022) (South East Asian Fish Development Centre 2022). The South Asian region contributes 27.3% of the world's fish production (Shrestha et al., 2019: 334). This region has diversified aquatic ecosystems that encourage fishing as a livelihood for the coastal population. The population of South Asia constitutes one-fourth of the global population. This region has a long coastline of 12,000 kilometers. Bangladesh, India, Maldives, Sri Lanka, and Pakistan have shared this coastline. The other three land-locked South Asian countries, namely, Nepal, Afghanistan, and Bhutan, produce fish from their inland waterways and rivers.

The Profile of Indian Fishers

Due to its riverine ecology and 8129 kilometers (5051 miles) of coastline, India has a long history of fishing. This has become a culture in the country. Subsequently, fishing has become an intricate part of India's economy. Indians incline fishing in ponds and canals as a hobby. The country has 3827 fishing villages and 1914 traditional fish landing centers (Pai, 2017: 1). The Government of India has classified the inland water resources as rivers, canals, reservoirs, tanks and ponds, beels, oxbow lakes, derelict water, and brackish water. Total water bodies excluding rivers and canals cover an area of about seven million hectares. Odisha has been placed at the top as regards the total area of brackish water followed by Gujarat, Kerala, and West Bengal (Govt. of India, 2022). The total area of inland water resources is, thus, unevenly distributed over the country with five states, namely, Odisha, Andhra Pradesh, Gujarat, Karnataka, and West Bengal, accounting for more than half of the country's inland water bodies. India is the second largest fish-producing country in the world next to China with an annual fish production of about 9.06 million metric tons (FAO-UN, 2022).

Fishing has been treated as a sub-sector within the agricultural sector of the Indian economy, and the fishers have been designated as "fish farmers" in official records. In 2019–2020, the fishing sector made a value addition of 1.24% of the total gross value addition to the economy of the country (Economic Survey, 2021: 243). V. Vyshnavi and Rao in their research study have stated that India's water and

natural resources offer tenfold growth potential in aquaculture or farm-fishing (2016) (Sree Vyshnavi and Venkata 2016).

Economic Survey of India for the financial year 2020–2021 states “The livelihood opportunities provided by this sector have been instrumental in sustaining incomes of over 28 million people in India, especially the marginalized and vulnerable communities, and has promoted meaningful socio-economic development” (2021: 243). People are engaged in this sector as fish farmers, fishers, fish workers, and fish-food processors. Fishing has been considered a male domain for a long time; therefore, women fishers remained invisible in official statistics. However, in the late 1980s, researchers began researching them (Harper et al., 2020). Women do small catches for their home consumption and also sell a part of it to earn income for themselves and their families. Thus, women fishers have become a part of the subsistence sub-sector of the national economy. These findings underscore the role of women in the value chain of the fishing sector.

Fishing in India is a US\$ 6.73 billion major industry driven by the rapid development of brackish water aquaculture (India Brand Equity Foundation, 2021). In 2020, aquaculture accounted for 70–80% of the country’s total fishery exports.

However, the social actors in this multi-billion export industry are very poor. Their social status in India’s caste-ridden society is very low. They have little education and live under improper housing conditions. With a very low income from fishing, they support a large family as they are yet to realize the advantages of a small family. Consequently, at times, they borrow and fall into a debt trap.

Since the fishing community resides in coastal districts and states, they are most affected when disasters like cyclones or floods affect the coastal areas. The fishers lose their livelihood earnings due to the damage to boats during a cyclone or avoid going fishing due to fear of the sea in a post-disaster situation. Besides, in a post-disaster situation, the market for seafood plummets due to the fear of disease and water contamination of fish. This issue persists despite the efforts of health authorities to clear this fear and apprehension throughout the region. This further complicates the lives of those fishers who want to resume their livelihood. Low rainfall also affects fish culture.

Therefore, while strategizing management of disaster situations, it is important to keep in mind the management of the impact of disasters on the fishing community in India. The chapter attempts to document the resilience mechanisms adopted by fishers in a small administrative block of Odisha, a coastal state in India. The author argues that documentation of the best practices of communities to counter disasters will result in knowledge production and enable the fishers to learn from each other.

Disaster Management and Development

Disaster and development are inextricably interlinked. The lesser the risk in a disaster, the better the outcome of development. Therefore, the Sendai Framework of Action for Disaster Risk Reduction 2015–2030 announced a paradigm shift and

gave the call to the member states to focus more on risk reduction strategies that are to be adopted in a pre-disaster situation. In the contemporary intellectual debate on disaster mitigation, the often referred to acronym DRR (disaster risk reduction) has been replaced by new acronym, i.e., RRM (resilience building, risk reduction, and mitigation) (Amita Singh, 2018). The new paradigm prioritizes resilience building of communities against the fury of disasters, reduction of consequent risks due to disasters, and disaster mitigation.

One of the prescribed strategies in the “RRM” approach is to find out community resilience mechanisms that men have been adopting as survival strategies even before the state comes to their rescue. The RRM approach interprets “resilience” as the capacity of life to withstand nature and human frailties.

This chapter argues that the institutionalization of community resilience mechanism will go a long way in capacity-building to reduce disaster risks. This study is an attempt to find out the disaster-resilient techniques adopted by a particular community whose livelihood is most affected during a disaster. One such community is the fishing community across the globe.

The chapter has four sections. The first section gives the theoretical framework of the study. The socioeconomic condition of the fishing community in India and the issues of fishermen are given in the second section. The third section states the findings of the study, and the fourth section deals with certain actionable strategies to be adopted for the fishing community that is frequently affected by disasters.

Understanding Community Resilience

The sudden entry of disasters into one’s life and their after-effects do not make one feel that he/she is unfortunate. Disasters strike hard on a mass scale. The impact of natural disasters has been more profound during the last few years. Mega-disasters create vulnerability. Vulnerability, risk, and resilience in a disaster situation need to be understood in a different epistemological framework. “Earthquakes do not kill, but bad buildings do” (Walsh, 2010). Viewing in this framework, vulnerability has to be understood as a governance problem. Resilience is the capacity of life to withstand the condition of vulnerability through innovation and to protect oneself. The risk is proportionately related to vulnerability and resilience. Resilience reduces the risk and vulnerability of the community members. Thus, lack of law, weak governance, and a non-participative community convert a hazard into a disaster (Amita Singh, 2018: 27).

Poverty condition reduces the survival strengths of a given population when a disaster strikes. It furthers disaster risks. The population at the lowest level of the social hierarchy is the worst affected.

Though humans have experienced disasters quite often on earth, consciousness about disaster management is a twenty-first-century intellectual exercise. Prior to the millennium, disaster response was limited to short-term relief and rehabilitation.

The World Disasters Report forecasts that the heavy toll of disasters will fail our development targets (UN, 2002). The same understanding has been reiterated by the

2030 Agenda for Sustainable Development of the world. The super cyclone of 1999 and the tsunami of 2004 compelled the national governments to give serious thinking to developing a long-term strategy so that disaster losses can be reduced over time. The pedagogy of this long-term strategy of reducing losses borne out of disaster was a kind of “social engineering.” It was a macromodel or one can say a “mass culture” of disaster management.

Following this model, India enacted the Disaster Management Act of 2005. The main thrust of the disaster management exercise was a huge investment in building infrastructures like disaster shelters and relief camps, developing early warning systems, and maintaining food supply and disaster relief to rehabilitate the disaster-affected to reduce their vulnerabilities. The macromodel did not include an assessment of a disaster-prone area and its local ecology and local community practices. Gradually, this approach appeared to be devoid of humanistic concerns. The paradigm of “disaster risk reduction” gave way to a new approach that focused on documenting and analyzing resilience mechanisms practiced by different communities in different local areas.

Though disaster management has been a major concern in India since the last decade of the twentieth century, it has been realized currently that total disaster risk reduction measures are an ongoing national requirement. The 2005–2015 Agenda adopted by the international community at Hyogo expressed its commitment to “building the resilience of nations and communities to disasters.”

Further, the Sendai Framework 2015 gives a call for strengthening disaster risk governance and to “Build Back Better.” Within this framework of disaster risk reduction, the study aims to investigate the social and spatial reality.

The Sendai Framework of Action has the following essential components which will help us to frame our research questions.

1. Public policy for reducing disaster risks should take into account all dimensions of vulnerability, capacity, exposure of persons and assets, and the nature of hazards.
2. Developing a holistic public policy by integrating all sectors for strong governance to reduce disaster risks.
3. To “Build Back Better” preparedness to counter a disaster situation is significant. In this process, three steps are important: recovery, rehabilitation, and reconstruction.

Based on the Sendai Framework, the South Asian Association for Regional Cooperation has developed a Disaster Management Framework for the South Asian region. The SAARC nations arrived at a consensus on this during the 13th SAARC Summit held in [2005](#). Below are the given key points of this Framework:

- Developing a scientific group of professionals for the effective manning of the disaster management system.
- Prioritizing the reduction of disaster risks in public policies.
- Developing the strength of institutional mechanisms for disaster risk reduction.

- Empowering the communities experiencing frequent disasters.
- Expanding the scope of DRR programs.
- Enhancing the effectiveness of emergency response systems.
- Developing networks and partnerships among sovereign nations.

Against the backdrop of this understanding, this chapter argues that an area-specific approach to disaster management will motivate us to go for micro-studies in disaster management. Secondly, it emphatically states that imposing something exogenous on the local community will create anxiety in their mind. Therefore, it would be of lasting benefit for humans to manage disasters if we encourage resilient social and ecological practices adopted by the community for a long time. These practices are the resultant outcome of human innovation which has developed by using the “community spaces.” Thus, the chapter attempts to find out the social and ecological practices adopted by the fishing communities in India to curb disaster losses over time. The reasons behind focusing our study on fishers are that this section of the population depends on water bodies to earn their livelihood and is more prone to disaster risks.

The Research Setting

The study has been conducted in the state of Odisha. Odisha is the seventh largest fish-producing state in India, the first being Gujarat. Catching fish is an important pastime among the inhabitants of Odisha, though it is a livelihood option for a particular social group, *the Kaibarta*. This group has been designated as Scheduled Castes in the Census of India. Fish is a staple food for the Odias; therefore, the state has an assured market for fish. Further, all non-vegetarian population takes fish, while some of them avoid taking chicken or red meat. With the development of a variety of dishes/cuisine on fish, the demand for fish is increasing continuously. Also, the fishermen of Andhra Pradesh, West Bengal, and Chhattisgarh, the neighboring states, find the market for their fish in Odisha. The fish production in these three neighboring states has increased substantially, whereas the production in Odisha increased marginally. This is a matter of great concern as it affects the livelihoods of fishers, who constitute 3% of the total population of the state.

Home to a 4.19 crore population, Odisha is situated in the eastern part of India. It is a riverine state and has a 480 kilometer coastline. The coastal areas of Odisha have a higher density of population compared to the hilly areas. The sub-tropical climate and littoral location of the state subject it to frequent natural disasters, be it cyclones or storm surges or flashfloods or tsunamis. The rivers have a very little carrying capacity for which breached embankments cause flashfloods.

Due to the littoral location and presence of a large number of water bodies, the fisheries sector in Odisha provides livelihood opportunities to its people. We have discussed in previous paragraphs that the fisheries sector is counted as the primary sector and comes under the agriculture sector. Agriculture and allied activities in Odisha provide livelihood opportunities to 60% of its population. To make it a

vibrant sector, the Government of Odisha has been trying to augment income outcomes from the fisheries sector. Disaster creates constraints in stepping up agricultural production. The State Agricultural Policy 2020 and the Odisha Fisheries Policy 2015 show the path to sustainable development in the agricultural sector. The government has planned to achieve the average productivity of 5 tons of fish per hectare of fish farms. The mission of the state is to double the inland fish production and increase the present level of export earnings to Rs 20,000 crore (Odisha Economic Survey, 2021:96).

In terms of state gross domestic product, the share of the fisheries sector has been continuously increasing from 1.22% in 2011–2012 to 2.12% in 2018–2019 (Odisha Economic Survey, 2019: 54). The *Pioneer, the English Daily newspaper in India* writes, “It’s estimated that a population of about 12 lakh, including 9 lakh inland and 3.33 lakh in the marine sector, depends on fishing for livelihood. The inland fishermen population is highest in Chilika followed by Ganjam, Khordha, Cuttack, Kendrapara, Jajpur, and Puri (Geetanjali 2018). The marine fishermen population is highest in Baleswar, followed by Bhadrak, Jagatsinghpur, Kendrapada, Puri, and Ganjam. The fishing population is located in 3,878 villages all over the state out of which 641 are marine and 3,237 are inland villages. The literacy rate of fisherfolk is 48.15 percent and most of the fishing villages lack basic infrastructures like communication roads, electricity, drinking water, health, sanitary facility, school, and housing.”

Disasters have always affected the contribution of the fisheries sector to SGDP. The sector exhibited a growth of 12.4% in 2012–2013 but was reduced by 1.7% in 2013–2014 due to the damage to fishing equipment during the cyclone Phailin (Odisha Economic Survey, 2019: 54).

All family members of a fisherman who uses traditional fishing boats are engaged in the fishing activity in different roles. The members of the fishing community, engaged in marine fishing, are encountering many problems such as climate change, disasters, and corporatization of the fishing sector. The rise in temperature of the water makes it difficult for fishers to catch fish near the coast as there is a gradual drifting away of fishing zones. Consequently, they have to go to the relatively deep sea to catch fish. Rising sea levels, changing seasonal cycles, and climatic change patterns have adversely affected potential fishing zones in Kerala and Odisha. Numer8 Analytics Pvt. Ltd., a data science firm, has analyzed these changes (Himanshu 2020; Down to Earth, 16 July 2020).

Banerjee and Pasha in their study conducted in the Vetka village of Bhitarkanika Wildlife Sanctuary have found that fishermen’s households search for alternative livelihoods to overcome the loss of their primary occupation of fishing and dependence on forest products (Banerjee & Pasha, 2017:7). Sixty percent of the respondents in the study shared that mangroves enhance the productivity of marine and estuarine fish, prawns, and crabs which contribute to the growth of the fishery ecosystem, and with the decline of mangroves, there is also a decline in the fisheries (Banerjee & Pasha, 2017:7). During the poaching phase of the ‘olive ridley sea turtle’ and ‘crocodile census’, fishing is banned for 7 months from January to July in Bhitarkanika. The Government of Odisha compensates for this loss by providing

Rs7500 to more than 14,000 fishers. Another media report states that fishers are demanding to reduce the ban period by 2 months and enhance the compensation amount to Rs 10,000.

Displacement is a common experience with those fishers who reside in coastal areas as these areas are increasingly chosen for new industrial ventures and tourism. Further, fishing communities, who have been living along the coasts for generations, rarely have any “legal titles” to their land and, thus, do not get any compensation amount for being displaced (Naskar, 2018). Economically and politically weak, they often have little option but to leave their traditional lands in the face of pressure from the private entrepreneurs and the government.

Public Policies for the Welfare of Fishers

The Odisha Fisheries Policy 2015 is a comprehensive public policy aimed at developing livelihood opportunities for fishers in the state. The said policy emphasizes reviving primary fishers’ cooperative societies, providing financial support for cultivating finfish seeds in hatcheries and developing new ponds, and providing input support to WSHG and cooperative societies for inland fish production or pisciculture and marine fishing vessels. In other words, the public policies aimed at creating a robust support system for the fishers of Odisha to ensure the sustainability of their livelihood. Every fisher in a coastal village is provided with a marine card by which he gets subsidized rice from the PDS outfit as compensation under the World Bank-funded Integrated Coastal Zone Management Program. To meet the shortage of technical manpower in rural areas and to provide technical advice, the Government of Odisha has made provisions for higher education in fisheries. The state of Odisha collaborated with WorldFish in 2018 to conduct a study of reservoirs for cage culture 2018 and initiated the scheme of input assistance to the private sector in collaboration with primary cooperative societies. It is said cage fish culture in reservoirs is a “floating ATM.”

Below are given the names of a few welfare schemes to ensure the social security of the fishers, introduced by the Government of Odisha in Table 1.

The list in Table 1 is not exhaustive; it gives only some of the main policies. The list goes on, but targeted policies are lacking for fishers affected by natural disasters. The fishers in Odisha avail the benefits of the welfare schemes meant for Below Poverty Line (BPL) households. Pradhan Mantri Matsya Sampada Yojana of India, launched in September 2020, is also aiming at providing supplementary livelihoods to the fishers as part of agriculture and allied activities development.

To have the learning from the grassroots, the field study was conducted in the Krushna Prasad Block of Puri district of Odisha where a sizeable number of fishermen reside as natives of the villages. The study has interacted with 100 households of the fishing community in different villages. The study has adopted a qualitative research design that has captured the techniques adopted by the fishermen throughout the year to enhance their resilience against disasters. The research tools used in the study were focus group discussion (FGD), interaction with panchayat

Table 1 Social security for fishers by the state

Sl. no.	Social security policies for fishers	Year of introduction
	Mukhyamantri Krishi Udyog Yojana	1996
1.	Matsya Pokhari Yojana	2017–2018
	Matsyajibi Unnayana Yojana	2016–2017
2.	Financial assistance to WSHG for pisciculture in GP tanks/ponds	2020–2021
3.	Input assistance to private entrepreneurs in collaboration with WSHG/Primary Fishermen Cooperative Societies for cage fish culture in reservoirs	2018–2019
4.	Financial assistance for the construction of new inland ponds	10th Plan (2002–2007)
5.	Financial assistance for the construction of freshwater finfish seed hatcheries	10th Plan (2002–2007)
6.	Financial assistance for fishing equipment	2021–2022
7.	Reviving Fisheries Cooperative Societies	2020–2021
8.	Livelihood support to marine fishers during a ban period	2016–2017
9.	Financial support for deep-sea fishing vessels for fishermen	2020–2021

leaders and important personalities in the villages, and a case study method to document narratives of some fishermen which contains important findings for our study.

The following research questions were explored during our field study.

- What is the socioeconomic status of the fishing community?
- What is the socioeconomic status of fisherwomen?
- What is the impact of disasters on fisher's households?
- What disaster-resilient practices they have been adopting for a long time to stand against a disaster until the administration comes to their assistance?

Discussions

The research study was conducted in Krishnaprasad Block of Puri district of Odisha. Therefore, a discussion on the Puri district is essential to understand the social and ecological nature of the study area. In 1995, for administration convenience, the Puri district was divided into three new districts.

- i. Nayagarh.
- ii. Khurda.
- iii. Puri.

Currently, Puri district has 1714 villages, 1 subdivision, 11 tehsils, 11 blocks, and 1 municipality. It shows that Puri is primarily having a majority of the rural population. 16.9 lakh people reside in the district. The district has a literacy rate of

85.37%. The study area, the Krushnaprasad block, is located in the Puri Sadar subdivision. The conservative society of Puri is reflected in its sex ratio which is 963 females for 1000 males.

The research field area, i.e., Krushnaprasad Block, has 83 villages whose populations range from a minimum of 48 persons to 3222 in Maludkhas village. 42.5% of the population in Maludkhas are Scheduled Castes who have a literacy rate of 82.39%. The block is a rural area having 20 panchayats and no urban area. Twenty-four percent of its population are Scheduled Castes. Only 186 Scheduled Tribes live in this block. However, the literacy rate is 81.51% as per the 2011 census. In 2011, a total of 12,088 families were residing in Krishna Prasad Block (Census of Krishna Prasad Block 2011). The average sex ratio of Krishna Prasad Block is 942. In all panchayats, the ruling political party Biju Janata Dal has a stronghold.

According to the 2011 Census of India, Krushnaprasad Block had a population of 57,505, out of which males constitute 51% of the population and females 49% (2011). It has six marine fishing villages. Twelve percent of the households in the block belong to fisherfolks. In other words, 11% of fishermen in the Puri district reside in this block (Ammini et al., 2008). Four percent of fishermen in this block have formal schooling. Thirty-one percent of fishermen are engaged in actual fishing. Seventy-nine percent of fishermen have a gillnet for fishing. The respondents shared that due to climatic changes, they have to spend more time finding fish. This results in investing more fuel and getting exposed to unpredictable weather conditions. They also shared that they have abject sales margins and have to navigate through middlemen. Sometimes, they migrate to other coasts in search of fish.

It's a general practice among the fishers to respond to the early warning announcements made by the government before the onset of a cyclone. However, the fishers make themselves prepared when they visualize the onset of a cyclone. They call this natural phenomenon "Mahuli" which is the weather condition before the onset of a heavy storm and wind blows from the North. Our research team found the following community practices followed by fishermen when they apprehend the coming of "Mahuli":

- The majority of fishermen use country boats though some of them are using mechanized boats whose engine costs around 3lakhs. When they see the onset of "Mahuli," they take out the engine from the boat and keep it in a safe place in their house.
- Secondly, they choose a place to develop an artificial bay/harbor on the shore. They use gunny bags and grass patches to block it so that seawater does not enter in a large amount during a heavy storm. This creates a strong wall for the bay or a condition of the artificial harbor. After this, they keep the boats there and tie them strongly together with some strong support.
- The alternative practice adopted by them is that they prepare strong carriers with wood and grass which can roll on the sand to carry boats from the seashore to a far-off place. Precisely speaking, wood carriers work as vehicles to carry boats.

- After the shifting of the fishing-boats to a distant place away from the sea, the fishers turn the boat upside down on the sand to face the heavy storm so that wind does not flow away from the boats from them.
- In such a situation, they opt for the distressed sale of their fish. Due to the frequent occurrence of natural disasters, the fishermen experience distress sales quite often.
- Before the shift to the cyclone shelter made by the government, they keep their utensils and valuables in a safe place in someone's pucca house.
- These fishermen are always in a debt trap. Their debts are small debts that range between Rs 30,000 and Rs. 50,000. But, they are not in a condition for years together to pay back the debt. Therefore, indebtedness is a regular feature in fishermen's lives. This is the major reason behind their distress migration for livelihood.
- The majority of the fishers are marginal fish farmers having two to three nets. They own 1 acre to 1.5 acres of land. The fishermen with small boats experience a variety of hazards as they avoid going to the deep sea and operate near the coast. If the net catches turtles, it gets damaged. Till they arrange a new net, they remain at home without any livelihood earnings. In contrast to this, entrepreneurs with trawlers do not experience such hurdles in their business as they go deep inside the sea.
- Further, the introduction of modern technology and equipment like gillnets, fishing gear, etc. has happened due to the modernization of the fishing sector. Small and marginal fishers lack the finance to have access to this modern equipment. This has resulted in a loss of family businesses and converted them into workers in privately owned big trawlers.
- Fisherwomen have very little access to credits and fall prey to the informal loan network. They fall into the debt trap by borrowing money from the village money lender at a higher rate of interest. They continue with their trade with the help of the male members of the community. Many women own boats and nets but are unable to go fishing independently. Thus, fishing remains a male activity in the community. This has worked as a barrier to women's development in the community.
- In spite of the supportive public policies of the Government of Odisha, there has been no visible improvement in the economic condition of the fisher's households.

Way Forward

During our conversation, the fishers shared that if the administration provides assistance to support and sustain their community practices to stand against a disaster, it would be of great help to them. They expressed that such disaster-resilient practices followed in different countries are required to be documented through research. The traditional community practices, if supported along with knowledge on the use of modern technology, will make them stronger by developing

their resilience against disasters. Institutionalizing community resilience practices would help us to prepare ourselves to counter frequent disasters.

Further, recognition of rights of access to resources of traditional fishing communities is of foremost priority in a democratic state. Fishing involves long hours and strenuous work in a marine environment that may get disturbed suddenly by atmospheric conditions. Therefore, injury and fatality rates are much higher in the fishing sector. The International Labour Organization has taken note of these hazards to fishers and developed the ILO Fishing Convention 2007 (no. 188) and ILO Recommendations (Convention No. 199) for developing a social security net for regulating the living and working standards of fishers. The objectives of these Conventions are to ensure a decent standard of work conditions for fishers on board the fishing vessels, conditions of service, accommodation and food, occupational safety, and healthcare. Governance reforms are required as per these Conventions.

Conclusion

Each ecosystem and the fishers in it have specific problems. Therefore, an area-specific approach in public policies will help the fisher's households to "Build Back Better" in a post-disaster situation.

Abstract

Urban cities which look smart with towering structures, massive infrastructure, have their backbone in the migrant labor, but they are also the ones which are most vulnerable to the plight of disasters. Migrant labor move to cities for better livelihood and income opportunities, but the city's landscape with its high rental rates, unplanned growth, does not accommodate the needs of the migrant population thus pushing them to periphery. Migrant communities usually occupy spaces that are hazard-prone areas and are vulnerable to disaster risk. These spaces come up as squatters, slums, and jhuggis that lack formal recognition of ownership rights with dwindled space, lack of basic infrastructure, and have higher population density that adds to the vulnerability of migrant communities. This affects the coping capacity of the migrant communities in the aftermath of a disaster, and it also poses a greater risk to these vulnerable communities in disaster response and recovery. This chapter argues that the migrant communities occupying spaces in hazard-prone areas differ in their context and vulnerability; therefore, there is no one-size-fits-all approach in disaster risk management. It therefore needs a bottom-up community-based participatory approach that integrates the efforts of communities in disaster preparedness, risk, and resilience.

Introduction

The contribution of migrant labor to the formation of cities has been magnanimous. It cannot be denied that behind the veil of glitterati of smart cities lies the gigantic labor of migrants that has helped in shaping up of the cities to its livable form of enormous infrastructure, highways, urban centers, ports, real estate, industries, and townships. As cities expand, their share of migrant population also increases and contributes to the building up of its infrastructure and housing needs. For instance, Gurugram which is known as the Millennium City of India witnessed a massive rise of migrants with its in-migration levels escalating to 29 per cent between 2001 and 2011 ([Economic Survey 2016–2017](#)). The Census 2011 data on migration reveals that growth rate for migrant labor increased from 2.4 per cent per annum between 1991 and 2001 to 4.5 per cent in the next decade from 2001 to 2011. However, this runs contrary to the Economic Survey 2016–2017 data that says that the share of migrant population is more than 100 million as labor migration in India tends to be circular in nature, i.e., moving from one place to another for better livelihood and economic opportunities. The data brought about by the Economic Survey 2016–2017 on the rate of migration examines the unreserved railway passenger data between 2011 and 2016 and brings to light that Delhi accounted for maximum in-migration population followed by Maharashtra, Goa, and Tamil Nadu in 2015–2016. This was juxtaposed to the Hindi heartland states like Uttar Pradesh and Bihar that accounted for maximum population of total-out migrants.

Cities which look smart with massive, gigantic structures have their backbone in the migrant labor, but they are also most vulnerable to disasters due to their unplanned growth and expansion. The problem of disaster management in cities has much to do with rural-urban migration, high rental rates, and proliferation of lower-income households living in slums. Urban cities offer huge potential to migrants to scale up their income opportunities and economic well-being, but these spaces are also marked by vulnerability and disaster risk. Due to unavailability of adequate housing and higher cost of living, migrants are forced to live outside the cities around the peripheral areas occupying a city's heartland. Most often, these spaces are characterized as squatters, jhuggis, and slums that are surrounded around railway tracks, ill-drained marshland, coastal wetland, flood-prone areas, mangroves, and landfill sites. These areas make the living condition of migrants prone to climate and disaster risk because they occupy spaces that are vulnerable and are exposed to incessant flooding in low-lying areas, sea-level rise, landslides, and unabated fires.

Vulnerability of migrants was exposed during the Covid-19 pandemic as suddenly migrant population who are mostly informal workers and daily wage earners were left out of jobs. The immediate response to the pandemic across the globe was

overdriven by the imposition of series of lockdown and containment measures that left the vulnerable communities in a state of apprehension. The informal sector was the worst hit as workers were left either without jobs or without an assured income to meet their daily and basic livelihood measures such as expenditures for rent, water, electricity, etc. The situation in India was precarious as a sudden lockdown by the state turned out to be one of the biggest humanitarian disasters (Chugh, 2022). It is estimated that by May 2020, approx. 10.4 million population moved from urban to rural areas (Singh et al., 2020; Choudhury et al., 2022). Urban migrants occupying spaces in squatters and informal settlements were forced to leave their homes due to lack of secure tenure and loss of income (Choudhury et al., 2022). Singh (2021: 160) argues that “Covid-19 pandemic came out in the form of sudden lockdown that led to exodus of migrant labour and the only relief that was sought was not being charged any rent during the lockdown period, but without any security or enforcement they were soon thrown out by the landlords.”

Global frameworks and agreements have highlighted the need for a more community-based preventive approach by including the vulnerable population including migrants as an important stakeholder to achieve the targets of disaster risk reduction. It has been highlighted by the Sendai Framework for Disaster Risk Reduction (SFDRR, 2015–30) that a multihazard, multisectoral, and inclusive approach has to be incorporated that works in unison with the needs and priorities of migrant population to reduce disaster risk. Sustainable Development Goals (SDGs 2015–2030, Goal 11) have also underpinned the need for safe and resilient settlements with access to safe and affordable housing and improvement of slums with basic infrastructure and integrating it with goals of the Sendai framework to have a holistic disaster risk management framework. It also highlighted (Goal 1, 5, 13) formalization of land tenure through guaranteeing ownership and control over land and integrating it with strengthening disaster resilience of vulnerable communities.

Vulnerability of Migrants in Urban Spaces

Slums and squatter settlements generally expand near the peripheries of cities; they occupy spaces in low-lying and vulnerable areas that are prone to the vagaries of unprecedented disasters. These unmitigated urban expansions around the periphery of cities are marked with sociolegal vulnerabilities that add to disaster risk. These habited areas are clustered together with dilapidated and inhumane living conditions which remain outside the bulwark of the local administration. These spaces mostly remain unrecorded and mapped where the residents who occupy these spaces do not have ownership and other legal rights. When a disaster strikes, the migrant population residing in these spaces are most vulnerable to its impact, and there is no effort by the administrative machinery to unwind its repercussions. For instance, the Ghazipur landfill site in East Delhi which was commissioned back in 1984 for solid waste management has now become an abode for migrants as they hail mostly from Uttarakhand, Bihar, Uttar Pradesh, and West Bengal. Most of the migrants residing in this hazard-prone site are manual scavengers and rag pickers. The striking

Ghazipur landfill has become one of the most hazard-prone landfill site that is emitting harmful and poisonous methane gas which is detrimental for the ecosystem and is harmful for the well-being of migrant communities. They are forced to live in these shanty, dilapidated spaces with no proper drainage, sanitation, and pucca houses in a natural hazard-prone area as it is exposed to exacerbated fire accidents. The National Green Tribunal (Before the National Green Tribunal Principal Bench, New Delhi. Item No. 15. Original Application No. 288/2022.) has marked this landfill site as a “time bomb” as it continuously releases the poisonous methane gas that is averse to causing fires and explosion. The height of the landfill site with garbage and toxic waste all around is increasing every year thus turning out to be a health hazard and resulting in increased fire incidents every year.

Apart from the vulnerability of natural hazards in these urban spaces occupied by migrants, the impact of disasters on the informal settlements is much higher in its intensity and proportion as compared to other settlements due to absence of secure land tenure, inhumane livelihood conditions, exclusion, and lack of preparedness. The onslaught of Covid-19 pandemic was a litmus test to the resilience and limited capacity of communities living in informal settlements that mostly constituted migrant population. Informal settlements wrestled with excessive virus transmission due to challenges of high population density and inadequate access to water and sanitation, which made them vulnerable to keeping social distancing and maintaining hygiene (Wilkinson, 2020). Covid-19 pandemic turned out to be a major hotspot in urban informal settlements. For instance, Dharavi (Mumbai, India) which is Asia’s largest urban slum witnessed the worst crisis, and the biggest challenge it faced was how to maintain hygiene and sanitation amid prodigious population density of 354,167 per square km.

As per the World Cities report (2020), 1.6 billion people or 20 percent of the world’s population live in slums. This estimate will further intensify due to shrinkage of livable space in urban areas and urban expansion will more likely extend in low and middle-income countries. These areas remain unrecorded and are neglected by the administration due to failure of formal land markets and planning. UN-Habitat (2003) has defined a slum household that is marked by absence of a resilient infrastructure, access to clean water, sanitation, sufficient living space, and a secure tenure. UN-Habitat statistics reveals that in 2018 approximately 24 percent of the urban population were living in informal settlements and out of these, approximately 54 percent and 38 percent of urban population were living in sub-Saharan Africa and South Asia, respectively. Secure land tenure is not only important from the vantage point of ensuring legal protection from eviction, land grabbing, or displacement, but it is also a sine qua non for providing improvement in housing and physical capital (i.e., access to water, electricity, sanitation, and drainage) (Field, 2005; Gelder, 2009; Nakamura, 2014).

Quality of housing is essential from the perspective of mitigation of vulnerability to disaster hazards such as fire and flooding (McDermott et al., 2021). Secure land rights are inextricably linked to improvement in housing and resilient infrastructure. Investment in housing and infrastructure is a gradual and incremental process that makes the communities resilient and prepared against impending disaster risk.

However, insecure land tenure inhibits the local communities from investing in land and other housing infrastructure as they mostly occupy public land that is averse to eviction and dispossession without any sort of fiscal and rehabilitation support. The potential and lack of resources to stay prepared against disasters and invest in disaster mitigation is more severe in instances where land tenure is insecure (Burby et al., 2003). Intensification of urban slums near low-lying areas and landfill sites makes them vulnerable to increased disaster risk with no motivation to invest in housing. Field (2005) examined a nationwide titling program in Peru to highlight an intricate relationship between tenure security and investment in housing and found that guaranteeing property rights led to an increase in investment in housing in informal settlement. It has also been argued by Nakamura (2014) that tenure formalization initiatives undertaken in India have led to stimulation of housing investments.

Cities across the world occupy just 3 percent of land area which means that urban sprawl is likely to occur in this limited space, thus putting pressure on cities to strive for sustainable living. These informal settlements remain outside the glitterati of megacities and occupy spaces in hazard-prone and low-lying areas due to higher affordability and shrinking of livable space in cities. These spaces remain outside the formal land markets with no enforcement of land administration, land-use planning, and building codes. Mitchell et al. (2015: 191) has argued that “*impact of natural disasters is magnified by inappropriate land-use planning...hazard risk is the cumulative result of deficiencies in previous decisions about land use, land development and building standards.*”

If one looks at the statistics of world’s largest informal settlements in terms of population, they largely occupy spaces in low- and middle-income countries. World’s largest slums lie predominantly in the Africa and Asia region, and these are Manshiyat Nasser, Cairo (2.62 L); Khayellitsha, Cape Town (4 L to 1.2 Mn); Tondo, Manila (6 L); Dharavi, Mumbai (1 Mn); Kibera, Nairobi (1.5 Mn), and Orangi Town, Karachi (1.5 Mn to 2.4 Mn). There is a close link between migrant population occupying spaces in informal settlements and disaster risk as the occurrence and intensity of disasters is much more in low- and middle-income countries, and this is evident from the fact that, between 2000 and 2019, the world recorded 7348 disasters, out of which Asia suffered the maximum with 3068 disasters, followed by Americas (1756) and Africa (1192). In terms of economic loss also, Asia and Pacific suffered the maximum loss as the region lost on an average of 1.6 percent of its GDP to disasters (UNDRR, 2022). This is followed by Africa which is the second most affected region globally, with an economic loss of 0.6 percent of its GDP (UNDRR, 2022). Economic loss due to disasters is relatively more in low and middle-income countries as they suffer 0.8 to 1 percent of their national GDP to disasters as compared to 0.1 to 0.3 percent in high-income countries (Ibid). This is only a tip of the iceberg as there are major lapses by the government to report disaster economic losses. For instance, between 2000 and 2019, only 35 percent and 23 percent of disaster events reported any data for economic losses in Africa and South Asia, respectively (UNDRR, 2020).

Vulnerability During Disaster Response: How to Build Back Better?

It is well perceived that those who are at the margins are the most vulnerable to the impact of a disaster. Disaster impacts the coping capacity of the communities to deal with a sudden catastrophe or outbreak, and thus the Sendai Framework has explicitly mentioned, in its Priority 4, the need to strengthen disaster preparedness for response and to “Build Back Better” through integration of DRR into development measures. Migrants generally settle in areas that do not have the requisite infrastructure to cope with the impact of a disaster, and they also face difficulty in disaster recovery and response as they do not have secure land rights as evidence to prove their ownership. These areas where migrants settle are outside the formalization process, and the local administration does not take necessary steps to recognize these spaces. Lack of secure land title significantly impacts the communities at the periphery who live in informal settlements. Mitchell (2009: 6) argues that *“a secure land title is necessary to respond to disasters in terms of allocating assistance and retribution in reinstating homes and livelihood.”* Legalized land tenure is also important for using land as a collateral to cope with the aftermath of a disaster.

Without any formal recognition of land laws, communities lose their pristine land which is the only source of sustenance and is also crucial for recovery and resilience. The Asian Tsunami of 2004 was most devastating and lethal as more than 228,000 people lost their lives in 14 countries across the Asian region. The pervasive impact of the tsunami was all the more pernicious for the communities located at the periphery due to lack of secure land tenure or loss of title documents during the disaster. This led to land disputes in Aceh (Indonesia) caused by land grabbers as there was lack of clarity over land and prevalence of uncertain inheritance rights (Mitchell, 2009). Many native communities had been occupying land for generations without any formal records; thus, tsunami paved the way for land grabbers to displace native communities – thus transforming public beaches into private goods (Handmer et al., 2006). Mitchell (2009: 4) argues that disasters also caused significant impact on the capacity of land administration systems due to damage to land records, inaccuracy in recording spatial information due to loss of land, damage to boundary and survey marks, and loss of administrative staff.

Impact of insecure land tenure on the resilience of communities was also witnessed during the Bhuj earthquake of 2001 as much of the government land identified in the land records was occupied by informal settlers (UN-Habitat, 2010; Burns, 2010). This paved the way for formalization and regularization of land tenure post 2001 disaster. Legalization of land tenure was primarily *in situ* to respond to the needs of informal settlers (*Ibid*). Similar risk was also faced by the communities in 2013 Typhoon Haiyan that comprised largely of informal settlements as their effort for recovery and reconstruction was severed due to lack of secure tenure (Sarmiento et al., 2020).

The Thomas Fire in Ventura County, California, in 2017 that lasted for more than 40 days resulting in total damage of \$ 2.2 billion forcing 104,000 habitants to

evacuate caused irreparable damage to immigrants in disaster relief, response, and rescue operations (Mendez et al., 2020). California is abode to an approximately 2.6 million undocumented Latino/immigrants, mostly farmworkers or involved in housekeeping jobs (*Ibid*). These immigrants were excluded from receiving disaster relief aid from the Federal Emergency Management Agency and the Disaster Unemployment Assistance program (*Ibid*). Even the disaster warnings that were issued remained out of reach for these immigrants as they were not issued in their native language. These immigrants were forced to live in these natural hazard-prone areas that were vulnerable to forest fires. It is an undeniable fact that when a disaster strikes the cost of it is proportionately higher for those who are at the margins of the governance paradigm. The State also treats them differentially in providing them access to relief and response measures as they do not have the requisite documents that validate their citizenship and legal ownership rights.

Community-Based Efforts in Disaster Risk Management: Lessons Learned

In the context of embedded vulnerabilities of migrant population and intensification of disasters, the solution lies in a nuanced approach that integrates community-based efforts in disaster risk management. This needs a holistic background and understanding of deep entrenched vulnerabilities of migrant population occupying spaces that are informal in nature and prone to natural hazards. These vulnerabilities can range from physical and social marginalization, cultural and language constraints, and absence of legal rights to claim ownership which is important from the vantage point of loss and damage assessment during relief and response measures. Communities have a better understanding of their vulnerabilities and how to deal with these vulnerabilities when a disaster strikes and recover from its impact. Community-based organizations have a stronger cultural understanding of the differentiated vulnerabilities and engage with the communities to identify, analyze, monitor, and evaluate disaster risks (Mendez et al., 2020). Thus, it is important to draw on the knowledge and adaptive capacity of the communities in disaster preparedness, mitigation, and response.

A case study of Portmore, Jamaica (North America), reveals that concerted efforts of communities with different national and local government agencies can reduce disaster risk by securing land tenure. This initiative was undertaken in 2015 by Habitat for Humanity known as Building Resilience and Capacities for Emerging Disasters (BRACED). Approximately one-fourth of the three million population were living in 700 informal settlements that were precarious to hazards with no compliance for building and safety standards. As per the Habitat for Humanity, approximately 45% of the land in the country is unregistered. The project adopted an inclusive and participatory community-based approach by focusing on improving tenure security to improving resilience to disasters. Technology was used as a tool for engaging communities in the formalization process. Through participatory governance measures, communities were engaged in enumeration and mapping of areas

to be undertaken for tenure formalization and enhancing disaster resilience. Formalization of land tenure braced up the communities' efforts to augment access to basic infrastructural needs such as access to drainage, water pipe, and electricity. Sarmiento et al. (2020) argue that ensuring tenure security along with making investments such as addition of brackets, hurricane straps were adopted as preemptive measures to reduce disaster risk and simultaneously reduce vulnerability of informal settlements.

Another case study of Vietnam's National Urban Upgrading Programs (VUUP) in the Mekong Delta Region (MDR), implemented by the World Bank since 2004, has engaged communities in the slum-upgrading process to enhance disaster resilience. The estimated cost of the project was 418 million USD with an additional funding of 160 million USD by International Development Association (IDA) (Garschagen, 2015). Vietnam with an extensive coastline of 3260 kms is one of the most severe and hazard-prone country in the Asia Pacific region. Approximately nine million human population (UN-Habitat) in Vietnam live in informal settlements close to the coasts, low-lying vulnerable areas, and are exposed to hydrometeorological hazards that include cyclones, coastal erosion, floods, and landslides. The complex nature of granting land-use certificates and going through inadvertent insurmountable procedures where the onus for verification of permanent residency lies on the claimant led to the rise of informal settlements (Minnery et al., 2013). The project aimed at in situ upgrading of low-income communities by improvising basic infrastructure and focusing on environment sustainability and institutional strengthening in four cities Can Tho, Hai Phong, Nam Dinh, and Ho Chi Minh. A multisectoral approach was applied by engaging communities with local government to enhance basic infrastructure that aimed at improving the living conditions of inhabitants (Baker, 2012). It aimed at engaging and working with local communities in the planning, design, and implementation of the project (*Ibid*).

These case studies have highlighted that there is no one-size-fits-all or a universally accepted solution for improving the resilience of vulnerable migrant communities and integrating it with DRR efforts. Therefore, there is a need not only to strengthen land laws but also to look closely at the contextualization of migrant communities. They have undertaken different methods like using technology for integrating government and community efforts and slum-upgrading for improving disaster resilience. But a commonality that strikes a cord between all such initiatives is that the role of communities remains the linchpin for reducing the risk and vulnerabilities. There can be inter-regional and intraregional differential understanding of how the spaces occupied by migrants look like based on the various multi-dimensional factors bringing in social, cultural, and disaster vulnerability. Migrant settlement located at the peripheries of urbanized metropolitan city like New Delhi will vary from a squatter located close to the coastal region of Mumbai in terms of social, cultural, and hazard vulnerability. For instance, the coastal city of Mumbai faces immense challenge of hydroclimatic hazards whereas Delhi which is in seismic zone IV faces the challenge of seismic hazards, continuous heat waves, and air pollution.

Conclusion

Community participation should be embedded within the efforts of the state to integrate people-centered community-based efforts in disaster risk reduction. It is the community which is the first responder to avert or deal with any crisis or disaster. Community not only lies at the essence of any public policy framework, but is also the spirit behind how to stay prepared, deal, and recover from the setbacks of a crisis. The HFA (2005–2015) explicitly underlined the need to strengthen community resilience to deal with disasters. This was also recapitulated in the SFDRR (2015–2030) that aimed to integrate “disaster risk reduction efforts into development measures, making nations and communities resilient to disasters.” Migrants constitute an important stakeholder in disaster risk management at the local level, and therefore there is a need to understand their differentiated vulnerabilities, cultural context, and engage with them to reduce disaster risk and strengthen resilience.

Abstract

Natural disasters were there from the very existence of the human kind and nature in the universe. No place in the world is a disaster-free zone. But, how the challenge is faced by mankind is a matter of great concern. This chapter analyzes how Kerala, geographically situated in a natural disaster-prone area, fought three calamities in 2018, viz., (1) the floods, (2) the Nipah virus, and (3) Covid-19 epidemic, bravely. It focusses on how Kerala society has resilience against calamities and the role of local governments (panchayats) in saving people's lives. The People's Plan Campaign, initiated by the Kerala State Planning Board in August 1996, aimed at strengthening the decentralization process through the local bodies, and it has become an integral part of people's lives in the state. The chapter highlights the success, the state achieved, during calamities in saving people's lives and property, emphasizing the need that the other parts of the country could follow the Kerala model of development, particularly in dealing with disasters of any nature.

Introduction

The Kerala state, with a population of 3.46 crores (2018), is geographically situated in a natural disaster-prone area – between 590 kms coastal and 450 kms along the eastern side with Western Ghats. As the climate change is a reality, Kerala has become a victim of disasters. Moreover, Keralites are all over India. Globally in all the countries, there are Malayalees. They are students, employees, employers, and citizens in foreign countries. Therefore, it is no surprise that our students came from Wuhan in January 2020 and the Covid-19 pandemic appeared in Kerala for the first time in India. This chapter focuses on how Kerala society has resilience against calamities and the role of local governments (panchayats) in saving people's lives since 2018.

Natural disasters like cyclones, floods, and landslides which have hit Kerala frequently for the last few years and epidemics like Nipah and Covid-19 have brought the best out of the local bodies which have played a significant role in managing them and bringing succor to the ravaged land and people. The local bodies were primarily responsible for making the people, especially youths, rise like a man forgetting the caste, communal, social, or political differences that divide the state during normal times.

In the year 2018, Kerala had two calamities: (1) the floods and (2) the Nipah virus. The floods in 2018 killed some 500 people, caused more than 5000 landslides, impacted three-fourths of the villages in the state, and temporarily displaced almost 1.5 million people. The total damage and losses were estimated to be worth USD 3.8 billion.

Nipah virus is a deadly pandemic caused by the Nipah virus transmitted from animals and birds. It broke out in Kozhikode and Malappuram districts in 2018, but it was contained quickly.

In 2019 Kerala had the worst flood calamity, more than 120 dead and 1780 houses collapsed in northern Kerala – Malappuram and Wayanad.

Kerala was the first state in the country to report a Covid-19-positive case in January 2020 and quickly declared it a health emergency. Sceptics were later proved wrong as in a few weeks' time the virus spread like a tornado. From end of February, the cases rose steeply in Kerala and topped the charts along with Maharashtra. During the second wave that started from Pathanamthitta, the government launched an action plan consisting of contact tracing of patients, home isolation of primary/secondary contacts, and increasing testing numbers.

How the Panchayats Came to the Forefront

Kerala has been a forerunner of the new panchayats. As early as 1958, the District Councils Bill was introduced in the Kerala state assembly with a view to bring about district government, coordinating the functions of the panchayats and municipalities at the village and district levels.

The election to the district councils on January 21, 1991, was the first election after vesting the district councils with enormous powers (about 150 subjects have been transferred from the state to the districts), making Kerala the federation of districts, a unique feature in the local government system in India. The Institute of Social Sciences conducted a survey of the 1991 election, and it revealed many interesting dimensions of Kerala's sociopolitical and economic aspects as well as the emerging characteristics of political leadership. Out of the 366 members interviewed, 126 were women and 240 were men. The women members were about 34 percent of the total elected members., which was far above the 30 percent reservation for women then being discussed nationally (Institute of Social Sciences, 1991). Today in local governments in Kerala, 52 percent of women get elected. This means a large number of women contest from non-reserved constituencies against men and win the election.

The People's Plan Campaign, initiated by the Kerala State Planning Board in August 1996, aimed at strengthening the decentralization process through the local bodies becomes an integral part of people's lives in the state.

The Kerala People's Plan campaign has brought to the forefront the fundamental role of certain variables: best practices at the microlevel, "think tank" at the state level, civil society associations, political and democratic consciousness of the citizens, and, above all, political will.

Today, Kerala is on the front line in conducting regular elections to the local governments. Kerala has 18,372 elected members in the local governments, and out of this, 15,962 are in the village panchayats.

The undisputable lesson from the people's plan exercise in Kerala was that planning must begin at the grassroots – voicing the survival concerns of the people and prioritizing their needs and choices – and both must be formulated and implemented by people themselves. Apart from electing representatives during election time, participation encapsulates the spirit of democracy, the right to be heard in the public sphere and to play a critical role in decision-making. Such participation takes place only when ordinary people assemble in the Grama Sabhas at regular intervals to discuss, decide, prioritize, and monitor the activities of the panchayat, when nonofficial experts and volunteers prepare the reports, formulate projects, and draft the local plans following a people-centered approach.

In Kerala, the officers play a key role. They spearhead fascinating innovations and win the trust of the local self-governments. Kerala provided a lead in demonstrating how officials can work in cooperation with nonofficials to achieve the set goals.

According to American sociologist Patrick Heller, "nowhere in India are local governments as resourced and as capable as in Kerala... Whether in focalizing containment efforts in hotspots, tracking down those who have been exposed or managing the broad array of direct benefits that have been distributed to migrant workers, the elderly and differently abled, the key has been the capacity of state actors and civil society partners to coordinate their efforts at the level of Panchayats, district and municipalities" (The Hindu, 2020).

Kerala's evolution of a strong public health system laid the foundation for the state to address this current pandemic crisis. On the plank of its *Aardram* mission that focused on providing quality healthcare accessible to the poorest of the poor, 500 primary health centers were upgraded to community health centers, and over 170 health centers in the state were converted into family health centers.

Since the local self-governments in Kerala have the capacity through its skilled human resources, infrastructure, citizen support, and financial base, the panchayats successfully address problems that seem insurmountable. The local government landscape enabled the state to oversee and focus on crisis management holistically. The local government setup along with the strong and proactive support of the district administrative machinery ensured that these measures reached each and every village panchayat or urban part of the state.

According to the Post Disaster Needs Assessment (PDNA) that was prepared by United Nations, ADB, government of Kerala, the World Bank, and the European Union after the 2018 floods, the local governments had a paramount role in achieving the vision of *Nava Keralam* (New Kerala). The report recognized the panchayats' role in restoring services, reconstructing houses, and supporting local economic recovery and other public services. It said that the local government actions "will go a long way not only in restoring normalcy but also in rebuilding a resilient Kerala," stated the PDNA report.

At the panchayat level, ASHA and *Kudumbashree* workers have been given the responsibility to track people who have returned from foreign countries in their areas. A unique program in Kerala is the community kitchens in every panchayat, powered by the network of the *Kudumbashree*. The response to the call for volunteers has been overwhelming.

The Constitution of India (11th Schedule: Article 243G, Subject no.23) stipulates that "Health and sanitation, including hospitals, primary health centers and dispensaries" come under the responsibility of local self-governments, the panchayats. Accordingly, the grassroots institutions for public health service delivery in India, namely, health subcenters, primary health centers (PHC), and community health centers (CHC), should ideally come under the administrative jurisdiction of the Panchayati Raj system.

It may be mentioned here that only in Kerala all the panchayats have the primary health centers. Not only that every panchayat has subcenters and all are well-equipped with medical doctors, paramedics, well-functioning office, and so on. Thus in the panchayats, these primary health centers are the epicenter for the victims of the pandemic.

Kerala's public health system (PHS) comes under the local governments. The PHS network consists of 6000 doctors, 9000 nurses, and 15,000 health workers. Then there is a second line of health workers: Asha workers, *Kudumbasree* health volunteers, Anganwadi workers, hospital development committee members, palliative volunteers, and health activists.

The way panchayats – its elected members, Gram Sabha members – deal with the present crisis is exemplary. Here is a report from the field.

According to a field report, “Kerala Covid fight starts bottom up, panchayats lead the way”: “For the hard-pressed State Government officials say the active support of the local bodies has come as a big boost. On the ground leading the fights are panchayats” (Shaju Philip, 2021).

Mayyil panchayat in Kannur, with a population of 31,000 and 18 wards, has set up a 24 x 7 call center of its own and deployed a rapid response team (RRT) with 140 active volunteers, including college students, youth leaders, daily wagers, and taxi drivers. Every ward has “jagratha committees” comprising a local panchayat member. The focus is on monitoring the Covid-19 cases.

According to K. K. Rishna, panchayat president, “Our call centre is for people to inform us about all their requirements – food, medicine and vehicles to go for Covid tests and vaccination. Three persons have been deployed at the center to alert RRT teams in each ward on the requests received. The idea is to ensure that people do not come out of their homes for even a minor requirement” (Sabrang, 2021).

The panchayat had only one ambulance at the primary health center. But when we asked for more vehicles, a local organization handed over its ambulance and several others their vehicles and taxis.

The elected members of the Kerala village panchayats take courageous efforts to save the people during calamity. Take the case of Ms. Sajimol Francis, member of the Alappuzha district panchayat, who got elected first in 2005 as village panchayat member. During devastating floods in Kerala in August 2018, Sajimol Francis did commendable work.

More than 500 fishermen were sent for more than a week to Alappuzha, Chengannur, Ernakulam, and Aluva – the worst affected areas – on 50–60 boats for rescuing and rehabilitating the victims. Then, as the whole world noticed, fishermen/women became Kerala’s new army. At great risks to their own lives, they reached food, clothes, and medicines to those who were severely affected. The rescue team work was heroic and exemplary. Children got their study materials which were destroyed by the flood waters. Under the leadership of Sajimol Francis, several flood relief camps were set up to provide temporary shelter for the affected people. About Kerala elected panchayat members, one can say: a true leader is the one who knows the way but also shows the way (Institute of Social Sciences, Outstanding Women Panchayat Leaders Award, 2019).

According to Joy Elamon, director general, Kerala Institute of Local Administration: “These local bodies have given space for civil society in Covid management. That is what we see in panchayat level war rooms, call centres and domiciliary care centres. Volunteers along with the people’s representatives, panchayat staff and ASHA workers have made the Covid fight a mass movement” (Sabrang, *ibid.*).

Conclusion

Let me conclude quoting the Reserve Bank of India lauding Kerala’s Covid-19 containment strategy, attributing the success to empowered local governments and a robust healthcare system: “Kerala’s 1200 strong LSGs worked in tandem with the

State government to create effective interventions during the Covid-19 crisis. Intensive contact tracing and case isolation followed by the LSGs succeeded in containing large scale community transmission of the infection” (Covid Fight: RBI Praises Kerala’s Health Sector: Local Self-governments, 2020).

The panchayats were instrumental in spreading awareness, implementation of quarantine and lockdown guidelines, and reaching essential services to people under quarantine.

Abstract

Since long, animals have been brutally lost to disasters despite their owners' best effort to save them. There is a great emotional as well as an economic bond between humans and animals. The State has so far not made animals partners in disaster management plans. This chapter attempts to discuss and extensively survey the cattle losses in disasters and their impact upon human lives and national economy of the country. However, the argument made to express and establish animals as sentient being and attributing "legal personhood" to them may go a long way to sharpen human understanding of animals and an equal amount of attention to them as well during tough times.

National Disaster Management Authority, New Delhi, India

Introduction

Animals have been ignored in disaster management policies all across the world till recently, when many powerful authors (Beaudry 2019, Singer 1993, Skopek 2014) and judicial pronouncements (Courts across the world, i.e., Cecilia's 1916, Sierra's 1972 cases) advocated their sentient existence within a world dominated by humans. More recently, Narayan Dutt Bhatt's Uttarakhand High Court¹ (July 2018) case and Karnail Singh's Punjab & Haryana High Court² (May 2019) case recognized that animals breathe and need food, water, shelter, care, and medical attention like humans with whom they also share emotions. So, there is no reason to ignore them in disaster management policies. It is logical, ethical, and legal to give their due to animals when they get washed off in floods, get buried in landslides, and starve for basic needs when trapped in droughts, hurricanes, and fire without a bit of guilt in human-dominated rescue operations. When animals contribute a substantial share in generating resources consumed by humans, these resources should logically also be spent to protect them from many of these calamities. This has been recognized by Courts as falling within the State's moral and legal duty under doctrine of *parens patriae* (the power of the state to act as guardian for those who are unable to care for themselves, which includes children, disabled, etc.). This chapter focuses on cattle only, as author has a long experience in the National Disaster Response Force (NDRF) in India and neighborhood countries, with available authentic data but the argument is applicable equally on other animals as well.

Disasters and Cattle Losses

Natural disaster literature has ignored legitimate concerns for animals, and so neither in law nor in a structure of mitigation has this featured as a policy priority. This has devastated agrarian economy due to lack of a strategy to protect rare and expensive support system of rural households in the form of cattle, horses, sheep, goats, and poultry from floods, landslides, and drought. Agrarian economy is a pleasant blend of animals and crops which form an integral part of more than 70 percent of rural households. India has a large and thriving animal sector contributing around 5% to the GDP. It is blessed with the largest population of cattle and is the largest producer of milk in the world. The value of milk produced alone is more than wheat, rice, oilseeds, and pulses combined.³ For rural population in our country, animals are

¹ Narayan Dutt Bhatt's Uttarakhand Case 2018

² Karnail Singh & Ors vs State Of Haryana on 31 May, 2019, CRR-533-2013

³ Dairy is the single largest agricultural commodity contributing 5% of the national economy and employing more than 8 crore farmers directly. India is ranked first in milk production contributing 23% of global milk production. Milk production in the country has grown at a compound annual growth rate of about 6.2% to reach 209.96 million tons in 2020–2021. Based on data taken from the National Dairy Development Board and DAHD:p.277, Economic Survey 2021–2022. Available at https://www.indiabudget.gov.in/economicsurvey/ebook_es2022/files/basic-html/page277.html

sources of economic well-being, food, security, and companionship, and more importantly they promote generation of wealth. Even during disasters when crops are destroyed, farmers having some highland manage to subsist through livestock. A recent study showed that farmer suicide was less among those who had livestock. Therefore, the challenging task for achieving Sustainable Development Goals (2015–2030) is to protect our livestock through proactive mitigation and capacity building measures with regional and global cooperation.

Indigenous animal breeds have inherent resistance to diseases and withstand diverse climatic conditions. However, despite this embedded strength and growth potential in the Indian animal husbandry sector, there are serious roadblocks to growth in the form of recurrent floods, droughts, and other man-made calamities. In short, lack of a streamlined institutional policy that absorbs shocks from nature and man-made disasters has been generating disaster-triggered poverty in agrarian lives. The flood guidelines of NDMA⁴ reveal that more than 94,830 animals perish every year in just one disaster “floods” every year repeatedly. This is in itself a shocking number and enough to sink rural households in abject poverty, yet if losses and impact on account of other disasters on animals are added to this number, then the developmental efforts in rural areas may appear meaningless. Disaster officials while going through the rescue operations in villages have found equally significant number of other milch animals but which do not get reported or highlighted by the media. Earthquakes, floods, landslides, cyclone, tsunamis, droughts, wild fires, etc. play havoc with human and livestock population. These challenges are increasing manifold with environmental threats which our planet faces today.

Disaster management (DM) is designed to protect, conserve, and safeguard livestock and other animal wealth through preemptive and proactive mitigation measures through regional as well as international support measures. In this context Bangladesh, India, and Nepal as well as Bhutan have entered bilateral animal protection agreements. These agreements rarely become any priority in implementation. Recently, India and Bangladesh signed seven agreements but entered only one on animals and that too for transborder elephant conservation but none on what has become an unending battle between the two nations, that is, cattle in cross-border floods. This neglect also prevents treatment of cattle during cross-border epidemics like lumpy skin disease or foot and mouth diseases.

Animals in National Policy Framework

Article 48A of the Directive Principles of State Policy in Chap. III of the Indian Constitution and in the National Policy on Disaster Management has brought out animal concerns in disaster management with specific recommendations. This becomes important to formulate a policy of preparedness for animals in disasters.

⁴National Disaster Management Authority (NDMA) Flood Guidelines, Government of India, available on <https://ndma.gov.in/Natural-Hazards/Floods>

The Department of Animal Husbandry and Dairying (government of India) has also prepared a disaster management plan which lays down how to protect animals before, during, and after disasters. Significantly, India is the first country in the world to have prepared its national plan on management of animals in emergencies way back in 2016.

In the context of contemporary developments, this issue of management of animals in disasters has assumed greater significance in the wake of emphasis given on livelihood protection in the “Sendai Framework of Disaster Risk Reduction” (SFDRR), 2015–2030. SFDRR, while delineating a clear commitment to the protection of livelihoods, has significantly highlighted the connection of livelihood to productive assets which for a rural terrain are livestock, working animals, tools, and seeds.

Another significant development in this context is the landmark judgment of Uttarakhand High Court on 4th July, 2018,⁵ on protection and welfare of animals. The high court stated that the animal and plant kingdom are one, and in declaring it as such, the apex court relied on the supreme court verdict in Animal Welfare Board vs A. Nagaraja and others.⁶ “The entire animal kingdom, including avian and aquatic animals are hereby declared ‘Legal entities’, having corresponding rights, duties and liabilities of a living person” (Uttarakhand High Court 2018).

The vision enshrined in the National Policy, SFDRR, and Uttarakhand High Court verdict relating to animal welfare calls for legislative support for effective implementation. However, in the Disaster Management Act, 2005, which is otherwise a very well-drafted act, there is no specific mention of animals. This act provides for a three-tier institutional mechanism at national, state, and district levels for implementation of its provisions. But there is no role assigned to the Department of Animal Husbandry. This is a serious gap which needs to be addressed by including appropriate provision relating to management of animals in disaster in the act. It is high time that a much awaited holistic vision that accommodates SDGs’ developmental strategies with commitments to the Sendai Declaration on disaster risk reduction may accelerate sustainable development in disaster-affected villages.

In this backdrop, the India chapter of World Society of Animal Protection (WSAP, now known as World Animal Protection, WAP) conducted an exercise in 2012 to identify the gaps in the field of management of animals in emergencies. This exercise identified the following major gaps:

- Inadequate trained human resources
- Inadequate training infrastructure and facilities
- Department of Animal Husbandry not integrated in the disaster management framework

⁵Narayan Dutt Bhatt vs Union Of India And Others on 4th July, 2018, Writ Petition (PIL) No. 43 of 2014.

⁶Animal Welfare Board vs A Nagaraja and others. SC CIVIL APPEAL NO. 5387 OF 2014, SLP (Civil)No.11686 of 2007.

- Absence of national-, state-, and district-level disaster management plans for management of animals in emergencies
- Lack of awareness among farmers and other stakeholders
- Lack of involvement of knowledge institutions

Role of NDMA in Promoting Animal Welfare

Taking cognizance of this report, the NDMA held a series of meetings with WSAP in 2012–2013, and the following decisions were taken to fill the gaps in the field of management of animals in emergencies:

- To establish Veterinary Emergency Response Units (VERU) in veterinary universities and colleges to impart knowledge and skills to veterinary students on this issue and also to initiate steps for awareness generation among farmers, etc.;
- To train personnel of National Disaster Response Force (NDRF) for swift rescue operations of animals during disasters
- To develop training modules for the National Institute of Disaster Management (NIDM) for capacity building of stakeholders in this field, as per its mandate
- To initiate other steps for effective management of animals in emergencies

In pursuance of above decisions, six centers of VERU were established in the veterinary universities/colleges at Patna, Chennai, Guwahati, Jabalpur, Palampur (HP), and Anand (Gujarat) by NDMA in association with WSAP and state authorities. These VERUs in the states act as regional training centers/center of excellence with the primary task to deliver trainings on animal-specific issues related to disaster management for the veterinary students, para-veterinarians, farmers, communities, and other relevant stakeholders. The VERUs carry specific value addition within the veterinary fraternity for effectively bringing resiliency of the vulnerable communities in the states. VERUs have been established as an integral part of the disaster risk reduction program in the respective states which needs to be emulated by other states as well.

As far as training of responders is concerned, around 300 NDRF personnel have undergone Training of Trainers (ToT) programs organized at different VERUs by the Policy Perspectives Foundation (PPF) in association with World Animal Protection and state administrations. As a result of these trainings, the NDRF has rescued 14,178 animals till mid-2021. The personnel of Bihar State Disaster Response Force have also been trained. The training of responders should be an ongoing process with personnel of SDRF in other states also being trained in animal rescue operations. National Institute of Disaster Management (NIDM), which is mandated to take proactive initiative in organizing capacity building, should organize capacity building and awareness generation programs in this field for all stakeholders in association with State Disaster Management Authorities (SDMAs), training institutions in the states (ATIs), VERUs, and other veterinary institutions. For the success of this

initiative, involvement of Panchayati Raj Institutions (PRIs) would be very important.

Notwithstanding the fact that animal-related issues do not find any mention in the Disaster Management Act, 2005, nor is there any structured institutional mechanism mandated to deal with this subject, many states and veterinary institutions have taken commendable initiatives to deal with this subject. Examples of good initiatives in this field by some of the states and veterinary institutions are as follows.

Bihar is the first Indian state to develop a [Road Map on Disaster Risk Reduction in 2015](#) in line with the Sendai Framework of DRR. This document has an exclusive chapter on “resilient villages” which covers almost all issues dealing with management of animals in emergencies. Bihar is also the first state to establish a VERU center in Bihar Veterinary College to provide essential knowledge, skills, and hands-on training to veterinary students to support emergency needs of animals. The VERU center in Bihar has so far trained 568 veterinary students and 1180 veterinary officers, besides conducting 3 training programs for personnel of NDRF and SDRF and organizing 29 animal health camps and awareness programs to sensitize people of flood- and drought-affected areas.

In Assam, one of the most disaster-prone states, the various provisions relating to mainstreaming animal issues in disaster risk reduction have been included in the Assam Disaster Management Manual, 2015. Considering the fact that this issue is the primary responsibility of the Animal Husbandry and Veterinary Department, their role is identified in the manual. The roles are defined for phases like preparedness, prevention, mitigation, response, recovery, and rehabilitation. The Animal Husbandry (AHD) & Veterinary Council of India (VCI) and Veterinary Department (VD), Assam also has a departmental Disaster Management Plan in place. Other significant initiatives taken by Assam include formation of rapid response teams and introduction of “boat clinic” and mobile veterinary units with 24x7 call center system for door step veterinary services, etc.

Kerala has taken significant initiative in decentralizing disaster management with major responsibilities shifted to the local self-government (LG). The LG disaster management plan is inclusive of animal care. Among other initiatives, the state has gone for identifying potential temporary shelters and also having raised platforms as relief centers for animals at ward levels. The state has also gone for network of trained animal rescuers in fire and rescue departments, civil defense, Aapda Mitra, LG Emergency Response Teams, etc. It has also included animal care requirements in the State Disaster Response Reserve.

Since Rajasthan has scarcity of fodder, cattle camps and fodder depots are being managed by the state DM department in ten drought-affected districts. Rapid response teams have been constituted at district as well as block levels for any emergency situation. Veterinary mobile teams have been constituted with required resources like medicines, vaccines, mineral mixture, etc. to deal with any drought situation. Other significant initiatives include mass vaccination programs of animals in affected areas, identification of space for proper disposal of carcasses, promoting livestock insurance, etc.

In Tamil Nadu, the first VERU in south zone was set up at Madras Veterinary College, Chennai, in 2013. Subsequently VERUs have been established at three other veterinary colleges in the state. Each VERU has a coordinator, two co-coordinators, and four faculty members. These VERUs regularly organize block courses which have three components: knowledge-based trading, skill-based activities, and simulation exercises/mock drills. In association with Tamil Nadu Veterinary and Animal Sciences University (TANUVAS), the Madras Veterinary College has prepared a *Handbook on Management of Animals in Disaster* in 2020. It is a very comprehensive document covering animal handling, wildlife rescue, feeding strategies, disease control, animal shelters, carcass disposal, etc.

Drawbacks and Way Ahead in Absorbing Animal Welfare Policies

As far as these initiatives are concerned, the states are working in silos without any mechanism of sharing of experiences or best practices with other states. Since issues related to management of animals during disasters is important, this needs appropriate institutional coordination and an infrastructure that caters to support varieties of rural animals. Concerns for poverty reduction and food security should work on one platform. Keeping this aim in mind, many nongovernment organizations including Policy Perspectives Foundation and Sphere India organized a national-level workshop under the aegis of Ministry of Animal Husbandry, National Disaster Management Authority (NDMA), and Veterinary Council of India in New Delhi on 22nd of June, 2022. All these ground-level community organizations unanimously agreed to achieve such a framework for action on rural animals and livestock populations trapped in recurrent disasters.

The objective of this workshop was to deliberate on measures to institutionalize animal-related issues in disaster management framework and formulate an appropriate framework of coordination for multi-stakeholders in the field. It also envisaged furthering the initiative to establish Veterinary Emergency Response Units (VERUs) in veterinary universities to impart knowledge and skill to veterinary students, veterinarians, and other stakeholders and capacity building of responders (NDRF, SDRF, etc.) for swift rescue of animals in disasters, besides generating awareness among stakeholders on management of animals in emergencies. The significant feature of these deliberations was high-level participation of key agencies of the government of India, namely, Ministry of AHD, NDMA, and VCI, besides experience sharing by four states (Assam, Kerala, Rajasthan, and UP) and NDRF and presentations by two premier veterinary institutions, namely, Tamil Nadu Veterinary and Animal Sciences University (TANUVAS) and Bihar Veterinary College. The workshop was conducted in hybrid mode.

Referring to a very clear economic rationale to invest in animal protection, the deliberations in this workshop highlighted that strengthening animal protection during disasters would need various measures like laws, regulatory framework, community-based approach, integration of planning process and SOPs in state and district DM plans, capacity building of veterinarians and responders besides

investment in wildlife protection, etc. Some of the key recommendations of this workshop include the following:

- Amending the Disaster Management Act, 2005 to include Animals in DM framework and also to include Secretary, Animal Husbandry in the National Executive Committee
- Promoting training and capacity building on management of animals in emergencies to key stakeholders like veterinarians, para-vets, SDRF, etc. to generate more human resources in this field
- Adopting a community-based approach toward animal protection in disasters by training community representatives, PRIs, "Aapda Mitras," etc.
- Encouraging ex-servicemen from veterinary corps to register themselves with District Disaster Management Authorities to be force multiplier
- Proposing amendment by all the veterinary universities and colleges to Minimum Standards of Veterinary Education (MSVE), 2016, with dedicated chapters on disaster management, DRR, and the challenges relating to disaster management with regard to animals in consultation with VCI
- Establishing more Veterinary Emergency Response Units (VERUs) in veterinary universities and colleges
- Establishing National Digital Animal Health Mission on the lines of National Health Mission to prioritize animal protection
- Furthering the initiative of AHD relating to census of livestock by tagging of animals
- Increasing investment and efforts toward integration of animal protection in disaster management policy and programmatic framework
- Ensuring effective multi-sectoral coordination between Department of Animal Husbandry at center and states, SDMAs, NDRF, and veterinary institutes for disaster preparedness, response, and rescue of animals

Since the key agencies dealing with this issue at the national level, namely, Department of Animal Husbandry, NDMA, and Veterinary Council of India, have been involved in this workshop, hopefully these recommendations will pave way for appropriate amendments in the Disaster Management Act, to include animal care and protection into national, state, and district disaster management plans, inclusion of animal-related issues in the disaster management framework in the country, and an action plan for capacity building of all stakeholders in this field.

Conclusion

Animals deserve attention in disaster management policies from a moral, ethical, and legal reasoning. Economically also the State may not be able to bear the loss of many of these animals. The key agencies dealing with this issue at the national level, namely, Department of Animal Husbandry, NDMA, and Veterinary Council of India, have been involved in deliberations to make a strong case for their inclusion in the

mainstream disaster management policy. Many of their recommendations have already paved the way for appropriate amendments in the Disaster Management Act, to include animal care and protection into national, state, and district Disaster Management Plans, inclusion of animal-related issues in the disaster management framework in the country and an action plan for capacity building of all stakeholders in this field. The future can be made brighter for animals trapped in disasters with certain changes in ground level functioning of governance agencies.

Abstract

Odisha is frequently affected by cyclonic storms of various intensities due to its location on the eastern coast of India. In the recent past, very severe cyclonic storm (VSCS) like super cyclone ravaged the state. The state govt. initiated various management practices to lessen the impact of such natural calamities. In this chapter, an attempt has been made to study the management of impact of the most recent tropical cyclonic storm Fani that hit the Odisha coast. Fani hit the Odisha coast near Puri, a coastal town of Odisha on May 3, 2019, at 8:30 A.M. Due to its impact, 14 coastal and adjoining districts were affected with heavy rainfall and wind speed up to 175 kmph. The most severely affected districts were Puri and Khordha. The state govt. took necessary steps to disseminate cyclone warnings received from the India Meteorological Department (IMD) to the likely affected districts before Fani could strike the state in order to reduce the loss of life and property. Necessary preparations were made by

sending manpower, machine, and relief materials to the districts. As preventive measures, people living in vulnerable areas and livestock were evacuated to the cyclone/flood shelters with necessary arrangements; all kinds of transports were suspended, holiday was declared for the education institutions, and leave of the employees was cancelled. For emergency communication, district collectors were provided satellite-based phones. Due to well-planned measures, human casualty could be minimized. Most of the damages occurred to temporary houses, power transmission line, telecommunication, agriculture, horticulture, livestock, infrastructure, and natural vegetation. Rescue and relief operation started immediately in the affected areas. State govt. provided compensation and subsidy to the affected people on the basis of the state relief code. Steps were taken to restore normalcy on war footing. Damages due to Fani caused heavy economic loss to the state.

Preparedness · Response · Warning · Evacuation · Compensation

Introduction

Human sufferings have increased in recent years due to increasing frequency and magnitude of natural and man-made disasters in the world (Akter & Wamba, 2017; Mavhura, 2015). Human lives, properties, and infrastructures are severely affected by these disasters. About 75,000 people were killed and 200 million people affected. The annual economic loss in the last decade due to natural disasters was about 162.2 billion USD and is likely to increase in the future (IFRC, 2015). The factors responsible for increasing disaster risks are global climate change, population growth, inadequate govt. preparedness at national and local level, weak legislation, and absence of disaster management institutions (Mukhtar, 2018; Rivera et al., 2020). Disaster risk can be reduced by adopting multisectoral, multidimensional, and community-based approach for disaster management (Ahmed, 2013). Adoption and implementation of comprehensive disaster management by the government is essential for successful disaster management by (1) government policy on disaster management; (2) enactment of laws for mandates, duties, and responsibilities of the stakeholders; and (3) institutional structures and policy for coordination of local governments and communities (Ishiwatari, 2013; UNISDR, 2015). Many nations of the world have enacted their own DM system, based on their experience, political system, cultures, legal contexts, availability of resources, vulnerability to disasters, and past experiences (GoI, 2013).

Climate of the Earth is changing from its inception, but the recent climate change is adversely affecting the living community (IPCC, 2013; Solomon et al., 2007). Natural disasters (severe cyclonic storm [SCS], flood, drought, etc.) are increasing intensity and frequency due to climate change adversely affecting socioeconomic development and the living communities (Azam et al., 2019).

Tropical cyclones and other weather-related disasters account for 91% of all natural disasters that occurred between 1998 and 2017 in the world (Arrieta et al., 2009). Most of the deaths are due to geophysical disasters, whereas most of the economic loss are due to climate-related disasters. In the period 1998–2007 about 2,245 billion US dollars (or 77% of the total) loss in the world due to geophysical disasters, out of which 59% are due to storms. As most of the disaster losses were not reported, the loss could be much more. Only 13% of climate-related disasters were reported in the developing countries. The 2005 (Wilma, Rita, and Katrina) or 2017 (Maria, Irma, and Harvey) hurricane resulted in economic loss of 245 and 201 billion US dollars, respectively. It shows huge losses due to cyclonic events. With the global climate change, the situation will further deteriorate as the precipitation pattern in the tropical region will be more extreme leading to flooding in association with sea level rise (Berke et al., 1993; CEOS, 2002; Chang & Miles, 2004; Chittibabu et al., 2004; Badola & Hussain, 2005; Chamlee-Wright & Storr, 2011; Chhotray & Few, 2012; Berrang-Ford et al., 2015; Anthes, 2016). On the basis of the above observations, global initiatives are taken for preparedness and prevention to minimize loss under the Sendai Framework for Disaster Risk Reduction 2015–2030, Agenda for Sustainable Development of 2030, the Paris Agreement, and the Addis Ababa Action Agenda (Collins, 2009; Das, 2005; Cretney, 2017; UNDRR 2018). Under the Sendai Framework, it is planned to reduce economic loss, mortality, disruption of basic services, and damages of critical infrastructure by 2030 (Collins, 2009). For long-term recovery from disasters, planning has been made to change from post-disaster response to pre-disaster prevention and preparedness (Collins, 2009). Disaster risk can be reduced based on the assessment of the recovery capability (Dash et al., 2004; Das & Crépin, 2013). For recovery from disaster, it is necessary to understand, identify, and assess essential conditions (Debarati & Below, n.d.; DeSalvo et al., 2007; Das & Crépin, 2013). Recovery rates from disaster depend on environmental, infrastructural, and socioeconomic conditions in different disasters lead to different recovery rates (Das & Crépin, 2013). As not much studied about recovery rate from disaster, it may be quick or delay (Gray, 1968; GoO, 1999; Das & Crépin, 2013). Maximum people were killed and affected leading to economic loss due to natural disasters. Asia is a leading disaster-prone region of the world, especially hydrometeorological disasters like tropical cyclones, which result in maximum loss of life and property (ADRC, 2014). In the assessment report of the intergovernmental panel on climate change, Working Group I (IPCC, 2013) observed that the number of tropical cyclones is not likely to increase, but wind speed and precipitation will increase. Due to the impact of severe tropical cyclones, some coastal regions are severely damaged. In terms of the cyclonic storms, the Bay of Bengal is ranked sixth in the world (Iwasaki et al., 2009). The region experienced 26 severe tropical cyclonic storms out of 36 that occurred in the world (Weather underground, 2015).

Usually tropical cyclones develop in the post-monsoon season in the month of October and November in the Bay of Bengal (OSDMA, 2016). Due to the impact of

climate change, the sea surface temperature increases leading to increasing intensity of tropical cyclones in the Bay of Bengal.

Due to disasters, India lost about 79.5 billion dollars between 1998 and 2017. India is one of the top ten countries of the world in terms of loss due to disasters (Arrieta et al., 2009). Among the coastal states of India, Odisha is highly vulnerable to tropical cyclones. Most of the cyclones developed over the Bay of Bengal hit the Odisha coast in the past. In terms of the number of land fall of the tropical cyclones along the Indian coast, the Odisha coast hit by maximum number (29%), West Bengal coast (14%), Andhra Pradesh coast (13%) and Tamil Nadu coast (7%). The Odisha coast is hit by severe cyclonic storm every 4 years and West Bengal coast every 5 years. The revisit period for cyclones to the Odisha coast is 2 years much shorter than other states (Memorandum Fani 2019). The super cyclone of October 29, 1999, with wind speed of 270 to 300 kmph made a landfall at Paradeep in the Odisha coast which was the most intense tropical cyclone developed over the North Indian Ocean.

Odisha with its 480 km long coastline along the Bay of Bengal is the eastern coastal state of India (Fig. 1). The state has 30 districts, of which 6 coastal and 8 adjoining districts are cyclone prone (Mohapatra et al. 2011). Balasore and Bhadrak districts are the most vulnerable districts of the state. These 14 coastal and adjoining districts have a population of 24,862,273 (59.23% of the total population), and the six coastal districts have a population of 13,883,624 (33.07%). Most of the people of the state live in rural areas, and agriculture is their main source of

Fig. 1 Location of the study area – Odisha state

livelihood. More than 75% of people depend on agriculture, and most people live in semipermanent and temporary houses not resilient to cyclone and flood. In rural areas, 66.73% of people and in urban areas 41.58% of people live in such type of houses.

After super cyclone of 1999, Odisha became the first state in India to develop disaster risk management structure. The Odisha State Disaster Management Authority (OSDMA) was formed under the provision of Disaster Management Act, 2005, in the Department of Revenue. The state developed disaster mitigation strategies by huge investment in multipurpose cyclone and flood shelters (OSDMA, 2016).

Extremely Severe Cyclonic Storm (ESCS) Fani

The name "**Fani**" has been chosen from the list of names created by South Asian countries. The name was picked by Bangladesh. Fani is different from other cyclones due to its intensity and took a long time to travel over the sea. After its origin near the equator, it travelled a long distance over the Bay of Bengal and gathered massive strength and moisture. Fani is classified as an extremely severe cyclone (ESC) on the basis of its wind speed. In the last 52 years, Fani is the tenth such cyclone that hit the Indian coast in the month of May. In 2004, such type of cyclone hit the Indian coast in the month of May. In the post-monsoon season (October to December), the east coast of India is normally hit by extremely severe cyclones. IMD has classified the cyclones into five types on the basis of wind speed: cyclonic storm (CS) with a maximum wind speed of 62–88 kmph, severe cyclonic storm (SCS) with a maximum wind speed of 8–119 kmph, very severe cyclonic storm (VSCS) with a maximum wind speed of 119–165 kmph, extremely severe cyclonic storm (ESCS) with a maximum wind speed of 166–220 kmph, and super cyclone (Sup CS) with a maximum wind speed of 221 kmph and more. IMD forecasted on April 21, 2019, the condition ideal for the formation of low pressure in the equatorial Indian Ocean and south Bay of Bengal. The cyclone Fani meandered over the Bay of Bengal for a long time and changed its track many times over the sea. IMD had to revise its forecast nine times before landfall in the Odisha coast. Fani made a landfall in the morning of May 3, 2019 instead of evening or late night as predicted by IMD. After super cyclone of 1999, Fani is the second strongest cyclone that passed over Odisha. After 1976, cyclone Fani passed over India in the month of April. In comparison to the recent past severe cyclonic storm "Titli" and "Phailin," it is more severe. Fani, an extremely severe cyclonic storm (ESCS), made a landfall between Satapada and Puri at 8:30 A.M. with wind speed of 205 kmph and tidal surge of 1.5 meters. It made a landfall in the morning against evening or late night with wind speed of 170–180 kmph predicted by IMD. After the landfall, it continued with same intensity for 6 hours and moved in north-northeastward and entered Khordha district around Bhubaneswar. It passed over Cuttack, Jagatsinghpur, Kendrapara, Jajpur, Bhadrak, Balasore, and Mayurbhanj districts of Odisha and emerged into Gangetic West Bengal as a severe cyclonic storm (SCS) (Fig. 2).

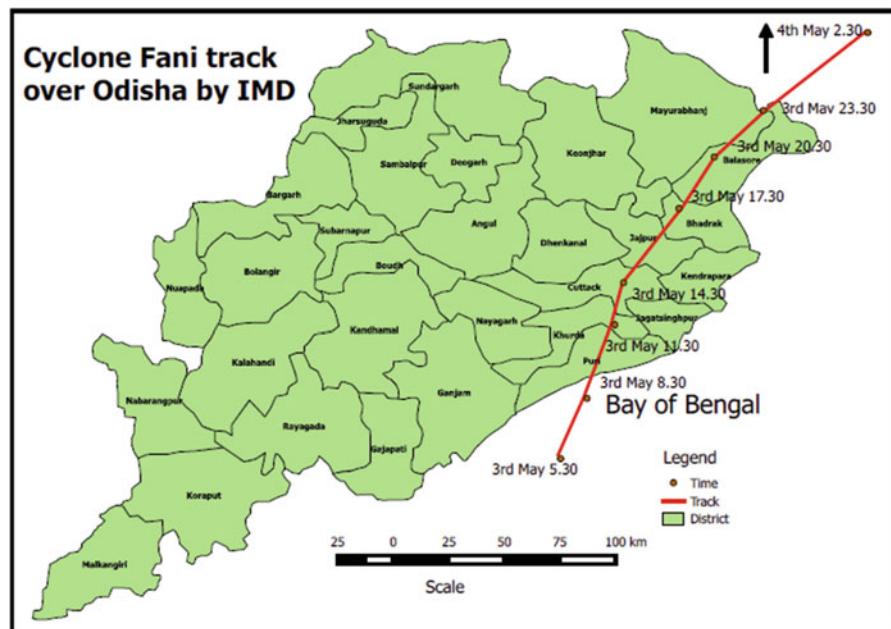

Fig. 2 Track of Fani by IMD

Impacts of Cyclone Fani

Fani hits the coastal Odisha on May 3, 2019, with devastating wind speed, heavy rainfall, and storm surge. Due to the impacts of strong wind and heavy rainfall, thatched houses, trees, power, telecommunication, roads, railways, crops and irrigation systems, and livestock were affected. The affected districts received rainfall of 100–300 mm on May 3 and 4. Khordha district received a maximum rainfall of 187.8 mm, and Angul district received a minimum rainfall of 49.2 mm. 20367 villages were affected. A maximum of 2673 villages in Ganjam district and a minimum of 67 villages in Angul district were affected. About 159 C.D. blocks and 51 urban local bodies were affected. A maximum of 12 urban local bodies were affected in Ganjam district. Total houses damaged were 679155 with a maximum of 323140 houses damaged in Puri district and a minimum of 519 houses damaged in Angul district. About 15993851 people were affected in 14 districts which are about 36% of the population of the state. A maximum of 2502008 people were affected in Khordha district, and a minimum of 5709 people were affected in Angul district. Human casualty minimized through preventive measures taken by the govt., for example, evacuation to cyclone shelters. Total human casualty was 64. A maximum of 39 people were killed in Puri district, the landfall point of Fani. The deaths were due to collapse of the houses and falling of the trees. About 5333186 livestock and poultry birds were killed with a maximum of 2671929 deaths in Puri district.

The total crop area damaged was 181711.4 hectares, with a maximum crop loss in Puri district of 60339 hectares. The total cost of damages of the state was Rs. 933627.23 lakh. Maximum cost of damages in energy department of Rs.115977 lakh and minimum in labor department of Rs.78 lakh. The vulnerability analysis of the state due to Fani has been analyzed, and it was found that out of the 14 affected districts, very highly vulnerable districts are Puri, Khordha, and Cuttack; highly vulnerable districts are Jajpur, Jagatsinghpur, Nayagarh, Balasore, and Ganjam; moderately vulnerable districts are Mayurbhanj, Bhadrak, Dhenkanal, and Kendrapara; and low vulnerable districts are Angul and Keonjhar. The vulnerability decreases with increasing distance from the coast and distance from the track of the cyclone Fani (Table 1 and Figs. 3, 4, and 5).

Preparedness, Prevention, and Mitigation

Fani was monitored on the basis of the forecast of India Meteorological Department (IMD), Joint Typhoon Warning Center (JTWC) of the USA, and Regional Integrated Multi-Hazard Early Warning Systems (RIMES) of Thailand. Massive preparedness was undertaken on receiving the cyclone warning from IMD. People of the likely affected districts were alerted about the cyclone to minimize the loss of life and property. District collectors of 14 coastal and adjoining districts were advised to identify vulnerable people living in temporary houses or living close to the coast or low-lying areas as part of the preventive measures. The vulnerable people will be shifted to the multipurpose cyclone/flood and other safer shelters (Fig. 6). Tourists were evacuated from the coastal districts. Steps were taken to provide safe drinking water, free kitchen, lighting, health, and sanitation facilities at the shelters. To streamline emergency services, control rooms of related departments were functioning on a 24-hour basis. Three hundred power boats of Special Relief Organization were kept ready with crew and fuel for emergency relief operation. To shelter evacuated people, 879 multipurpose cyclone/flood shelters of the Odisha State Disaster Management Authority (OSDMA) were kept ready. For proper preparedness at the shelter level, the district administration consulted with the Cyclone/Flood Shelter Management and Maintenance Committees (CSMMCs/FSMMCs). The volunteers of the shelter-level task force were used to assist the local community for evacuation and any emergency results due the cyclone. Another important step taken by the govt. for livestock protection during cyclones is the identification of 635 animal shelters as school premises and multipurpose cyclone shelters. In order to avoid livestock loss, field veterinarians were instructed to inform the dairy farmers and small animal owners to take necessary measures to shift their animals to safe places. To avoid spilling or leakage of hazardous materials in industries/factories, instructions were issued for safe storage of such materials. Very often matured crops are damaged due to cyclones and associated floods. In order to minimize crop loss of the farmers, district-level officers were advised to circulate agro-based crop advisory to the field functionaries and farmers prepared by Odisha University of Agriculture and

Table 1 Vulnerable districts of Odisha due to cyclone Fani

District	Population affected	Livestock and poultry affected	Number of villages affected	Rain fall in mm	People killed	Livestock killed	Houses damaged	Crop area affected in ha	Vulnerable index

Technology (OUAT) and Directorate of Agriculture on crop management during and before the cyclonic storm. Farmers were advised to harvest matured crops and keep them at a safe place to avoid crop damages. Urban floods occur due to incessant rain coupled with urban drainage congestion. To prevent urban flood and water logging, drains were cleared of blockages and de-silted for free flow of storm water. In order to drain out water logging in urban areas, high-capacity diesel pump sets were kept ready. The coastal wild life sanctuaries are normally affected due to cyclones, and wild animals enter into human habitation. Precautionary steps were taken to sensitize the villagers living in and around the Balukhand-Konark sanctuary area. For protection and rescue of wild animals in vulnerable areas, the forest department deployed special squads. Print, electronic and digital media played a proactive role in dissemination of information on cyclone path, predicted intensity, evacuation of people, encourage people to face the situation, spread of awareness, removal of rumor, post disaster real picture, mobilize, state, nation and international resources for better disaster management. Due to the impact of cyclones, people usually suffer from health problems like diarrhea due to drinking of contaminated water and snake bites. In order to prevent health problems, all emergency logistics (antibiotics, antipyretic, antidiarrheal, ORS, Halogen/chlorine tablets, anti-snake venom, IV fluids, etc.) in sufficient quantity were provided to all 14 districts likely to be affected by Odisha State Medical Corporation Limited (OSMCL). In case of any disaster, the highly vulnerable people are the elderly, differently abled persons, women, and children. Instructions are issued to take special care of women, elderly, differently abled persons, and children. For effective disaster management, meetings were conducted between govt. and NGOs for proper coordination at OSDMA office and in the districts. For timely response to the cyclone disaster, interdepartmental coordination meetings with the nodal officers were conducted regularly to assess the preparedness. State govt. requisitioned two helicopters from the Ministry of Defense, Govt. of India (GoI), for emergency rescue and air-dropping of relief materials. With the help of Odisha Rural Development and Marketing Society (ORMAS), Industrial Development Corporation (IDCO), and Food Supplies and Consumer Welfare Department, 100,000 food packets were prepared. All educational institutions (both private and government) were closed from May 2, 2019, and examinations were rescheduled as preventive measures. Senior IAS and IPS officers were given responsibility to extend all possible support to the district collectors of the districts likely to be severely affected. To provide relief to the marooned people, 5,97,006 numbers of polythene sheets were kept ready for distribution to the affected people. Due to cyclone, power and telecommunication were severely affected. Fifty-five satellite phones were provided to the likely affected districts, and response forces were kept ready for establishing emergency communication. To avoid loss of life, boat operation ferrying tourists in the Chilika Lake was prohibited. Keeping in view of the risk of life of the fishermen in the coastal areas, the govt. debarred them from fishing in the sea. The state govt. issued fishing ban from April 15 to May 14 as per the uniform fishing ban imposed for east coast of India by the Govt. of India (GoI). To avoid damages to the fishing boats by wave surge,

fishermen safely berth their fishing boats at a safer place in fishing harbors and fish landing centers. With the past experience of Odisha super cyclone of 1999, people suffered due to disruption of train, bus, and air services; therefore, to avoid repetition of such situation, the state govt. in advance suspended these services. Most vulnerable villages in the coastal area were identified using GIS platform based on forecasted track. The buffer area of 10km distance from the forecasted track on the landward side and entire area of the seaward side were taken as the severe impact areas. A total of 9886 villages and 52 towns of nine districts were identified as severe impact areas of the cyclone. On the basis of the severity of the impact of the cyclone, the collectors of the districts were asked to take preparedness measures. Twenty-eight teams of the National Disaster Response Force (NDRF) at strategic locations of 14 districts were kept ready with requisite equipment for immediate response (Fig. 7). Anticipating the severity of the event, the state govt. sent request to IG, NDRF, New Delhi, for deployment of additional 20 NDRF teams from the neighboring NDRF battalions. Fire services in all the districts were kept ready for immediate response. Personnel of Odisha Forest Development Corporation (OFDC) were kept ready to remove damaged trees blocking the road and rail communication. Drinking water sources were contaminated due to flood caused by heavy rainfall. Hence adequate arrangements were made for safe drinking water like water pouch, water storage in over head tank and pvc tanks. DG sets with fuel, electricians and other necessary requirements were kept ready for supply of drinking water.

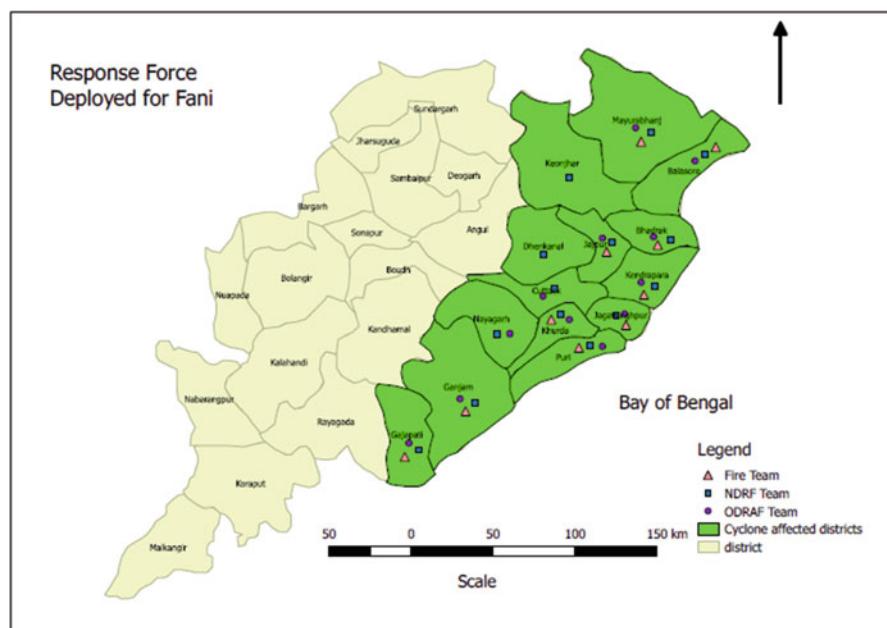

Fig. 7 Response forces deployed

Response and Relief

The state govt. as part of the response to the disaster alerted the people about the cyclone and precautionary measures to be taken through SMS and location-based alert system (LBAS). People of the likely affected districts were alerted through 1.8 crore SMS to BSNL subscribers. On the basis of threat of an area, group-based alert messages were sent. Voice messages were sent every hour in the coastal area, and Sirens installed at the coast were activated. In the district, warning was sent through official channels and PRI members. At the local level, public announcement was made to inform the people (Fig. 8). Fourteen satellite-based mobile data and voice terminals (SBMDVT) under early warning dissemination system (EWDS) were also activated for emergency communication. 15,57,170 people were evacuated in 14 districts from May 1, 2019, to May 2, 2019 (late night), before the cyclone could hit the coast. Much before the cyclone approached the state, the elderly, differently abled persons, women, and children were evacuated to the shelters on priority basis. From Puri, Ganjam, Cuttack, and Balasore districts, 24,889 tourists were evacuated. Livestock are the poor man's livelihood; earlier, no steps were taken for safety of the livestock from cyclones. Due to lack of protection, lakhs of livestock were killed. As preventive measures, 28.65 lakh cattle were accommodated in 6367 cattle camps and provided fodder/feed. Transport of relief materials to the affected people is a challenging task. Arrangements were made for free transport of relief materials by air and rail. For the smooth transport and distribution of relief materials, 23 trains, 18 OSRTC buses and other local transports were arranged. At the shelters, steps were

Fig. 8 Early warning, evacuation, cyclone shelter, and media report

taken to provide cooked food through free kitchen. Measures were taken to maintain sanitation at the shelters. Basic amenities like lighting and safe drinking water were provided at the shelters. The domesticated animals were shifted to the shelters with adequate fodder, drinking water, and medical care. Provisions were made for health care during the disaster by deploying health workers, doctors, and medicines. Steps were taken for the removal of carcass of dead animals to prevent spread of epidemics. In the severely affected districts, emergency communication was established using HAM radio, very high frequency (VHF) and satellite phones, and other traditional communication systems. To bring back normalcy in the affected area, restoration work started on war footings. District administration and concerned departments taken up the restoration work of road communication, electricity, drinking water supply, telecommunication, and other critical services. The response forces deployed in the affected area were immediately mobilized for search and rescue of the stranded people. People needing medical treatment were immediately shifted to the hospitals. In the past, due to lack of coordination between govt. and NGOs, problems were reported in the distribution of relief materials. Therefore, the GO-NGOs at state and district level were activated for smooth distribution of relief materials. Keeping in view of the needs of the affected people, the govt. decided to provide relief materials in shape of rice along with cash and polythene sheet for temporary shelter. The banking service was paralyzed due to failure of power and Internet service. Therefore, the beneficiaries were provided gratuitous relief in cash with due approval of the Government of India. Families under food security were given 50 kg of rice plus Rs. 2000 and polythene, and families not covered under food security were provided 50 kg of rice plus Rs. 2000. Health services were restored, and fodder was provided for the livestock.

Recovery and Reconstruction

Recovery and reconstruction is a challenging task before the government. Most of the people in coastal Odisha depend on agriculture and live in temporary houses due to low economic status. Their livelihood and houses are easily damaged due to cyclonic storm and associated floods. As the frequency of the cyclonic storms is increasing day by day in the recent past, people are panic-stricken hearing the imminent cyclonic storm. Frequent cyclonic storms have broken their economy. In coastal Odisha, in addition to agriculture, people do livestock farming, horticulture particularly coconut farming, betel vine farming, and fish farming. The livelihood of the people depending on agriculture and related primary activities are severely affected. To bring back normalcy and pre-disaster situation, a lot of investment is required. As per the relief code, affected people were provided compensation based on the extent of damages. Compensation provided for the reparation of damaged houses Rs.2100 – 95,100, crop damages and input subside per hectare Rs.6800–18000, livestock loss with limited compensation Rs.3000–30,000, loss of poultry Rs 50 per bird to maximum Rs.5000. Compensation was given for the loss of fish ponds, fishing equipments, handicraft industries and street vendors. Exemption of

Fig. 9 Relief distribution, restoration work, and visit of the central team

school fee and supply of one pair of school uniform was done. Short-term loans for kharif and rabi crops were sanctioned to the affected farmers. Land revenue and water tax were exempted for the year 2019–2020. A 5-year action plan has been taken up by the govt. for the revival of shelter belt and afforestation. 50 lakh seedlings were distributed free of cost to the public and institutions. 30,000 uprooted but surviving trees were restored on war footing. The banking sector was affected due to Fani; steps were taken to normalize banking sector, and mobile ATMs were put into service. Steps were taken for the removal of debris, flood water, and disposal of carcass. The damaged infrastructure, road, river and canal embankments, water supply, power transmission system, and public buildings were repaired on emergency basis. Pensioners were given 1 month pension extra in severely affected district as relief. The central team visited the affected areas to take stock of the situation to recommend for central govt. assistance (Fig. 9).

Conclusion

The National Disaster Management Act 2005 enacted by the Government of India in order to mitigate the impact of the disaster in the country is a paradigm shift in the management of disaster. Fani occurred in pre-monsoon season which is a rare incident. Its prediction was most difficult as it went on changing its course nine times and hit the Odisha coast 6 hours before prediction. It was the most destructive cyclone after the 1999 super cyclone. It severely affected three coastal and adjoining districts with heavy damages. The loss of life and property was next to the 1999 super cyclone. The state govt. made all necessary arrangements after getting the

cyclone warning from the IMD. The cyclone warning was communicated to the people, and high-level meeting at state headquarters and district headquarters was conducted for smooth organization of Fani disaster management. Man and machine were sent to the field. Relief, medicine, and health workers were deployed to provide immediate service to the affected people. Cyclone/flood shelters were kept ready with all necessary facilities for people and livestock. Evacuation of people and livestock started before Fani could make a landfall, thus reducing human and livestock casualty. As a preventive measure, road, railway, and air communications were suspended to reduce hardship and casualty. Due to maximum damages in power transmission system, restoration of power and water supply was delayed. Unlike the super cyclone of 1999, people volunteered for evacuation and did not want to take any risk. Huge loss of property occurred in the capital city Bhubaneswar and coastal city Puri. Steps are being taken for underground power cabling to reduce damage to power sector. Loss of life could be minimized, but loss of property and livelihood is still very high. Efforts were made by the govt. to bring back normalcy by providing ex-gratia payment to the kin of the deceased, compensation for the loss of crop, livestock, houses, handicrafts and street vendors as per the relief code. To reduce damages of rural and urban temporary houses, state- and central govt.-sponsored housing schemes are being implemented for the poor people. Steps must be taken for disaster resilient power and infrastructure as part of the long-term solution to the cyclonic disasters. The disaster management of the state govt. was very successful. The state govt. got appreciations for successfully handling the cyclone Fani from the United Nations in India, Regional Integrated Multi-Hazard Early Warning System Programme Unit in Thailand, and Nanjing Autonomous Institute of Water Conservation and Hydrology in China.

Abstract

Indo-Nepal Tarai region is well-known for recurring disasters like flood, cyclone, earthquake, drought, and landslide. They have been affecting the people of this region almost every year. Regular occurring of disasters increases the social, economic, physical, and psychological vulnerability of the population. SAARC called for attention the condition of Indo-Tarai region and declared it a matter of human concern. It urges for initiatives on the preservation on the environment and disaster risk preparedness and response in the region. In addition, several

international, national, and regional NGOs and Government Agencies such as UNDRR (United Nation Office for Disaster Risk Reduction), CARE International, National Disaster Management Authority (NDMA) India, National Centre for Disaster Management (NCDM) Nepal, Rapid Response NGO (India), GNK (Gram Niyojan Kendra) India, Manav Seva Sansthan SEVA and DEHAT (Developmental Association for Human Advancement), India are playing important roles in disaster response, mitigation, and spreading awareness. But disaster response in the region is facing continuously challenges like absence of vertical and horizontal coordination between public and private organizations and organizations working across the border. It is worth mentioning that disasters do not consider political boundaries, and disaster-prone transboundary basin like Indo-Nepal Tarai region needs a strong international strategy and commitment for transboundary institutional cooperation's, which is generally absent in the region. Though the International and National organizations are usually following a common disaster management strategy, most of the time they remain unaware and insensitive toward the local requirements. These constraints often triggered disaster-related risks. Institutions are key players in developing policies and tools for disaster management. The focus of this study is to observe and assess the coordinated and uncoordinated responses of these institutions and existing international transboundary cooperation framework to achieve the objectives of reducing risks and vulnerabilities.

Keywords

Institutional response · Transboundary cooperation · Disaster management · Vulnerabilities

Introduction

Natural hazards are physical phenomena of nature, which is generally unpredictable and recurrent in nature; to manage them a well-structured and integrated frameworks and policies and combined efforts of local groups, national, and international level organizations and authorities are required. Disaster management is a continues process. It is mainly the responsibility of the government to play an important role by forming a favorable authority and setting up norms in the sector of disaster management. It is the government's duty to work as a defense and take care of the well-being of people. It has been noted the resources that are being used in the recovery process in the aftermath of a natural hazard are sometimes much more than required in the precautionary measures that can avert the disasters from happening. But it is also a fact that in any stage of disaster management, it may not be possible for government to reach out to each and every citizen of the country. At this point comes the role of nonprofit organizations. NGOs play a secondary role but a very significant one and are capable of helping the government in various matters. NGOs generally try to make sure that people's voices reach the policy makers. They praise

and also disapprove government's policies when it is required. NGOs play a very special role in the disaster management sector since they work very profoundly in local and global disaster risk management, climate-related adaptation and in humanitarian assistance (Lassa, 2018). But when a region falls under the political boundaries of different countries and most of the time get affected by natural and human-induced disasters, a cooperative effort in disaster mitigation and recovery is needed.

Therefore, the foremost objective of this study is to trace the role of institutions and organizations, which are actively working in the sector of disaster risk mitigation or disaster preparedness in Indo-Nepal Tarai region. The difference between government and nongovernment organizations response, the situation of vertical and horizontal coordination between various organizations, the core idea and purpose of the institutions and from where they are collecting the funds and how they are managing it are also some key areas to study. This study also tries to identify the critical issues that create hurdles in the smooth functioning of the institutional engagement in disaster management for plummeting the possible impact from future disasters.

Case Study: Area and Methodology

Indo Nepal Tarai region is Situated on the border of two converging tectonic plates and experience trans influencing climatic conditions therefore, the region is highly susceptible to geophysical and hydrometeorological disasters.

This research is about the Tarai region of Nepal and the bordering regions of Indian States: Uttar Pradesh, Bihar, and Uttarakhand; these areas have grown with diverse structure of governance and state devises for managing disasters risks.

According to the Human Development Index 2022, India is at the 132nd and Nepal is at the 143rd position in the list of 191 nations. Nepal comes under the category of low human development and India is categorized as medium development nation. It is crucial to understand that India has significant interstate disparity. On the basis of its multidimensional poverty index, it is found that more than half of the population of these border regions of Indian states live below the national poverty line and share similar socioeconomic characteristics. The region spread in both countries is mainly rural. There is a significant undersupply of public goods in the region such as electrical energy, water and healthcare, and other development activities. However, these civic amenities are well supplied in urban areas. Furthermore, caste and ethnicity based social inequality is very high across the borders in these regions. Like the rest of South Asia, the region has had uneven experience with decentralization.

The empirical data collection for this research was undertaken by a semi-structured questionnaire, which was mailed to representatives of different organization in March 2021 after a telephonic conversation. The questionnaires were intended to explore the institutional response for DRR, the role of different stakeholders, cooperation between two nations and the aspects that allow or hinder disaster risk reduction in the region. The questionnaires were sent to representatives

of international organizations, government bodies, and national and international NGOs. Few organizations did not respond but some did, the response received were recorded, transcribed, analyzed, and coded based on different key themes of this research. An analysis of the policy literature and several informal conversations help to understand the institutional response in both nations.

Disaster-Induced and Other Vulnerabilities in Indo-Nepal Tarai Region

The Indo-Nepal Tarai regions, owing to its geographical location, every year face thrilling rainfall, seismic activities, and landslides. The region, due to regular occurrence of natural disasters, bears heavy loss of lives, property, and infrastructural assets. In fact, the number and intensity of catastrophic events seem to have been on the increase because of various natural and human persuaded reasons.

The insular areas of the region are vulnerable to not only the intense cyclonic frequency but also the plate tectonic activities. The region bestrides the edge of fault line between the Indian and the Eurasian major tectonic plates. These plates push each other and relocate the crust of the earth. The strain built up by the pushing of plates along the fault line intermittently causes earthquake. The region is well known for one more natural hazard, that is the recurrent floods. Nepal has a large number of waterbodies consisting of 6000 rivers and rivulets totaling about 45,000 km in length. They are the lifeline of the region. They provide water for drinking and irrigation of vast agriculture area. Though, in monsoon seasons, because of overflowing, they become the reason for loss of life and property in Indo-Nepal Tarai region and other areas.

Other than monsoon floods, the region is also exposed to one more type of flood that is “bishyari.” It has become more frequent with climate change. “Bishyari” happens when a river is blocked by a landslide penetrated by a pool of water that forms upriver of the blockage. The “bishyari” is hard to foresee and have been a menace to assets, infrastructure, and life. On the basis of many environmental risk indices, the Indo-Nepal Tarai region is recognized as one among the environmentally most vulnerable areas in the world.

The region is facing several simultaneous challenges related to climate change such as frequent glacial lake overflow at upper region, flash floods causing damage, landslides, erratic precipitation, and variations in the pattern of temperatures, winds, fog, and hailstorms.

In the background of climate change-related environmental vulnerability, an important concern is the speedy growth of the population, which is a known factor for environmental degradation such as deforestation, soil erosion, air pollution, water pollution and accumulation of unmanageable solid waste (Vulnerability Profile of Nepal, United Nations, 2018).

The social, economic and demographic features of Indo-Nepal Tarai region traversing with geophysical and hydrometeorological processes present extreme social vulnerability of the area.

The backwardness related to these features is rooted in a historically lethargic development process. In the recent past, the focus of development work remains in capital cities and only in few urban centers of Nepal and bordering Indian states, which sideline the rural areas in the Mountain, Hill, and Tarai regions from the development. The social and economic condition become more worse due to nonexistence of infrastructure, energy, government answerability and financial resources. (UNDP 2016).

According to a study done by Aksha, S.K., Juran, L., Resler, L.M. et al. in 2018, Tarai districts comprise a significantly large number of villages and municipalities with high social vulnerability. This study highlighted that the geographic distribution of the principal component like death-related vulnerability and poor infrastructure is concerted in the Tarai region. It is seen that almost all villages and municipalities showed high vulnerability in relation to poverty and poor infrastructure. Another factor, favourable social conditions, displays higher levels of vulnerability all over the Tarai region relatively vulnerable areas for migration and gender are distributed across the entire Tarai region. The highest levels of social vulnerability for component ethnicity are in the western part of Nepal, as well as the eastern Tarai region. Another component education, reveals higher vulnerability in central and eastern Nepal – particularly the eastern Tarai region – with small areas of the western Mountain region also showing greater levels of social vulnerability (Aksha et al., 2018).

In the central and eastern Tarai regions, many villages and municipalities, which comprises inconsistent population, are kept in the High and Medium vulnerability class categories, whereas population centers in the western Tarai region are mainly kept in the category of medium or lower level of vulnerability. This categorization corresponds to the fact that the central and eastern Tarai regions drop back in education and health even though being home to a huge number of poor, Dalit, and minority groups (Sharma et al. 2014).

In this way natural hazard risk along with social vulnerabilities place this region in a high disaster risk zone.

The traditional approach to disasters management in Indo-Nepal Tarai region mostly remains the focus of post-disaster management by countering the events and rebuilding destructed assets after the disaster has happened. Generally, the main stakeholder's response remains reactive rather than proactive, and because of this approach loss of life and economic losses were found to be very high in the region.

In the last few years, the region has started efforts to institutionalize and mainstream the disaster risk reduction and management activities. Though the degree is not same, both countries in the region arrange to set up institutional structure and an ex-ante approach to lessen the impacts of hazardous incidents at the national and subnational levels.

Institutional Structure and Mechanism

In both countries the governments are working to decrease the disaster risks and their management, therefore many organizations have been set up and facilitated to work in this area.

In Nepal the policy, regulatory, and legal frameworks have facilitated to establish proper Disaster Risk Reduction and Management (DRRM) structures and mechanisms for the country and its respective government agencies.

The legal devices also provided clear directives to concern ministries and departments to establish and operationalize their corresponding DRRM institutional structures.

Nepal's contemporary landscape of disaster governance is guided by its Constitution 2015 and the Disaster Risk Reduction and Management (DRRM) Act, 2017. The DRRM Act 2015 gives various legal, institutional, and operational directives to the federal government with organizational arrangements such as the National Council, the Executive Committee and the NDRRMA, under Ministry of Home Affairs, which is directed by the Home Minister. The DRRM Act allocates full and specific mandates to the NDRRMA to lead, facilitate, and support federal, provincial and local governments on disaster risk reduction, response, and reconstruction. All federal ministries and departments have set up units and assigned officers to undertake DRRRM-related work. Federal agencies, like the Ministry of Federal Affairs and General Administration (MoFAGA) provide help to local governments by preparing and sharing model laws such as the model DRRM Act. The local leaders and experts during the interaction for this study mentioned that these supports remained helpful in strengthening the local government's DRRM governance.

The Ministry of Home Affairs' jurisdiction provides a provision for a network of emergency operation centers, which includes one National Emergency Operation Centre (NEOC) and 77 District Emergency Operation Centres (DEOC) for each district. The Prime Minister's Disaster Management Fund in Nepal is a well-established fund for bigger disaster response. There is also a Central Disaster Relief Fund. The federal government also has provision of an unfrozen (designated) fund, targeting provincial and local governments for disaster management activities. In Nepal, the Council of Ministers works at the top followed by the Ministry of Home Affairs (MoHA) in which the Disaster Management Section is situated, followed by the various Departments.

The National Disaster Management Authority (NDMA), headed by the Prime Minister is the top institute for Disaster Management in India. Setting up the NDMA and starting institutional mechanisms at the State and District levels are directed by the Disaster Management Act, 2005. NDMA is delegated to lay down the policies, plans, and guidelines for Disaster Management. India envisages the growth of an ethos of Prevention, Mitigation, Preparedness, and Response. NDMA has five major divisions, viz., Policy and Plans, Mitigation, Operations and Communications and Information and Technology, Administration and Finance.

The NDMA is responsible for laying down the plans, policies, and guidelines for disaster management and the states are preordained to formulate policies and plans in accordance with the guidelines laid down by the NDMA. At the state level, institutional arrangements are flexible. States which face frequent disaster have set up their own Disaster Management Departments whereas others have also set up smaller Disaster Management Authorities that sit within a Department of Revenue.

UN organizations and other central level government departments occupied the second tier of institutions in both the countries. In Nepal this consist the Nepal Risk Reduction Consortium (NRRC), which comprises the Government of Nepal, multi- and bilateral donors, and humanitarian and development partners working together for Disaster Risk Reduction and some protuberant national NGOs. In Nepal, the Kathmandu Valley municipalities were inserted below reflecting the power of the municipal governments in the Kathmandu Valley, which is seen to dominate the country.

A third tier included INGOs (International Non-Governmental Organizations) in Indian states and Nepal and multi- and bilateral donors and development banks, which are more active in Nepal.

The UNDP has had a long existence in Nepal and since the early 1990s supports the various organizations to contribute in disaster risk reduction. It also helped in setting up the NRRC. Designed around 50 priority areas or flagships. According to Panday, more than 60% of Nepal's development budget is contributed by bilateral and multilateral donors (40% being state generated), of which 70% goes through the Finance Ministry (i.e., to government). The rest goes through the Social Welfare Council to NGOs and civil society groups. NGOs in Nepal are predominantly important for the execution of DRR projects indicating the limited capacity of the government at the local level (Pandey, 2013).

In comparison, presently India has a robust government structure for disaster risk reduction and donors and multilateral agencies play not as much of a significant role in determining the agenda (Samantha Jones et al., 2016).

Within the broad institutional framework this study is mainly looking at the three types of selected institutions which are working in Indo -Nepal Tarai region: (1) International institutions – UNDRR, CARE International, CARE India, CARE Nepal, and SAARC, (2) National NDMA (India), NCDM (Nepal), Rapid Response (NGO), Gram Niyojan Kendra, and (3) local organizations: Dehat and Maity (Figs. 1 and 2).

International Institutions

UNDRR (United Nation Disaster Risk Reduction)

UNDRR (United Nation Disaster Risk Reduction) was established in 1999 with a vision to facilitate the implementation of the International Strategy for Disaster Risk Reduction. It was mandated by UN General Assembly. It is a leading International Agency to ensure coordination among UN systems and regional organizations on disaster risk reduction and in humanitarian activities. UN adopted an action plan to develop the UN Plan of Action on Disaster Risk Reduction for resilience on March 2013. This action plan mainly focuses on disaster risk reduction and it also seeks to integrate disaster risk reduction and coordination among countries that come under

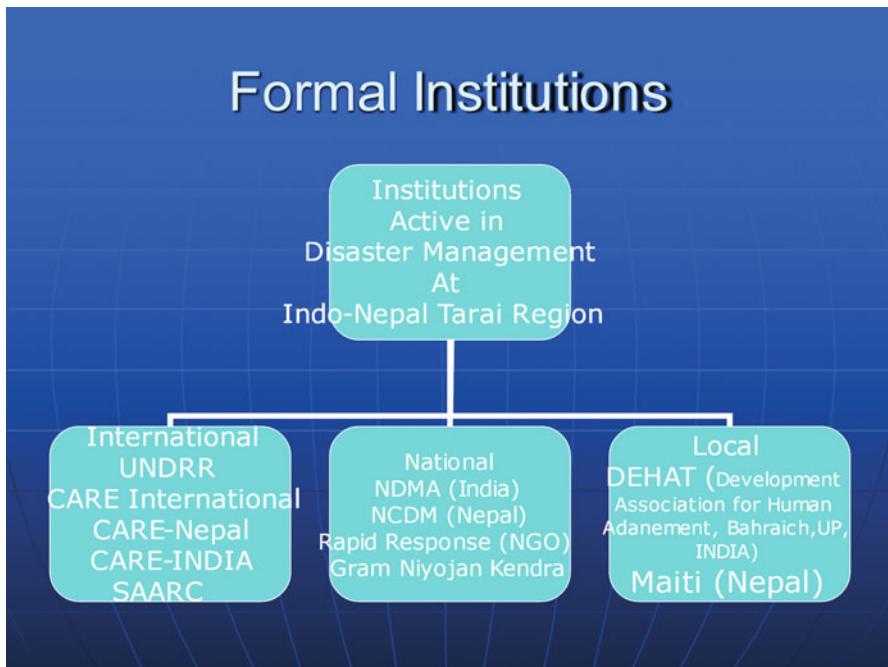

Fig. 1 Formal institutions working at Indo-Nepal Tarai region. (Source: Author)

the UN country level program and activities. According to UNDRR, disasters force approximately 26 million people into poverty every year. UNDRR publishes “The Global Assessment Report of disaster risk reduction,” biennially. UN adopted the Sendai framework for disaster risk reduction which aimed at seven goals. This framework is a first major agreement of the post-2015 development agenda. Under the UNDRR, the Global Platform for Disaster Risk Reduction is a forum for information exchange. At this forum countries share their knowledge and latest development aiming toward better communication and coordination. The core objective of this program is to enable the governments, NGOs, researchers, and UN organizations to share their experience and guide them for implementation of global disaster risk reduction agreements.

UNDRR’s regional offices work as the supporting secretariat for regional platforms. From 2005 to 2015, regional platforms for disaster risk reduction grew progressively. In the concluding years of the Hyogo Framework, participants of these platforms asked for specific acknowledgment of regional mechanisms to contrive and manage disaster risk reduction.

During the post 2015 Sendai Framework era, regional platforms endured a significant prospect to resolve transboundary issues around disaster prevention and

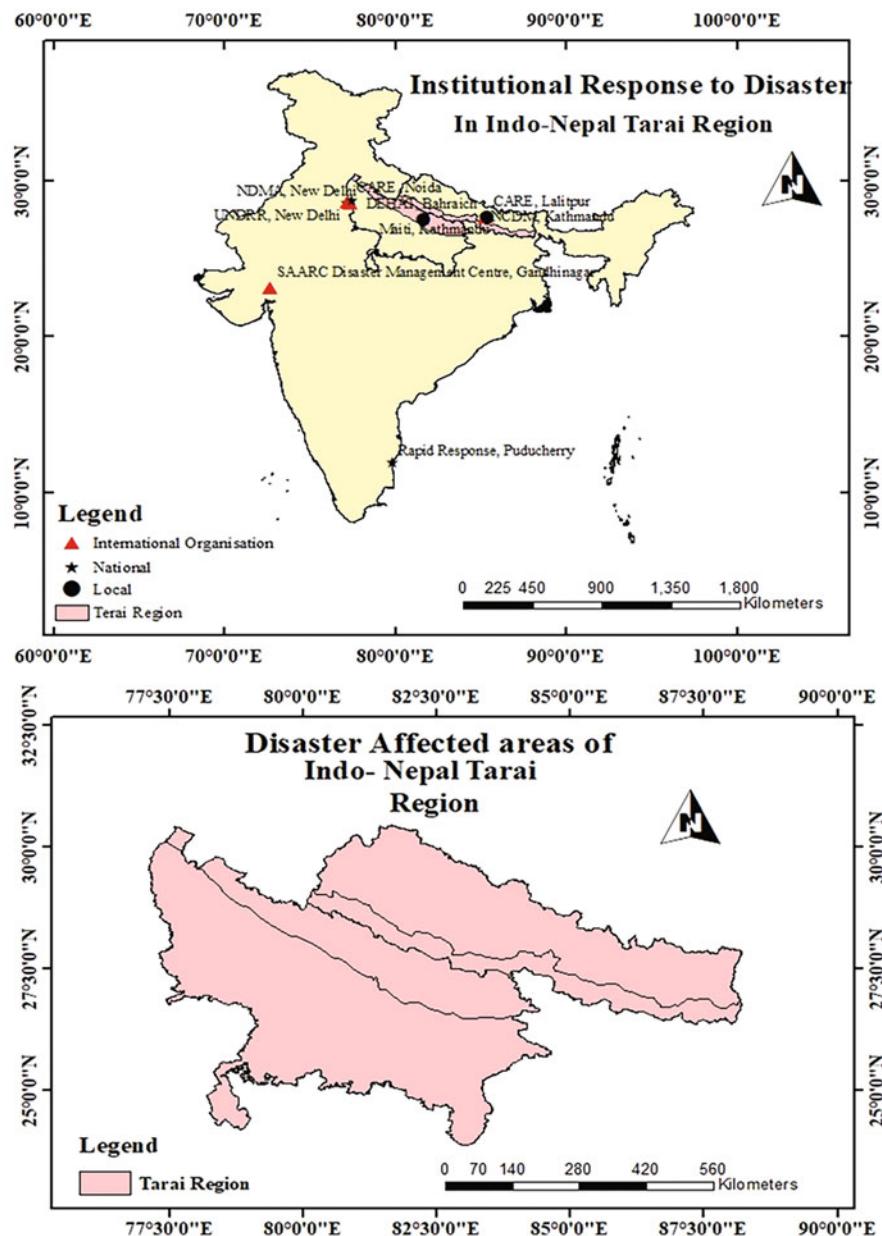

Fig. 2 Institutes working in disaster affected Indo-Nepal Tarai region. (Source: Author)

preparedness, make available leadership and direction and suggest appropriate solutions to tackle disaster risks and to construct the resilient nations and communities.

The UNDRR Regional Office for Asia and the Pacific (ROAP) do disaster risk reduction efforts across the Asia-Pacific region. ROAP works with governments, United Nations Country Teams, regional and international organizations and other stakeholder groups to safeguard people from disasters, develop resilience and promote sustainable development.

ROAP work in 39 countries and 13 territories in total. It is based in Bangkok, Thailand with a subregional office in Suva, Fiji, a liaison office in Kobe, Japan, and an office for North-East Asia in Incheon, Republic of Korea. India and Nepal both countries through their Ministry of Home Affairs work with ROAP (*Disaster Response in Asia and The Pacific: A guide to International Tools and Services, 2013*).

UNDRR also supports to build the capacity of United Nations country teams to update the incorporation of DRR into nation's analysis and programs. Apart from this UNDRR has given guiding principles to intergovernmental organizations in the Asia-Pacific region, such as ASEAN and SAARC, to enhance their cognizance of disaster risk reduction and incorporating it in their sectoral plans. Other areas in which UNDRR has worked are mainstreaming the disaster risk reduction into other sectors, integrating the DRR tools into the humanitarian action cycle and developing the resilience in micro, small, and medium enterprises. The Indian government contributed US \$ 1 million in November 2016 in the sideline of 7th Asian Ministerial Conference for Disaster Risk Reduction and signed a Statement of Cooperation to encourage regional capacity buildings for the Asia-Pacific Region in the area of Disaster Risk Reduction (DRR). However, the presence of UNDRR and ROAP does not help in bringing any cooperation between India and Nepal to tackle the disasters risks in the Indo-Nepal Tarai region.

CARE International

Another very important international organization is **CARE International**, which is very actively working in both the countries. It is an international organization seeking for hope, tolerance, and social justice and also helps people to overcome poverty and live life in dignity and security. CARE International has 14 members of global network, three candidate members and one affiliate member. It works in 97 countries to save lives and its mission is to defeat poverty and achieve the goal of social justice (2017 annual report). Care has no biased nature, it provides help regardless of any discrimination on caste, color, creed, or race. It promotes the protection of humanitarian space and works solely for vulnerable groups particularly for women and girls. It follows a set of programs in emergencies that includes rehabilitation and long development work.

CARE Nepal works in partnership with state agencies, donors, NGOs, research institutes, private actors, and native communities. It works to reduce gender-based violence, enhance women and girl child leadership and their voices, raise the awareness on sexual reproductive health, inclusive governance growth, fulfill food and nutrition security, and disaster risk reduction and climate change. In May 2015,

when Nepal was rocked by two devastating earthquakes of 7.8 and 7.3 magnitude subsequently, CARE served emergency relief with the help of partners in four of the worst affected villages. The villages are Gorkha, Sindhupalchowk, Dhading and Lamjung covering approximately 1,30,000 people including its capital, Kathmandu. After the earthquake CARE responded very quickly; under the program named Shelter, it not only rescued people but also provided shelter to families whose homes were heavily destroyed. CARE provided them shelter repair kit, which helped them to rebuild their houses stronger and sturdier than before. Care Nepal steadily donated at the time of disaster and also appealed before the world community for donation during flood, earthquake, and landslide emergencies in Nepal. These appeals attracted millions of dollars in disaster aid, which meant that they were working on ground zero in Nepal including Indo-Nepal Tarai region and had better sense of coordinating relief efforts.

CARE in India is working over the 68 years, and in all these years it has made a considerable shift by providing direct service to the poor and vulnerable groups. CARE India focuses on planning and comprehensive projects in health, education, livelihood, disaster preparedness, and response. CARE India has a “Disaster Preparedness and Response Strategy,” which maintains the Emergency Response Teams at National and State level in the country. This emergency team is specially trained and prepared to provide relief and rescue program. CARE India also partnered with various states like UP, Bihar, Tamil Nadu, West Bengal, etc. to build their capacities on disaster preparedness and response and also remains active in Indo-Nepal Tarai area, fall in the boundaries of UP and Bihar. In 2007, during the flood, CARE rescued peoples from Uttar Pradesh and Bihar. But CARE NEPAL and CARE INDIA never partnered for disaster management while working in the Indo-Nepal Tarai region.

SAARC (South Asian Association Regional Cooperation)

The South Asian Association Regional Cooperation (SAARC) was established on 8th December 1985. India and Nepal are members of the SAARC association. The SAARC secretariat was established in Kathmandu in 1987. The objectives of the SAARC association are to accelerate economic growth, social progress, and cultural development in the region and to promote the mutual trust between SAARC nation by enhancing the understanding among them and strengthen their relationship so that they can make a common interests and fight against the climate change with one accord. SAARC being a regional cooperation is highly concerned with preservation of environment and disaster risk preparedness and response.

In view of the regional dimensions of natural disasters, the third SAARC Summit had specially made an inclusive regional study on the causes and consequences of natural disasters. A SAARC Meteorological Research Centre was set up in Dhaka in 1995 and a SAARC Coastal Zone Management Centre was established at Male in 2004.

A Special Session of the SAARC Environment Ministers in June 2005 espoused the Male Declaration, which insists on formulation of a Comprehensive Framework of Disaster Management in South Asia. The 13th SAARC Summit at Dhaka in

November 2005 accepted the proposal of regional cooperation for preparedness and mitigation of national disasters and approved the offer of India to set up a SAARC Disaster Management Centre (SDMC) in New Delhi. The center was inaugurated on 10th October 2006. Later, in November 2016, the Interim unit of SDMC was shifted to Gujarat Institute of Disaster Management Campus. The scope of the center was expanded by merging the other regional erstwhile centers such as SAARC Meteorological Centre (SMRC Dhaka, Bangladesh); SAARC Forestry Centre (SFC Thimphu, Bhutan); and SAARC Coastal Zone Management Centre (SCZMC Male, Maldives) with SDMC. The center is steadfast to work according to the approved blue print of SDMC-IU. The center is entrusted with the responsibility to support Member States in their DRR initiatives through application of Science and Technology, knowledge from multiple disciplines, exchange of good practices, capacity development, collaborative research and networking in line with the global priorities and goals and other relevant frameworks adopted by Member States.

In 2011, the SDMC developed and approved the SAARC Agreement on Rapid Response to Natural Disasters (SARRND) to provide more coordinated, cooperative and planned efforts to reduce disasters risks in the region (Cook and Chen, 2020). The agreement consists of protocols for disaster relief and emergency response, use and mobilization of resources as well as coordination of response operations. It calls on countries to “earmark assets and capacities for regional standby arrangements on a voluntary basis.” The provisions also include the setting up of a dedicated rapid action force for disaster management. However, SAARC leaders have thus far “failed to gather consensus on the issue, and this remains a point of contention.”

In the last few years SAARC has been trying to develop comprehensive strategies for enhancing preparedness for extreme weather events, pandemic and geological disasters like earthquake through organizing seminars, webinars and meetings. In these events experts from both India and Nepal participated and shared their understanding along with experts from other member states. India and Nepal actively participate in the SAARC STORM (Severe Thunderstorms: Observation and Regional Modelling) program taken up by SAARC Meteorological Centre (SMRC), Dhaka in association with Bangladesh Meteorological Department (BMD), Dhaka, Bangladesh; Department of Hydrology and Met Services (DHMS), Thimphu, Bhutan; and Department of Hydrology and Meteorology (DHM), Kathmandu, Nepal; and India Meteorology Department (IMD), India.

STORM Program was comprehended as a cooperative scientific endeavor between SAARC countries for improving prediction of severe storms frequenting India, Nepal, Bhutan, and Bangladesh. ISRO’s commitment toward the project includes supply and installation of meteorological equipment’s including 50 numbers of Automatic Weather Stations (AWS), 4 numbers of GPS Sonde Stations with associated consumables and a Doppler Weather Radar (DWR) in Bangladesh, Bhutan and Nepal (<http://saarc-sdmc.org/implementation-saarc-storm-project>).

Experts from India and Nepal along with experts from other member countries also participated in South Asian Disaster Management Exercise (SAADMEx) in November 2015. They undertook a massive simulation and field training exercise known as the South Asian Disaster Management Exercise (SAADMEX) organized by India, it sought to “test intergovernmental coordination efforts, create synergy and

synchronise efforts to institutionalise regional cooperation on disaster response among the member countries.” One of the joint field exercises include an earthquake scenario. This allowed participating teams to observe their own abilities in disaster response, while also enhancing coordination efforts with other stakeholders.

India and Nepal have been provided relief and food security during the period of floods, earthquake and in other disasters in the Indo-Nepal Tarai region from SAARC food bank; under the SAARC Food Bank Agreement 2007, there is a provision for stocking wheat and rice in member countries. In times of disaster a member country can request for these food grains.

Various policy mechanisms at the regional level are codified the disaster mechanism hitherto execution of mechanism so far not remain successful. South Asia still does not have a functional and effective regional HADR (high availability disaster recovery) mechanism and efforts to improve coordination and integration remain a sluggish and irregular process. This is clear from the fact that there has been no joint arrangement of any SAARC level contingent at the time of regional emergencies in the past few years. For example, in an aftershock of the 2015 Nepal earthquake, assistance from six South Asian countries were given bilaterally with very less coordination at the regional level.

While the SDMC has attempted to produce guidelines and conducted technical disaster response training for SAARC member states, scholars point toward the lack of political support from its members as one of the factors preventing it from fulfilling its mandate effectively.

One of the respondents gave an opinion that the absence of multistakeholder approach, highly bureaucratic functioning, low priority given to capacity building for Disaster Management compared to traditional governance concerns such as national security and the need for economic development make SAARC almost ineffective in the Disaster Management specially in the transborder areas like Indo-Nepal Tarai region.

Though individual countries in South Asia have started their own national disaster management frameworks and structures, this has not yet decoded to tangible cooperation at the regional level. In reality, quite a few respondents indicated that South Asian states preferred ad hoc bilateral engagements during the disasters rather than following a coordinated comprehensive approach.

National Institutions

National Disaster Management Authority, India was established through the Disaster Management Act in December 2005. It is headed by the Prime Minister of India. NDMA is responsible for framing policies, plans, and guidelines. Its sole purpose is to coordinate response to natural disasters or human-induced disasters and enhance the disaster resiliency and improve capacity building. NDMA coordinates with State Disaster Management authority (SDMA), other government agencies and nongovernmental organizations to ensure a holistic, proactive and distributed approach. The Disaster Management Act of India focuses on prevention, mitigation, disaster preparedness and relief. The agency promotes people’s participation in order

to mitigate and prevent disaster, which generates a prompt and efficient response during disasters.

In 2016, NDMA adopted a new Disaster Management plan; the basic function of this is to give direction to all phases of disaster management cycle. The NDMP is consistent with UN Sendai framework for disaster risk reduction 2015–2030. India is following the recommendations of Sendai Framework to reach the global targets set up by United Nations. NDMA has developed a GIS system India Disaster Resource Network (IDRN), which collects data from the states based on which a decision support system is being developed. IDRН, which is initiated by MHA in collaboration with UNDP; BHUVAN, which is the single largest web GIS portal for free data and services over India; multilayered GIS platform by NDMA & NIC; web-based composite risk atlas (WEBCRA); geo-enabled messaging platform; and National Database for Emergency Management (NDEM). It was used in Uttarakhand floods very effectively. Neighboring states like Nepal can also use this database for disaster management. NDMA through MHA is actively coordinating with National Disaster Risk Reduction and Management Authority (NDRRMA), Nepal for disaster risk reduction. **The National Disaster Response Force (NDRF)** is a specialized force to serve in the special situations like disaster. NDRF team was deployed in Nepal to provide relief and aid equipment after the 7.8 magnitude earthquake in April 2015. NDRF did commendable work in Indo-Nepal Tarai region too.

The NDRF team in Nepal rescued 11 injured people and repossessed 133 dead bodies from the debris. The team members also set up 06 medical camps and looked after 1219 people. NDRF assisted the MHA and NDMA to deliver 1176.571 tonnes of relief materials as donation arranged by various agencies to quake affected people of Nepal via various routes. The different teams spread out to different areas in the Kathmandu district and commenced USAR operations at once at Balkhu, Kopan, Gongabu, Tanhu Hospital, Balaju, Basundra, Maharajganj, Brijeshwari, Shobha Bhagawati Bridge, KV Army area, Tilganga, Sondara, White Gumba, Shankhu, PM residence area, Balaju bypass and Kathmandu to assist the Nepalese Authority in “Humanitarian Assistance and Disaster Relief” (HADR) work.

On the basis of MHA directions, NDRF sent its 04 teams on 25th April 2015 to Supaul, Motihari, Darbhanga, and Gopalganj in Bihar and 01 team to Gorakhpur in UP. Next day on 26th April 2015 a team deployed at Motihari further diverted to Raxaul (Bihar). Teams positioned in Bihar did rescue operation and shifted 180 patients from destructed buildings to safe places in Darbhanga Medical College and Hospitals. Another team, which was working at Raxual, East Champaran helped State Government in shifting of 409 persons coming from Nepal to Relief Centre at Hajarimal High School, Raxual.

The work of NDRF in Nepal was praised in media and social media all over the world but China and Pakistan, it is believed, have criticized and communicated to the Nepalese government that the Indian Government was more interested in self-promotion than in sincerely extending help. Reporters accompanying Indian relief helicopter missions were cited as an example of Indian aggrandizement (Rahul Kanwal, 2015). However, the Indian government denied this and NDRF continued its work.

The National Disaster Risk Reduction and Management Authority (NDRRMA), Nepal is relatively a new agency mapped within the Ministry of Home Affairs. It is currently working on the five priorities; first one being risk assessment and setting up of a national disaster risk assessment portal. The agency is also working on hazard assessment with other departments that can convert the assessments into risk information that's accessible down to the municipal level. The risk information helps build capacity of the local government and make informed decisions. During the pandemic, the NDRRMA developed COVID portal wherein near real-time data is reported. The second priority is on early warning system – impact-based early warning system that includes not only communication but also capacity building specially landslide EWS. The third area is reconstruction and the recovery works. Fourth area is effectiveness in the response system; support has been received by UNSPIDER in terms of training users on using satellite-based system. The last area is disaster risk financing. It highlighted the need for similar capacity building programs and exchange of knowledge within the region. The organization has given special focus to Nepal Tarai region while developing these programs.

National Centre for Disaster Management (NCDM) Nepal NCDM was established by the Nepal government in February 2002 with an aim to effectively mitigate the impact of disasters in the country. NCDM is committed to enhance the capacity of the local communities in disaster preparedness by the way of training and awareness. The agency firmly believed that people's participation to mitigate the effects of disaster is an effective mean. The vision of NCDM is to adopt a pragmatic approach to work in the disaster preparedness so that Nepal can become a safer country from disasters. To reach out the goal, the center is always looking forward to establish an environment of trust, friendship, and cooperation among the national (governmental and nongovernmental) organizations as well as international organizations. Because of its geographical position, Nepal is highly prone to disasters, keeping that in mind the disaster statistics of Nepal always supports an urgent need for disaster risk reduction program. Therefore, Nepal has also adopted the Hyogo Framework Action (HFA) to assign a national mandate toward DRR through various programs.

The respondent from NDMA and NDRRMA denied any direct coordination between National Disaster Management Authority, India and The National Disaster Risk Reduction and Management Authority (NDRRMA), Nepal in Indo-Nepal Tarai region.

GNK (Gram Niyojan Kendra) India

Gram Niyojan kendra is a national-level organization, which is working in rural India to bring social equality, justice, and development since 1977. Its main office is located at Adhyatmiknagar, Dasna, Ghaziabad and the project offices are located Nautanwa, Mahrajganj (Uttar Pradesh), and Roopwas, Bharatpur, Rajasthan. This institution has strong belief in Gandhian philosophy and its focused area of work is

the marginalized community. The objectives of the institutions are to provide several facilities to strengthen the women, children, and other disabled and marginalized people, to bring rural community closer with the state and regional organizations and assist them, to conduct research and organize seminars and conferences on social and development issues at various levels. Currently, it is working in seven states of India. In Maharajganj, GNK is actively involved in disaster risk management, especially livelihood generation for women and other vulnerable groups of people, education, training of health attendants, and control/prevent involvement of children in smuggling/prostitution and trafficking. One of the representatives from the organization stated that with CSR partnership and government help GNK organized and conducted various activities to reduce the disaster risk by empowering the vulnerable groups but at the border areas of two countries and in those cases where trafficking takes place and traffickers belong, the situation becomes very difficult to handle. Even running a simple development program in border areas becomes a challenging task (<http://gramniyojan.org/about-us/objectives-of-the-kendra>).

Rapid Response NGO (India)

Rapid Response is a nonprofit organization, which is committed to provide disaster response and relief to vulnerable communities in almost every state in India. It is also active in Bihar and Uttarakhand. This NGO also provides help to marginal communities in non crises situation aiming to make a better, safer, and resilient India. Rapid Response contains three programs, which are rescue and medical assistance, relief, and rehabilitation. They provide relief kit, medical kit, hygiene kit, educational kits, and other essential items to families affected by natural disasters. The Seed Ball is a special project of this organization, which focuses on increasing green cover across India, especially in cyclone or drought affected areas. The process involves making golf ball-sized mixture of soil, seeds, and compost and scattering it in suitable places for trees to grow. Rapid response team helped thousands of people of Bihar in 2016 floods and recent floods in Patna, which is caused by high intensity monsoonal rain. It is actively working in many districts of Bihar and Uttarakhand, which are also the part of Indo-Nepal Tarai region. One of the respondents informed that the organization's main challenge in the bordering areas is in gaining the trust of the people and the administration.

Manav Seva Sansthan “SEVA”

Manav Seva Sansthan “SEVA” is a nonprofit organization which is currently working in several districts of Uttarakhand, Uttar Pradesh, Bihar and West Bengal. It was established in 1988 with a mission to ensure socioeconomic development of the poor people, women in vulnerable situation and children deprived of basic rights through community-based area development approach. The major focus of MSS is protection of women and children. Current portfolios of MSS are working on cross-border child right, child protection and anti-human trafficking campaign along with

gender rights and women empowerment, health and HIV. It is also focusing on inclusive growth of schedule cast/schedule tribe community. The organization also expands its focus on sustainable agriculture, sustainable livelihood, and migrant rights. The prime focus of MSS is disaster risk reduction, relief and response and climate change. It provides help related to livelihood, rehabilitation, food, and safety to people returning to normal life after disasters like flood, earthquake and other types of disasters. MSS has vast experience of addressing problems related to disaster through various approaches of supply of essentials, medications and counseling. In 2015, during the Nepal earthquake, it provided non-food things to victims (<http://www.manavsevaindia.org/disaster-management.aspx>). MSS has a strong General Body, which has members from all walks of life including those from client communities.

The Governing Body of 11 members are elected by the General Body. The Governing Body has a 5-year term. The Governing board members comprise eminent personalities from diversified fields. The MSS management comprises the Executive Director, Director and manager/officers handling programs, human resource, finance, and administration. There is a Core Committee with representatives from the Governing Body, executives, and staffs. This committee meets quarterly to reviews program, monitors budget, and decides on new programs.

The organization follows consultative decision-making processes. This institute is more active in Gorakhpur, Kushinagar, Maharganj, Balrampur, Bahraich, Basti, Siddartha Nagar, Santkabir Nagar, Deoria, and Ballia districts of Uttar Pradesh. This area has peculiar physical or social characteristics. Some districts are very close to Indo-Nepal border and the area is surrounded by major rivers like Gandak, Narayani, Rohin, Rapti, etc., which cause floods almost every year and the demographics of the area are among mostly backward districts of the country.

Mr. Rohan Sen, Program Manager mentions that this institute and its staff face various challenges during the work; these are mostly economic, physical, and phycological. He said, socially they did not face any problems. He said the most important challenge includes constraints in fulfilling all the needs of the target group because of the large population and less resources and funds. He said the other challenges in these areas are poor road connectivity along with water loggings and forest areas that create physical hurdle to reach on time to help the affected people.

The other problem is psychological as the expectation of communities are high; so in times of crisis, fulfilling all the expectation becomes challenging and invites criticism.

Local NGOs

DEHAT (Developmental Association for Human Advancement) India

DEHAT was founded in year of 1989 in Bahraich in Uttar Pradesh. In initial 10 years DEHAT served as a school for "Tharu" tribal villagers and forest children until being registered under the Society Registration Act 1860 on the 21 August 2000. This NGO started with the belief that without securing the development of children no

society can achieve sustainable development. This organization firmly assured the children survival, protection and participation with the aim to educate, enable, and empower the underprivileged. Therefore, the core work area of this institute is to assure the safety of children and it delivers service in the most backward rural region in India. The main objective of this organization to rescue children from being vulnerable. DEHAT is working with worldwide partner to empower and advocate for the most vulnerable community. DEHAT is inspired by the United Nations Convention on the Rights of Child (UNCRC) and is committed to shape a child's life safely by bringing together education along with women literacy and empowerment, human trafficking protection, sustainable livelihood option and maternal and child health (<https://dehatindia.org/our-story/about-us>). Though the organization is not directly related to disaster management, it actively provides support to the vulnerable population affected by various forms of disasters. A worker from DEHAT informed that acute poverty is the main challenge in this region, which places constraint on any innovative development program.

Maiti Nepal

Geographical, economic, and social landscape of Indo-Nepal Tarai region provide all suitable conditions for most heinous crime of today, that is human trafficking. The region is economically poor, socially backward, geographically fragile and being a transit zone is identified as a prominent point of trafficking.

Maiti is an organization that works to protect girls and women from various types of abuse like child and sex trafficking, domestic violence specially during a disaster and in the post disaster phase. In Nepali "Maiti" means the home of a girl's biological parents. This institute was established in 1993 with the aim to make Nepal free from sexual exploitation against child and women. It is also actively working in the legal sector to provide justice for the victimized girls and women. Its main focus is to prevent human trafficking for the various types of illegal activities by means of raising awareness level of community and empowering women. The objective of the organization is to rescue the victim of human trafficking and rehabilitate them by providing education and necessary counseling. Currently it is operating a rehabilitation center in Kathmandu, as well as at the transit zone of Indo-Nepal border. This NGO organizes prevention programs by giving information about human trafficking to vulnerable girls and it also provides temporary shelter houses for the victims (<https://maitinepal.org/about-us/introduction/>).

Maiti Nepal is quite successfully rescuing thousands of girls and women from trafficking but it faces some criticism; it has been found that Maiti does not always respect the will of the victims and is also criticized for not providing proper rehabilitation to former prostitutes. But one of the respondents informs about the various challenges faced by the organization, most importantly the social stigma attached to the trafficked person, which sometimes do not allow the organization to work according to the wish of the rescued person.

Conclusion

This analysis shows that disaster management in Indo- Nepal Tarai region still has a piecemeal and an ad hoc approach. The South Asian Association for Regional Cooperation (SAARC) has identified the need to associate efforts with its active role to reduce the effects of disasters through awareness and preparedness for rescue and relief. To this end, SAARC has set up a SAARC Disaster Management Centre (SDMC) in 2006 and many warning centers. But when in 2015 devastating earthquakes ravaged Nepal, it showed the actual limits to a regional disaster management and response. Around 4175 troops from 18 countries were positioned for rescue and relief operations. India was the first neighbor to join the Nepalese disaster response. Except Afghanistan and Maldives, all SAARC member states tried to help in the Nepalese disaster. The United States, United Kingdom, China, Japan, Germany, and South Korea were among the other countries providing help in rescue, relief, and rehabilitation of victims. But SAARC was not prepared for the right response once the support reached Kathmandu. Its institutional presence in rescue and relief operation in Nepal was missing. The absence of a pre-coordinated plan or resource management formed strains even in the capital. The condition in the inaccessible areas was even bad, where the road networks were destroyed and helicopters were the only mode of carrying relief materials.

SAARC has problem of indecision and implementation of programs, including disaster management measures. Though, the better hope for the regional approach to disaster management in SAARC is the commitment from all the member states on regional effort to reduce the loss and relieve the victims as early as possible. However, the implementation is slow in South Asia, members are still very optimistic to address issues like poverty alleviation, food security or disaster management and have not refused to take coordinated actions in these directions.

While in Nepal inadequate intergovernmental synchronization with provincial and local government is partially due to a paucity of human resources, the problem at federal level has more to do with bureaucratic siloes. Therefore, the formation of DRRM institutional and legal structures, and the modest fulfillment of staffing requirements may be inadequate to address intergovernmental coordination gaps. In India too Tarai districts fall within the political boundaries of different states, which have different disaster response mechanism. Even the Central Government is not looking at the need to develop a comprehensive disaster management plan for this region. Categorization of disaster is also different in both countries, which create a major hurdle in coordinated response during the emergencies.

India and Nepal both are mainly following top-down approach in disaster governance. The challenges of coordination and communication during crisis have more severe and obvious consequences. It has seen that several times in this region lives are lost and recovery retarded as responders and decision makers are unsuccessful in moving resources, personnel and aid in time to disaster-struck communities. Nations have moved to create frameworks intended to better handle catastrophe coordination for which turning policies into practices requires finding the appropriate balance between top-down and bottom-up engagement.

It has been stated during the online interaction by various respondents that the government and nongovernmental institutions are working without any coordination especially in this region, sometimes they are not aware about the work done or that can be done by other organizations. Therefore, NGOs fail to receive administrative support while government fails to take advantage of NGOs in disaster risk reduction program in Indo Nepal Tarai region.

It has been seen that generally at the time of disaster, institutions concentrated their activities and remain more active at the epicenter of affected areas and forgotten peripheral areas impacted by disasters, which increases the suffering of the people living in those areas. It is necessary to acknowledge them while formulating intervention strategies.

In spite of the unrelenting urgency of disaster response, the situations under which local, regional, and national authorities and residents synchronize well during disaster remain vague. International organizations despite their best efforts remain mostly unable to deliver the coordinated disaster risk reduction in the region.

Coordination at the transboundary level is very challenging. There is a lack of institutional structure, inadequate staffing, and poor functional ability to undertake designated responsibilities in these areas. However, both governments coordinated during the disasters in the past but current efforts are insufficient. This gap in intergovernmental collaboration and coordination may be determined with adequate DRRM institutional structures in place, improved staffing, and greater resource mobilization with strong political and civilian will.

Abstract

This chapter deals with the history and present activities of the state of Oregon, located in the Western United States, with respect to natural hazards and disasters under a 50-year-old planning program. The chapter deals only peripherally with the activities of the federal government and is focused upon land use planning activities in that state.

Oregon has had a statewide planning system since 1973. See Oregon Revised Statutes, Chap. 197. County and city governments must have a “comprehensive

This chapter is based on an article, *Pay Me Now or Pay Me (Much More) Later: The Practice Of Avoidance In Planning For Catastrophic Events* found at 43 *Zoning and Planning Law Report* No.2 (2020), with the permission of Thomson Reuters. Copyright © 2020.

Urban Studies and Planning, Portland State University, Portland, OR, USA

plan” to which their land use regulations and actions must conform. In turn, those plans must conform the applicable statewide planning “goals” that deal with various subject areas, including Goal 7, Natural Hazards and Disasters. Goal 7 directs these governments to inventory likely hazards and disasters (including riverine and coastal flooding, earthquakes and tsunamis, landslides and coastal erosion, and wildfires) and take steps to mitigate or avoid them. Local plans must be “acknowledged” or certified by a state agency to conform to the goals.

All local plans have been “acknowledged”; however, problems remain. Local governments sometimes avoid raising issues that may raise landowner concerns over limitations on property use and subsequent litigation. Further, local governments are underfunded to undertake further studies on potential or less understood hazards and disasters and the regulatory steps to mitigate or avoid them. The present accommodation is that no new obligation to mitigate or avoid disasters will occur unless the state agency so determines. While the state’s land use program does more in this area than other states, it could do a much better job.

Keywords

Planning · Land use regulation · Natural hazards and disasters · Flooding and coastal erosion · Earthquakes and tsunamis · Wildfires · Landslides

The news cycle brings an unremitting catalog of national and international natural disasters to the public consciousness. Hurricanes, wildfires, earthquakes, and tsunamis fascinate for a while and then fade away. For a time, disaster recovery may occupy public attention, but it is less riveting than political and social events – or the next disaster – and these items inevitably come to occupy reader or viewer interest. As such, planning to mitigate or reduce damage from these natural disasters is rarely given priority, as it is seen as too inconvenient or politically impractical to bring to reality or, in some cases, is considered a scandalous example of government overreach.

This chapter discusses the role of comprehensive planning and land use regulation in planning for, adapting to, and mitigating the social, economic, and environmental impacts of natural hazards and disasters – phenomena that are and will continue to be greatly exacerbated by climate change. (See Coastal Flooding, SCIENCECIRECT, <https://www.sciencedirect.com/topics/earth-and-planetary-sciences/coastal-flooding> (last visited Oct. 12, 2019).) We advocate ditching the default response of providing for relief and reconstruction following natural disasters in favor of the more difficult business of inventorying, analyzing, and studying significant anticipated hazards, devising optimal strategies to mitigate or avoid them, and crafting policies and regulations to prevent or reduce the damage they cause. This approach requires an adequate factual base, conscious policy choices that may prohibit development in risky areas, and adherence to regulations that carry out those policy choices. While this regime is logical, there are short-term economic and

political obstacles to its attainment. From a national perspective, this article asks whether prudent states should continue to subsidize incautious local jurisdictions that continue to permit development in areas vulnerable to natural disasters.

Let us be clear: natural hazards are always with us. (The author is indebted to Ted Lorensen, a retired assistant state forester for Oregon, who believes most “hazards” (such as flooding, landslides, and wildfires) are natural ecosystem processes and that humans “modify” at own their peril, often to the detriment of the ecosystems themselves, as well as life and property. Modifying the effects of wildfires simply through fire suppression has resulted in fuel loads increasing. Similarly, “protecting” coastal dwellings with riprap and filling in wetlands too often end poorly, as nature overcomes mankind. To build in a margin of safety, Lorensen suggests that it would be better to accommodate and mimic ecosystem processes. The Institute for Natural Resources maintains a similar view. See Inst. for Nat. Res., Managing Dynamic Forest Ecosystems (2009), <http://library.state.or.us/repository/2010/2010040114-25514/index.pdf>. While the author agrees with this approach, the accepted nomenclature of “hazards” and “disasters” is used in this chapter.) They only become tragic disasters when they inflict personal injury or property damage that could have been avoided. The subject of this chapter is the role of land use planning and regulation in preventing natural hazards from becoming disasters. With some exceptions, (Riverine flood control was a logical starting point for federal involvement, as rivers cross state lines and the Commerce Clause of the US Constitution gives Congress authority to intervene. See U.S. Const. art. I, § 8, cl. 3. While federal involvement in flooding and flood relief was occasional before that date, justified on a navigational basis, the 1936 Flood Control Act declared that flood control was an appropriate area for federal regulation and became the beginning of various flood control projects managed by the United States Army Corps of Engineers. See Flood Control Act of 1936, Pub. L. No. 74-738, 49 Stat. 1570; Joseph L. Arnold, The Evolution of the 1936 Flood Control Act (1988), https://www.publications.usace.army.mil/Portals/76/Publications/EngineerPamphlets/EP_870-1-29.pdf (noting that, in Gibbons v. Ogden, 22 U.S. 1 (1824), the Supreme Court interpreted the Commerce Clause as allowing federal involvement in public projects on rivers in the United States.) this approach is generally not available or used at a national level in the United States, since planning is more often viewed as a function of state and local government (See Organisation for Econ. Co-operation & Dev., The Governance of Land Use in OECD Countries: Policy Analysis and Recommendations: Country Fact Sheet United States (2017), <https://www.oecd.org/regional/regional-policy/land-use-United-States.pdf>.) with some amount of federally mandated planning and financial contribution, usually through grants. (See Adam B. Smith, 2018’s Billion Dollar Disasters in Context, Climate.gov (Feb. 7, 2019), <https://www.climate.gov/news-features/blogs/beyond-data/2018s-billion-dollar-disasters-context>. The Federal Disaster Mitigation Act of 2000 requires, as a condition of most federal assistance, that state, local, and tribal governments undertake coordinated disaster planning and mitigation efforts and provides some federal funds to that end. See 42 U.S.C. §§ 5121–5207. Such grants have funded the University of Oregon’s Oregon Partnership for Disaster Resilience and the Oregon Department of Land

Conservation and Development's natural hazard mitigation planning program. See personal communication from Michael Rupp to author (Oct. 17, 2019) (on file with author). Thus, for the most part, the established paradigm is that state and local governments bear the brunt of planning for natural hazards. This chapter assumes that that is the most frequent template on this subject and focuses on how natural hazard planning and regulatory implementation can be more useful tools for state and local governments in preventing natural hazards from becoming disasters.

Introduction: Natural Hazards and Disasters in the United States

The geographic diversity of the United States gives rise to many occasions for natural hazards and disasters. This chapter highlights several of the most common hazards as primary examples. We acknowledge that many other hazards exist – including tornadoes, hurricanes, volcanoes, and droughts – however, we have elected to omit them here in the interest of brevity and readability. The following catalog sets out several of the most prevalent examples and discusses the availability of data which, when properly used, enable us to evaluate the probabilities of their occurrence and avoid or mitigate their impacts.

Riverine and Coastal Flooding

Flooding is best understood by breaking the phenomenon into two categories. Riverine flooding refers to the inundation of rivers and lakes by runoff from surrounding surfaces, The United States Geological Survey identifies two types of riverine flooding:

A flash flood occurs when runoff from excessive rainfall causes a rapid rise in the water height (stage) of a stream or normally-dry channel. Flash floods are more common in areas with a dry climate and rocky terrain because lack of soil or vegetation allows torrential rains to flow overland rather than infiltrate into the ground.

River flooding is generally more common for larger rivers in areas with a wetter climate, when excessive runoff from longer-lasting rainstorms and sometimes from melting snow causes a slower water-level rise over a larger area. Floods also can be caused by ice jams on a river or high tides, but most floods can be linked to a storm of some kind.

What Are The Two Types of Floods?, U.S. Geological Surv., https://www.usgs.gov/faqs/what-are-two-types-floods?qt-news_science_products=0#qt-news_science_products (last visited Oct 12, 2019). This chapter also considers flash floods as a component of riverine flooding.) while coastal flooding is inundation of oceans beyond astronomical tide levels, usually by storm surges or a combination of storms and astronomical tides. (See Nat'l Oceanic & Atmospheric Admin., U.S. Dep't of Commerce, Understanding Coastal Flooding Terminology, <https://www.weather.gov/media/okx/coastalflood/Understanding%20Coastal%20Flooding%20Terminology.pdf> (last visited Oct. 12, 2019).) The United States Geological Survey (USGS), in

conjunction with other state and federal agencies, collects and publishes data on past floods and the likelihood of future flooding. (See USGS Flood Information, U.S. Geological Surv., https://www.usgs.gov/mission-areas/water-resources/science/usgs-flood-information?qt-science_center_objects=0#qt-science_center_objects (last visited Oct. 12, 2019).) The predictive element of these efforts is found in the USGS's Flood Inundation Mapping (FIM) program, in which significant flood risks are mapped for state and local government use. (See Flood Inundation Mapping (FIM) Program, U.S. Geological Surv., https://www.usgs.gov/mission-areas/water-resources/science/flood-inundation-mapping-fim-program?qt-science_center_objects=0#qt-science_center_objects (last visited Oct. 12, 2019); see also FEMA Flood Map Service Center: Welcome! Fed. Emergency Mgmt. Admin., <https://msc.fema.gov/portal/home> (last visited Oct. 12, 2019) (providing access to flood maps).) The Federal Emergency Management Agency (FEMA) also provides flood risk information in the form of Flood Insurance Rate Maps (FIRM), usually in terms of 100- and 500-year floodplains indicating where there is a 1% or a 0.2% chance of flooding in a given year. (See Fed. Emergency Mgmt. Admin., U.S. Dep't of Homeland Security, Definitions of FEMA Flood Zone Designations, https://efotg.sc.egov.usda.gov/references/public/NM/FEMA_FLD_HAZ_guide.pdf (last visited Oct. 12, 2019).) FEMA offers flood insurance for landowners in jurisdictions that belong to the National Flood Insurance Program (NFIP) and that use its maps to regulate structures in the floodplain. (According to the National Association of Insurance Commissioners Center for Insurance Policy and Research (CIPR), there is a need to provide for flood insurance:

Floods are the most common and most destructive natural disaster in the United States. Ninety percent of all natural disasters involve flooding, and all 50 states have experienced floods or flash floods in the past five years, according to [Floodsmart.gov](https://www.floodsmart.gov). The damage from a flood is not covered under a standard homeowner's policy. Flood insurance is a special policy that is federally backed by the National Flood Insurance Program (NFIP) and available for homeowners, renters and businesses.

Flood Insurance, Nat'l Ass'n Ins. Commissioners, https://www.naic.org/cipr_topics/topic_nfip.htm (last updated Apr. 22, 2019). The CIPR goes on to describe the NFIP, created under the National Flood Insurance Act of 1968 in response to the lack of available private insurance and the continued increase in federal disaster assistance due to floods. The NFIP is a federal program, managed by FEMA, with three objectives: to provide flood insurance, to improve floodplain management, and to develop maps of flood hazard zones. The program allows landowners in participating communities to buy insurance protecting against flood loss. Participating communities must establish management regulations in order to reduce future flood damages. This program is intended to furnish an insurance alternative to disaster assistance and is an attempt to reduce the rising costs of repairing flood damage to structures and their contents. See *id.*; see also Nat'l Ass'n of Ins. Comm'r's & Ctr. For Ins. Policy & Research, Flood Risk and Insurance (2017), https://www.naic.org/documents/cipr_study_1704_flood_risk.pdf.) While there is a degree of confidence in the accuracy of floodplain data (as periodically revised), (See Flood Map Accuracy: Hearing Before the Ad Hoc Subcomm. on Disaster Recovery & Ad Hoc

Subcomm. on State, Local, & Private Sector Preparedness & Integration, S. Comm. on Homeland Security & Governmental Affairs, 111th Cong. (2010) (statement of David R. Maidment, Director, Center for Research in Water Resources, University of Texas at Austin), <http://www.ce.utexas.edu/prof/maidment/giswr2011/docs/FloodplainMappingSenate.pdf> (expressing optimism that the new FEMA mapping program will be more accurate than previous mapping efforts); see also Howard Kunreuther and Marilyn Montgomery, The Importance of Accurate Flood Hazard Maps and Risk-Based Premiums, Wharton Sch. (Mar. 28, 2018), <https://riskcenter.wharton.upenn.edu/resilience-lab-notes/importance-accurate-flood-hazard-maps-risk-based-premiums/>.) it is not universally shared and is prone to disagreements on occasion. (See Jake Varn, Let's Start with Better Floodplain Maps, Bipartisan Pol'y Ctr. (Nov. 8, 2017), <https://bipartisanpolicy.org/blog/lets-start-with-better-floodplain-maps/> (asserting that the FEMA maps are a hodgepodge of data collected between 1900 and 1960 and the product of a 1973 compromise between the Army Corps of Engineers' strict standards and more lax local policies); Ramin Skibba, Why Are FEMA's Flood Maps So Horribly Flawed? Slate (Sept. 6, 2017), <https://slate.com/technology/2017/09/heres-why-femas-flood-maps-are-so-terrible.html> (suggesting that FEMA maps do not calculate for climate change, are expensive to maintain in the face of other changing inputs, and can be manipulated by local governments); Joel Scata, FEMA's Outdated and Backward-Looking Flood Maps, Nat. Resources Def. Council (Oct. 12, 2017), <https://www.nrdc.org/experts/joel-scata/femas-outdated-and-backward-looking-flood-maps> (suggesting that 58% of FEMA maps are out of date and do not account for anticipated future events, such as changes in rainfall patterns and other incidents of climate change). In addition, because the maps focus on existing conditions, they do not account for such things as channel migration.) Nevertheless, these maps provide a national perspective on riverine and coastal flood management.

Despite NFIP participation by most coastal jurisdictions, coastal flooding hazards are becoming less predictable. While the USGS is experimenting with data collection, (See Surge, Wave, and Tide Hydrodynamics (SWaTH) Network, U.S. Geological Surv. (Feb. 10, 2016), https://www.usgs.gov/mission-areas/water-resources/science/surge-wave-and-tide-hydrodynamics-swath-network?qt-science_center_objects=0#qt-science_center_objects. The USGS's SWaTH system was deployed along the Atlantic Coastline of the Continental United States following Hurricane Sandy to "enable scientists to measure and analyze wave height, frequency, and devolution as functions of water depth and distance inland—important factors that dramatically influence storm-tide damage." Coastal Storm Response Surge, Wave, and Tide Hydrodynamics Network (SWaTH), U.S. Geological Surv. (Aug. 26, 2019), <https://www.sciencebase.gov/catalog/item/560aa95ce4b058f706e-5374b>; see also Coastal Flood Exposure Mapper, Digital Coast, <https://coast.noaa.gov/digitalcoast/tools/flood-exposure.html> (last visited Oct. 19, 2019).) predictions are more difficult for this phenomenon due to its multifarious causes, many of which relate to climate change: rising sea levels (especially for small island nations), high tides and storm surges, higher temperatures, melting ice caps, the impact of

El Nino and La Nina on weather patterns, and humankind's obsessive desire to locate vulnerable land uses in flood-prone coastal areas. (See Coastal Flooding, ScienceDirect, <https://www.sciencedirect.com/topics/earth-and-planetary-sciences/coastal-flooding> (last visited Oct. 12, 2019) (listing articles on the causes of coastal flooding).) Despite this lack of predictability, we know that persistent sea rise threatens low-lying areas such as the City of Miami, (The City of Miami projects that, by 2030, sea level will have risen 6 to 10 inches above the 1992 mean sea level and that, by 2060, it will have risen 14 to 34 inches above that level, inundating lower-lying roads and land uses. See Miami's Vulnerability to Flooding, City of Miami, <https://www.miamigov.com/Government/ClimateReadyMiami/Flooding> (last visited Oct. 12, 2019); see also Miami Underwater?, Nat'l Geographic, <https://www.nationalgeographic.com.au/videos/explorer-bill-nyes-global-melt-down/miami-underwater-3669.aspx> (last visited Oct. 12, 2019).) as evidenced by the harsh impacts of Hurricane Katrina on New Orleans and Superstorm Sandy on the Eastern Seaboard. (See Sara Gibbens, Hurricane Sandy, Explained, Nat'l Geographic (Feb. 11, 2019), <https://www.nationalgeographic.com/environment/natural-disasters/reference/hurricane-sandy/> (setting out the human and property costs of Hurricane Sandy and suggesting that many similar events will occur as a result of climate change); see also Hurricane Sandy - New York, U.S. Geological Surv., https://www.usgs.gov/centers/ny-water/science/hurricane-sandy-new-york?qt-science_center_objects=0#qt-science_center_objects (last visited Oct. 12, 2019).) As coastal flooding becomes increasingly persistent, caution counsels against further development on vulnerable seafronts.

Earthquakes and Tsunamis

At present, there is no scientifically accepted method of predicting the exact time, place, or magnitude of earthquakes and resulting tsunamis. (See Can You Predict Earthquakes?, U.S. Geological Surv., https://www.usgs.gov/faqs/can-you-predict-earthquakes?qt-news_science_products=0#qt-news_science_products (last visited Oct. 12, 2019). The academic community appears to agree with this conclusion. See Yan Y. Kagan, Are Earthquakes Predictable?, 131 Geophysical J. Int'l 505, 506, 523 (1997) (concluding that such predictability is an "open problem" and surveying literature on the issue). With tsunamis, it is obviously better to factor in distance so that the availability of additional time makes it more likely that harm will be avoided or alleviated.) As a result, scientists have focused instead on the areas that are most prone to these phenomena. Since approximately 80% of earthquakes occur along the Pacific Rim, many seismologists advocate using data to enact responsive building codes, propose tsunami inundation zones, and ensure adequate insurance ratings, rather than await the "silver bullet" of exact predictions that may never fully develop. (See Robert Lamb, Will Earthquakes Ever Be Predictable?, HowStuffWorks.com (June 14, 2010), science.howstuffworks.com/nature/natural-disasters/earthquake-predictable.htm; see also Can We Predict Earthquakes?, Planet Sci., <http://www.planet-science.com/categories/over-11s/natural-world/2011/03/can-we-predict->

[earthquakes.aspx](#) (last visited Oct. 12, 2019) (asserting that there is a 67% chance that an earthquake will strike the San Francisco Bay area within the next 30 years.)

Coastal Erosion

The force of waves pounding on coastal rocks, changing them into pebbles, and later changing pebbles into sand, which may be borne away, can change the shape of entire coastlines. (See Erosion, Nat'l Geographic, <https://www.nationalgeographic.org/encyclopedia/erosion/> (last visited Oct. 12, 2019); see also What is Shoreline Erosion?, Am. Geosciences Inst., <https://www.americangeosciences.org/education/k5geosource/content/rocks/what-is-shoreline-erosion>.) Moreover, its adverse effects change with location – hurricanes on the Atlantic Coast pose different risks than extratropical storms on the Pacific Coast, and all coastlines are affected by winter storms. (See National Assessment of Storm-Induced Coastal Change Hazards, U.S. Geological Surv., https://www.usgs.gov/centers/spcmsc/science/national-assessment-storm-induced-coastal-change-hazards?qt-science_center_objects=0#qt-science_center_objects (last visited Oct. 12, 2019); see also National Assessment of Coastal Change Hazards, U.S. Geological Surv., https://www.usgs.gov/natural-hazards/coastal-marine-hazards-and-resources/science/national-assessment-coastal-change-hazards?qt-science_center_objects=0#qt-science_center_objects (last visited Oct 12, 2019) (noting research “to identify areas that are most vulnerable to coastal change hazards including beach and dune erosion, long-term shoreline change, and sea-level rise”). The USGS has predicted that sea level rise will dramatically accelerate the ongoing loss of coastal cliffs in Southern California. See Sea Level Rise Could Double Erosion Rates of Southern California Coastal Cliffs, U.S. Geological Surv. (July 9, 2018), <https://www.usgs.gov/news/sea-level-rise-could-double-erosion-rates-southern-california-coastal-cliffs>.) Due to its highly localized nature, not to mention factors related to climate change, coastal erosion is difficult to predict. Indeed, the best that we might hope for is an assessment of coastal vulnerabilities. (See Coastal Erosion, U.S. Climate Resilience Toolkit, <https://toolkit.climate.gov/topics/coastal-flood-risk/coastal-erosion> (last updated Sept. 13, 2019). (“Sea level rise will cause an increase in coastal erosion and the human response will be critical. If we choose to build hard structures in an attempt to keep the shoreline position stable, we will lose beach area due to scour. If we let the shoreline migrate naturally, we can expect to see erosion rates increase, especially in regions of the coast that are already dealing with starved sediment budgets and rapid shoreline migration.”).) The most frequent land use conflict in this context is the use of physically protective structures such as seawalls, groins, riprap, and levees – practices that are extremely expensive and have had overall negative effects (See id. These solutions have been discounted due to their prohibition under state and local regulations, erosive impacts on beaches and dunes, diversion of stormwater and waves onto other properties, and installation and

maintenance costs.) and which are further dealt with below. (See infra discussion of Rockaway Beach, Oregon, under section “[Coastal Vacation Home](#)” below.)

Landslides

As with previous examples of natural hazards, the incidence, force, and impacts of landslides are not precisely predictable; however, to a great extent, their probabilities are. We do have some knowledge about landslides – their types, elements, triggering mechanisms (especially the interaction of water with unstable rock and soil and the impacts of earthquakes and volcanic activity), mapping, remote sensing, and monitoring. (See Lynn M. Highland & Peter Bobrowsky, U.S. Dep’t of the Interior, U.S. Geological Survey, *The Landslide Handbook: A Guide to Understanding Landslides*, https://pubs.usgs.gov/circ/1325/pdf/C1325_508.pdf (compiling data, research projects, and recommendations for dealing with landslides).) With available tools, we often have sufficient information to assess landslide probabilities in order to fashion regulations to mitigate or negate their impacts through avoidance or responsive building codes. (See, e.g., Predicting Landslide Hazards in Near Real-Time, Earth Observatory (Apr. 18, 2018), <https://earthobservatory.nasa.gov/images/92018/predicting-landslide-hazards-in-near-real-time> (announcing the development of the Landslide Hazard Assessment for Situational Awareness (LHASA) model, which utilizes space-based observations to estimate landslide potential on a global scale); Byung-Gon Chae et al., Landslide Prediction, Monitoring and Early Warning: A Concise Review of State-of-the Art, 21 Geosciences J. 1033 (2017), https://www.researchgate.net/publication/321654509_Landslide_prediction_monitoring_and_early_warning_a_concise_review_of_state-of-the-art (reviewing literature on the subject); Emanuele Intrieri & Giovanni Gigli, Landslide Forecasting and Factors Influencing Predictability, 16 Nat. Hazards & Earth Sys. Sci. 2501 (2016), <https://www.nat-hazards-earth-syst-sci.net/16/2501/2016/>.)

Wildfires

This term includes forest, vegetation, and grass fires in dry circumstances. While it usually denotes uncontrolled fires in forests or wildland areas, wildfires can also consume houses and agricultural resources. (See Wildfire, ScienceDaily, <https://www.sciencedaily.com/terms/wildfire.htm> (last visited Oct. 12, 2019). While the public’s attention has largely focused on loss of life and damage to property, the media and government often ignore the broader impacts of wildfires on the environment. Wildfire is now the biggest factor in the loss of older forest on federal lands and reduced northern spotted owl habitat. See personal communication from Ted Lorenzen to author (Oct. 18, 2019) (on file with author).) Wildfires need a fuel source (the greater the load, the more intense the fire), air (oxygen and winds), and an

ignition source – whether natural in origin (e.g., lightning) or through human sources (as is more often the case at the national level). (Unlike for landslides and floods, there is a suppression system in place for wildfires on which states have relied. Unfortunately, increasing expenditures on fire suppression is no longer effective. See The 2018–19 Budget: Fire Recovery Proposals, Cal. Legis. Analyst's Off., <https://lao.ca.gov/Publications/Report/3767> (last visited Oct. 19, 2019). The amount of resources allocated to fuel modification is proportionately paltry, and administrative inefficiencies have truncated success. See personal communication from Ted Lorenzen to author (Oct. 18, 2019) (on file with author).) They are most common in the American West, where heat, drought, and both natural and human fire sources are prevalent. (See Claire Wolters, Climate 101: Wildfires, Nat'l Geographic (Aug. 9, 2019), <https://www.nationalgeographic.com/environment/natural-disasters/wild-fires/>.) These combinations are capable of mapping, (See Nat'l Interagency Fire Ctr. et al., North American Seasonal Fire Assessment and Outlook (2019), https://www.predictiveservices.nifc.gov/outlooks/NA_Outlook.pdf; North American Fire Danger, Wildland Fire Assessment Sys., <https://www.wfas.net/index.php/fire-danger-rating-fire-potential%2D%2Ddanger-32/north-america-fire-danger-map> (last visited Oct. 12, 2019); Predictive Servs. & Nat'l Interagency Fire Ctr., National Significant Wildland Fire Potential Outlook (2019) https://www.predictiveservices.nifc.gov/outlooks/monthly_seasonal_outlook.pdf (gauging wildland fire danger through assessments of climate, weather, fuel loads, fire danger, and fire activities and through coordination with state, local, and other federal agencies at the National Interagency Fire Center in Boise, Idaho, and ten regional centers).) but the hazard itself is more amenable to probabilistic analysis than precise prediction. (See Probability of Wildfire, Climate.gov, <https://www.climate.gov/maps-data/data-snapshots/data-source-probability-wildfire> (last visited Oct. 12, 2019) (using continuous data streams to predict wildfire probabilities); Patricia Andrews et al., Predicting Wildfires, Sci. Am., Aug. 2007, at 48, https://www.fs.fed.us/rm/pubs_other/rmrs_2007_andrews_p001.pdf; Haiganoush K. Preisler et al., Near-Term Probabilistic Forecast of Significant Wildfire Events for the Western United States, 25 Int'l J. Wildland Fire 1169 (2016), <https://www.fs.usda.gov/treeresearch/pubs/53305>; Jeremy S. Fried et al., Analysing Initial Attack on Wildland Fires Using Stochastic Simulation, 15 Int'l J. Wildland Fire 135 (2006), <https://www.fs.usda.gov/treeresearch/pubs/24567>.)

The common theme in this catalog of potential disasters is that, while we may not know the date or hour of their occurrence, watchfulness is necessary in order to avoid or mitigate their impacts.

Real-Time Dilemmas for Planning Officials

In this section, we examine five proposed developments in areas that present some statistical vulnerability to one or more of the foregoing natural hazards.

Dwelling in a Floodplain

Floodplain mapping is a common feature of American land use planning and regulation. (Omitted from this discussion is the issue of risk evaluation and its impact on flood insurance premiums under federal flood insurance programs.) Most floodplain mapping is undertaken as part of the National Flood Insurance Program (NFIP). Landowners in participating jurisdictions are eligible to purchase NFIP flood insurance for lawfully constructed residences. (See Floodplain Management Requirements, Fed. Emergency Mgmt. Admin., <https://www.fema.gov/floodplain-management-requirements> (last updated July 24, 2019) (explaining the framework under which the federal government designates 100- and 500-year floodplains [i.e., lands with a 1% and 0.2% chance of being flooded over those respective time periods], the restrictions that local governments can impose on construction in those areas, and the system of federally subsidized insurance for residences in those areas.) Such insurance is required for dwellings located in floodplains that are subject to federally backed mortgages. (Under federal law, the purchase of flood insurance is mandatory for all federal or federally related financial assistance for the acquisition and/or construction of buildings in high-risk Special Flood Hazard Areas (SFHAs). If the property is not in an SFHA, but instead in a moderate- to low-risk area, federal law does not require flood insurance; however, lenders can still require it. If, during the life of the loan, FEMA's maps are revised and the property is incorporated into an SFHA, the lender must notify the landowner of their obligation to purchase flood insurance. See Mortgage Lender Requiring Flood Insurance, Fed. Emergency Mgmt. Admin., <https://www.fema.gov/faq-details/Mortgage-Lender-Requiring-Flood-Insurance> (last updated Sept. 26, 2019).)

In theory at least, this kind of development involves elevating or otherwise protecting residential structures that are located within the designated floodplain and therefore at greater risk of being flooded. (Fed. Emergency Mgmt. Admin., National Flood Insurance Program: Floodplain Management Requirements (2005), https://www.fema.gov/media-library-data/1481032638839-48ec3cc10cf-62a791ab44ecc0d49006e/FEMA_480_Complete_reduced_v7.pdf) Nonresidential structures in the floodplain must also be flood-proofed or elevated to avoid problems associated with flooding. (See Floodproofing, Fed. Emergency Mgmt. Admin., <https://www.fema.gov/floodproofing> (last updated Sept. 24, 2019).) Even under the NFIP, however, concerns remain regarding the accuracy of FEMA's maps against the background of climate change, local application and enforcement, uninsured structures, and liability for either the grant or denial of permits for structures in the floodplain. (See Jon A. Kusler, Ass'n of State Floodplain Managers, No Adverse Impact: Floodplain Management and the Courts (2004), https://www.floods.org/NoAdverseImpact/NAI_AND_THE_COURTS.pdf (regarding permit appeals); see also James Schwab et al., Am. Planning Ass'n, Subdivision Design and Flood Hazard Areas (2016), <https://www.planning.org/publications/report/9112664/>. Liability may also attach for negligence in preparing or approving development applications that result in flood damage. See Hutcheson v. City of Keizer, 8 P.3d 1010 (Or. Ct. App. 2000) (imposing liability for subdivision approval where flooding

occurred); Jon Kusler, Ass'n of State Floodplain Managers, Professional Liability for Construction in Flood Hazard Areas (2007), https://www.floods.org/PDF/ASFPM_Professional_Liability_Construction.pdf.)

Industrial Facility at or near a Seismic Fault

Actual and potential earthquake zones are particularly common in the Western United States – especially around the San Andreas Fault in and near the crowded metropolises of Los Angeles and San Francisco. (See David K. Lynch, The San Andreas Fault, [Geology.com](https://geology.com/articles/san-andreas-fault.shtml), <https://geology.com/articles/san-andreas-fault.shtml> (last visited Oct. 13, 2019); Jasmine Aguilera, Two Big Earthquakes Shook Rural Southern California. What Would Have Happened If They Hit a Major City?, Time, July 8, 2019 <https://time.com/5622301/two-big-earthquakes-california-san-francisco-los-angeles/>.) While the near certainty of earthquake activity in these areas has not stopped all development, it has informed local governments as they enact and administer building codes or otherwise regulate that development. (This issue was nearly raised in San Diego Gas & Electric Co. v. City of San Diego, 450 U.S. 621 (1981). There, due to earthquake hazards, the city “downzoned” land that had once been planned for a nuclear power facility to allow for open space and other low-intensity uses. Although the Supreme Court never reached the land-owner’s takings claim, significant land use changes based on natural hazards are likely to see similar challenges in the future (such as challenges to the quality of the information relied on to support the changes). See Jonathan B. Sallet, The Problem of Municipal Liability for Zoning and Land-Use Regulation, 31 Cath. U. L. Rev. 465 (1982).) As such, those areas have walked a tightrope in managing land uses.

Coastal Vacation Home

A recent Oregon case demonstrates the difficulties of building in coastal areas. There, a landowner obtained a permit to construct a beachfront home behind the building line, which was mistakenly set by city officials and only discovered after construction was complete. (See Cody Mann, Rockaway Beach Riprap Saga Continues; \$1.8M Lawsuit Filed, Tillamook Headlight Herald, Apr. 4, 2019, https://www.tillamookheadlightherald.com/news_paid/rockaway-beach-riprap-saga-continues-m-lawsuit-filed/article_9c14615a-5751-11e9-93a1-177a7ad3ff07.html; Aimee Green, Decks Now Collapsing on Oregon Beach House at Center of Riprap Battle, [OregonLive.com](https://www.oregonlive.com/pacific-northwest-news/2018/04/saga_to_save_oregon_beach_hous.html), https://www.oregonlive.com/pacific-northwest-news/2018/04/saga_to_save_oregon_beach_hous.html (last visited Oct. 13, 2019); Troy McMullen, Once Prized and Profitable, Beachfront Real Estate Can Now Be a Losing Proposition, Wash. Post, Aug. 9, 2018, https://beta.washingtonpost.com/realestate/once-prized-and-profitable-beachfront-real-estate-can-now-be-a-losing-proposition/2018/08/07/9757b248-7efd-11e8-b660-4d0f9f0351f_story.html.)

When the home began collapsing, the city refused to authorize the installation of

riprap to shore it up. The landowner sued, and the city (and the State Parks and Recreation Department, which manages the state's coastal interests) was ultimately required to both authorize the installation of riprap and pay the landowner's attorney fees and costs. In addition, the city now faces another lawsuit involving takings and racial discrimination claims. This case illustrates the difficulties that can result from applying anything less than the best available information in the permit application process.

Community in a Landslide-Prone Area

Assuming a building is otherwise allowed under existing regulations, the permitting process may still raise liability concerns. On March 22, 2014, a landslide in Steelhead Haven, near Oso, Washington – on a mountainside saturated by rainwater – killed 43 people. Today, legal proceedings dealing with fault and damages are still pending. (The propensity for landslides was known, but development was allowed to proceed nonetheless. See Joseph Wartman, What We've Learned from the Deadly Oso, Washington Landslide Two Years On, Conversation, Mar. 21, 2016, <https://theconversation.com/what-weve-learned-from-the-deadly-osو-washington-landslide-two-years-on-56528> (concluding that the courts must sort out any liabilities); see also Vince Stricherz, Oso Disaster Had Roots in Earlier Landslides, U. Wash. (July 22, 2014), <https://www.washington.edu/news/2014/07/22/osو-disaster-had-its-roots-in-earlier-landslides/>; Mike Baker & Ken Armstrong, Oso Neighborhood Never Should Have Been Built, Seattle Times, June 7, 2014, http://old.seattletimes.com/html/localnews/2023794966_landslidehistoryxml.html.) The incident raises the question of whether state and local governments have a duty to inquire further about the risk of landslides within their jurisdictions, and amend their regulations accordingly, or whether landowners assume all the risk of development. (As discussed below, Oregon's planning program rarely requires local governments to reevaluate their plans and regulations and, since 2001, imposes no obligation on them to address natural hazards unless the state's Department of Land Conservation and Development (DLCD) provides notice of new hazard information, which has not yet occurred. See infra discussion of Oregon's Goal 7, below.)

Dwelling on Forestland

Landowners often seek to construct dwellings in forested areas so as to take advantage of rural amenities and low taxes. The downside is a lack of public safety resources, particularly fire suppression. (See Howard E. Moore, U.S. Dep't of Agric., U.S. Forest Serv., Protecting Residences from Wildfires: A Guide for Homeowners, Lawmakers, and Planners (1981), https://www.fs.fed.us/psw/publications/documents/psw_gtr050/psw_gtr050.pdf; Or. Dep't of Forestry, Considerations for the Siting of Dwellings on Forest Land (1991), <https://www.oregon.gov/ODF/Documents/AboutODF/LandUsePlanningNote2DwellingSiting.pdf> (pointing out

the dangers of locating dwellings in fire-prone forests and discussing efforts to deal with the same); see also F.C. Dennis, Colo. State Univ. Extension, Forest Home Fire Safety (2012), <https://extension.colostate.edu/docs/pubs/natres/06304.pdf>.) In these situations, the political and legal opprobrium of denying landowners the ability to construct homes on their land, (While the US Supreme Court has noted that personal property may be the subject of rigorous regulation, it has added that:

In the case of land . . . we think the notion . . . that title is somehow held subject to the “implied limitation” that the State may subsequently eliminate all economically valuable use is inconsistent with the historical compact recorded in the Takings Clause that has become part of our constitutional culture.

Lucas v. S.C. Coastal Council, 505 U.S. 1003, 1028 (1992) (Scalia, J.) the likely but indefinite nature of the danger, and the fear of liability combine to make outright denial a more difficult proposition.

The Oregon Approach

Oregon’s planning program combines a system of mandatory, binding local comprehensive plans that control local land use regulations and actions with state policy direction in the form of binding state policies or “goals.” (See generally Edward J. Sullivan, *The Quiet Revolution Goes West: The Oregon Planning Program 1961–2011*, 45 J. Marshall L. Rev. 357 (2012).) One of these binding policies is Goal 7 (Areas Subject to Natural Hazards), (See Or. Admin. R. § 660-015-0000(7); Oregon’s Natural Hazards, Or. Dep’t Land Conservation & Dev., <https://www.oregon.gov/lcd/NH/Pages/Natural-Hazards.aspx> (last visited Oct. 19, 2019); Natural Hazards Mitigation Planning, Or. Dep’t Land Conservation & Dev, <https://www.oregon.gov/lcd/NH/Pages/Mitigation-Planning.aspx> (last visited Oct. 19, 2019).) the purpose of which is “[t]o protect people and property from natural hazards.” (Or. Dep’t of Land Conservation & Dev., Goal 7: Areas Subject to Natural Hazards 1 (2001), <https://www.oregon.gov/lcd/OP/Documents/goal7.pdf> [hereinafter Goal 7].) The goal has four parts, in addition to numerous nonbinding guidelines:

1. Natural hazard planning – local governments must adopt comprehensive plans that reduce risk to people and property from natural hazards (i.e., flooding, landslides, earthquakes, tsunamis, coastal erosion, and wildfires). (See id. Coastal and Western Oregon is within the Cascadia Subduction Zone, a 600-mile fault that runs from northern California up to British Columbia, is about 70–100 miles off the Pacific coast shoreline, and is overdue for “the big one.” See Cascadia Subduction Zone, Or. Office Emergency Mgmt., <https://www.oregon.gov/oem/hazardsprep/Pages/Cascadia-Subduction-Zone.aspx> (last visited Oct. 13, 2019). Coastal areas in particular are at a significant tsunami risk. See Kathryn Schulz, Oregon’s Tsunami Risk: Between the Devil and the Deep Blue Sea, *New Yorker*, July 1, 2019, <https://www.newyorker.com/news/news-desk/oregons-tsunami-risk-between-the-devil-and-the-deep-blue-sea>. For its part, Oregon has taken steps to prepare for such risks. See Or. Seismic Safety Policy

Advisory Comm'n, The Oregon Resilience Plan: Reducing Risk and Improving Recovery for the Next Cascadia Earthquake and Tsunami (2013),

2. https://www.oregon.gov/oem/Documents/Oregon_Resilience_Plan_Final.pdf; see also Michael J. Rupp, Is Western Oregon Ready for the Big One? (PowerPoint presentation on file with author) (describing the impacts of an overdue earthquake and tsunami on Oregon and measures to deal with the same); Kathryn Schulz, The Really Big One, New Yorker, July 13, 2015, <https://www.newyorker.com/magazine/2015/07/20/the-really-big-one> (same). The Oregon Department of Geology and Mineral Industries has compiled digital maps showing where landslides have occurred or are likely to occur. See SLIDO: Statewide Landslide Information Layer for Oregon, Or. Dep't Geology & Min. Industries, <https://gis.dogami.oregon.gov/maps/slido/> (last visited Oct. 19, 2019). As discussed below, there is generally no requirement that local governments update natural hazard information unless DLCD requires it – something which, as of the date of this article, DLCD had not done since that requirement was first adopted in 2001.
3. New hazard information – the state's Department of Land Conservation and Development (DLCD) must consult with state and local representatives and review new hazard information provided by federal and state agencies. If DLCD believes local governments should respond to that information, it must notify them and allow them at least 36 months to do so.
4. Implementation – on receiving such notice, local governments must evaluate the new information in terms of risk to people and property (The goal sets forth certain assessment standards, namely:
 - a. The frequency, severity and location of the hazard;
 - b. The effects of the hazard on existing and future development;
 - c. The potential for development in the hazard area to increase the frequency and severity of the hazard; and
 - d. The types and intensities of land uses to be allowed in the hazard area.
5. Following comment and further evaluation, the local government will then incorporate such information into their comprehensive plans and implementing measures in accordance with certain risk management principles. (These include:
 - a. Avoiding development in hazard areas where the risk to people and property cannot be mitigated
 - b. Prohibiting the siting of certain essential facilities, major structures, hazardous facilities and special occupancy structures . . . in identified hazard areas, where the risk to public safety cannot be mitigated, unless an essential facility is needed within a hazard area in order to provide essential emergency response services in a timely manner.
6. Local governments are deemed in compliance with Goal 7's provisions relating to coastal and riverine flood hazards if they adopt and implement floodplain regulations that meet the minimum NFIP requirements. See Goal 7, *supra* note 47, at 1–2. The Oregon Department of Land Conservation and Development (LCDC) has addressed natural hazards through other goals, as well, such as by

- establishing siting and fire safety standards for dwellings and other structures in forest zones under Goal 4 (Forest Lands) in order to mitigate the risks associated with wildfires. See Or. Admin. R. § 660-006-0029, and -0035-0040.)
7. Coordination – finally, state agencies must coordinate their disaster management programs with those of local governments and provide local governments with information and technical assistance. (As Goal 7 itself notes, such cooperation and coordination is also required under Or. Rev. Stat. § 197.180 and Goal 2 (Land Use Planning).)

This goal was adopted in 1974 (Goal 7, along with thirteen others, became effective in January of 1975. See LCD 1, filed Dec. 31, 1974, effective Jan. 25, 1975.) and has since undergone only one substantial revision, in 2001. The deficiencies of the original version, (The original proposal, then numbered as Goal 5, provided:

Areas Subject to Floods, Landslides & Other Natural Hazards

Development subject to damage or which could result in loss of life within the state, both public and private, shall not be located in known areas of natural hazards in order to protect life and property.

DEFINITIONS

Natural Hazardous Areas – Areas that are subject to natural events that can result in death or endanger the works of man.

Development – Means the performance of any building or mining operation, the making of any material change in the use or appearance of any structure or land, the division of land, or the creation or termination of rights of access.

LCDC Complete Public Hearings Binder, Comments to LCDC on Nov. 25, 1974, at 160 (on file with author).

In late 1974, LCDC responded to public comments in adopting the final version of the renumbered Goal 7:

To protect life and property from natural disasters and hazards.

Developments subject to damage or that could result in loss of life shall not be planned nor located in known areas of natural disasters and hazards without appropriate safeguards. Plans shall be based on an inventory of known areas of natural disaster and hazards.

Areas of Natural Disasters and Hazards - are areas that are subject to natural events that are known to result in death or endanger the works of man, such as stream flooding, ocean flooding, ground water, erosion and deposition, landslides, earthquakes, weak foundation soils and other hazards unique to local or regional areas.

LCD 1, filed Dec. 31, 1974, effective Jan. 25, 1975.) which lacked sufficient definitions, prohibited development in “known” hazard areas, and did not provide for natural hazard inventories (thus raising the specter of local government liability), were corrected during the public hearings process. (Public hearings on the first 14 goals were held on November 19 and December 13, 1974, resulting in their revision and eventual adoption on December 31, 1974. See Statewide Goal Hearing Binders (on file with author).) The resulting version was more efficient – albeit limited, cautious, and ad hoc in its effects – requiring response only to known

dangers. (Michael Rupp, a current FEMA and former DLCD employee who dealt with the adoption and implementation of Goal 7, has observed that:

Goal 7 was one goal that suffered from the lack of scientific evidence that could support comprehensive measures to protect or mitigate from the effects of natural disasters. As jurisdictions proceeded with complying with the Statewide Planning Goals through the development of their comprehensive plans and implementing measures, information on Oregon's natural hazards was lacking other than floodplain maps prepared by the National Flood Insurance Program.

Personal communication from Michael Rupp to author (Sept. 9, 2019) (on file with author). By 1986, all local comprehensive plans in Oregon were "acknowledged" as complying with the goals. Under the original 1973 legislation establishing the Oregon planning program, comprehensive plans would have been updated periodically thereafter. However, due to the time, expense, and local resistance to periodic review, that requirement was virtually eliminated in most parts of the state. The demise of periodic review has harmed the Oregon planning program in that comprehensive plans are updated with respect to Goal 7 only if DLCD provides notice or local governments act voluntarily. There is no general obligation for local governments to update their comprehensive plans in the face of new hazard information without notice from DLCD. Another substantial obstacle to the update of comprehensive plans is the "unfunded mandates" provision of the Oregon Constitution, which generally prohibits the state from imposing new programs on local governments without also providing the requisite funds. See Or. Const. art. XI, § 15.)

The 2001 revisions to Goal 7 were made in response to a gubernatorial executive order following a series of natural disasters in 1996 and 1997. The executive order called for a review of the goal itself, an examination of the hazard planning process in Oregon, an evaluation of how effectively the goal was implemented at the local level, and recommendations on how it could be better stated and applied throughout the state. (See Univ. of Or. Dep't of Planning, Public Policy & Mgmt. & Or. Dep't of Land Conservation & Dev., Implementation of Goal 7: An Evaluation and Discussion of Hazard Planning in Oregon 1 (1998) (on file with author) (concluding that the original version of Goal 7 was vague, inconsistently applied, and, with little state direction, difficult to implement and noting there was little information, expertise, funding, and, with the demise of periodic review, incentive for local governments to update their comprehensive plans). Other state agencies ramped up their responses to natural hazards after the series of 1996 disasters. See Or. Dep't of Forestry, Forestry, Landslides and Public Safety (2001), <https://www.oregon.gov/ODF/Documents/WorkingForests/landslidespublicsafety.pdf> (emphasizing probabilism, the need for research and information sharing, the impact of forest practices on other uses, and the role of planning and regulation to avoid land use conflicts and natural hazards).) The result was a shift away from the "known hazards" and "appropriate safeguards" approach to one that triggered local responses only if DLCD gave local governments notice of such hazards, based on its own evaluation of relevant information. (The 1998 report evaluating the original version of the goal, comments on the same, a draft of the revised goal, and the final revised version are on file with DLCD and the author. The impacts of these changes are apparent in Southern Oregon Pipeline

Project, Inc. v. Coos County, 57 Or. LUBA 44, 71–72 (2008).) This approach mollified local governments, as it put the burden on DLCD to impose any local obligations. Of course, such impositions by DLCD will likely still raise local government hackles, especially as to funding the planning and regulatory responses to the new hazards. (The state governments in Oregon and Washington recently published a report containing extensive information and resources for mapping and responding to landslides. See Wash. Geological Survey & Or. Dep’t of Geology & Mineral Indus., Homeowner’s Guide to Landslides for Washington and Oregon (2017), <https://digital.osl.state.or.us/islandora/object/osl:83498>. However, DLCD has not yet required that local governments in Oregon respond to these hazards.)

There has been remarkably little litigation involving Goal 7, much of which has dealt with the need for or adequacy of local government findings. (Findings are especially important in addressing Goal 7 and other goals relating to natural hazards. See Save Our Rural Or. v. Energy Facilities Siting Council, 121 P.3d 1141, 1158–59 (Or. 2005); City of West Linn v. Land Conservation & Dev. Comm’n, 119 P.3d 285, 294 (Or. Ct. App. 2005); Stevens v. City of Cannon Beach, 854 P.2d 449, 459–60 (Or. 1993); Norvell v. Portland Metro. Area Local Gov’t Boundary Review Comm’n, 604 P.2d 896, 900 (Or. Ct. App. 1979). Similarly, goals relating to natural hazards do not apply to actions that do not involve “development.” Or. Shores Conservation Coal. v. Lincoln Cty., 36 Or. LUBA 288, 314 (1999).) Other cases have turned on the allocation of responsibilities between state and local governments in addressing natural hazards, (See S. Or. Pipeline Project, Inc. v. Coos Cty., 57 Or. LUBA 44, 71–72 (2008) (holding that the county was not obligated to respond to tsunami information absent notice by DLCD to consider the same).) while still others have dealt with the applicability of Goal 7 where other goals conflict. (See Home Builders Ass’n of Lane Cty. v. City of Eugene, 41 Or. LUBA 370, 442–43 (2002) (holding that the city could not impose a discretionary geotechnical analysis obligation under Goal 7 on “needed housing,” which is exempt from discretionary standards under Goal 10 and other provisions of Oregon law). Coastal areas are subject to differently worded natural hazard protections than those under Goal 7. See Columbia Riverkeeper v. Clatsop Cty., 243 P.3d 82, 96 (Or. Ct. App. 2010); Borton v. Coos Cty., 52 Or. LUBA 46, 58–60 (2006); Edward J. Sullivan, Land Use Conflict Management in Beaches and Dunes Areas, 55 Willamette L. Rev. 93 (2019); Edward J. Sullivan, Shorelands Protection in Oregon, 33 J. Envtl. L. & Litig. 129 (2018). The real estate values inherent in coastal development sometimes conflict with regulatory schemes, causing controversy. Recently, the Governor of Oregon approved legislation repealing the state Department of Geology and Mineral Industries’ authority to prohibit construction in tsunami inundation zones, leaving that task to local governments, while simultaneously proposing new Oregon Structural Specialty Code standards in such zones, namely, the 2016 edition of the American Society of Civil Engineers’ Minimum Design Loads and Associated Criteria for Buildings and Other Structures (ASCE 7-16). See Act effective January 1, 2020, ch. 502, 2019 Or. Laws _____. The Oregon Seismic Safety Policy Advisory Committee, under the Oregon Office of Emergency Management, has recommended approval of the ASCE 7-16 standards. See 2019 Oregon Structural Specialty Code

Adoption, Or. Building Codes Division, <https://www.oregon.gov/bcd/codes-stand/code-adoption/Pages/2019-osscc-adoption.aspx> (last visited Oct. 14, 2019).) In cases concerning a local government's treatment of a particular hazard, such as floodplains or wildfires, the reviewing bodies have held the local government to the standards of the goal. (See *Jaqua v. City of Springfield*, 46 Or. LUBA 134, 163–64 (2004) (holding that development approval under revised plans that was conditioned on future compliance with city floodplain regulations and backed by a draft floodplain study complied with Goal 7); *Smith v. Douglas Cty.*, 37 Or. LUBA 801, 807–08 (2000) (holding that the imposition of conditions to ensure flood conflict resolution measures, including removal of homes when threatened with flooding, was sufficient under Goal 7); *Johnson v. Jefferson Cty.*, 56 Or. LUBA 25, 50–51 (2008) (holding that conditions requiring development to comply with regulations to mitigate fire risk, supported by testimony of adequacy from local fire protection authority, met Goal 7 requirements); *Johnson v. Jefferson Cty.*, 56 Or. LUBA 72, 108–09 (2008), aff'd, 189 P.3d 34 (Or. Ct. App. 2008) (similar).) Still, the cases involving natural hazards, planning, and land use regulation are remarkably rare compared to those involving governmental liability and insurance claims.

Conclusion

Natural hazard planning, risk evaluation, and consequent land use regulation are politically and fiscally difficult, but, in the long run, those difficulties pale in comparison with failing to undertake such efforts. (John Maynard Keynes' observation that “[i]n the long run we are all dead,” however it was meant, captures the short-term thinking of the political class. John Maynard Keynes, *A Tract on Monetary Reform* 80 (MacMillan & Co. 1924). But for every dollar spent on disaster prevention, there is a savings of 6 dollars. See Laura Lightbody and Matthew Fuchs, Every \$1 Invested in Disaster Mitigation Saves \$6, Pew Charitable Trusts (Jan. 11, 2018), [https://www.pewtrusts.org/en/research-and-analysis/articles/2018/01/11/every-\\$1-invested-in-disaster-mitigation-saves-\\$6](https://www.pewtrusts.org/en/research-and-analysis/articles/2018/01/11/every-$1-invested-in-disaster-mitigation-saves-$6).) The federal government provides some direct assistance for floodplain planning and regulation and indirect assistance for other natural hazard issues (i.e., grants to deal with, *inter alia*, coastal erosion, earthquakes, tsunamis, wildfires on federal lands, and overall hazard mitigation planning). (See *supra* Adam B. Smith, *2018's Billion Dollar Disasters in Context*, Climate.gov (Feb. 7, 2019), <https://www.climate.gov/news-features/blogs/beyond-data/2018s-billion-dollar-disasters-context>.) Some states have programs that provide local governments with similar assistance. However, most of the necessary work falls to local governments to undertake alone. As local governments are historically cash-strapped, this system perpetuates the blame game script that inevitably follows natural disasters, and long-term natural hazard planning often gets short shrift compared to other priorities with prospects for more immediate political gratification.

Outside of floodplain disaster response, where all states are potentially equal, the Oregon planning program works relatively better in that it calls for some state

involvement in natural hazard management instead of a complete delegation of land use controls to local government. Existing comprehensive plans provide the basis for the analysis requirements, standards, conditions, and prohibitions contained in local regulations. The state could require that local governments respond to new hazard information, including those dangers enhanced by climate change, in their planning and land use regulations. Thus, with regard to the natural hazards identified in Part I above, Oregon has in place a structure through which it can mitigate development impacts from those threats. The problem is that it does not exercise all of its powers.

To some extent, then, Oregon's difficulties mirror those of the rest of the nation. While the state has a responsive structure in place, local governments generally do not possess the requisite funds to incorporate new hazard information into their local plan policies and regulations, and the state has proven relatively unwilling to require that local governments take on those costs.

Thus, Oregon is both unique and the same. The state is capable of requiring local governments to meet its standards, but its refusal to do so and its fear of imposing unfunded mandates under Art. XI, § 15 of the Oregon Constitution. Create further obstacles to realizing good public policy in a relatively planning-friendly state.

Unfortunately, avoidance of the long-term costs of planning and regulation – as with any deferred maintenance cost – might well bring short-term political gratification, but it often results in significantly greater costs in the long run. For this reason, enhanced risks in the uncertain face of climate change, records that are often only a century old and therefore serve as inadequate predictors of future natural hazards, and the need for a margin of safety in planning and regulation all require immediate public attention.

Abstract

In recent years, wildfire has become increasingly prominent as a damaging phenomenon in the western portion of the United States. In populated areas, it is a hazard to life and property, and in forested areas it degrades habitat and commercially valuable trees. The increasing risk from wildfire results from a combination of urban-density development adjacent to undeveloped areas, environmental conditions related to climate change, and decades of fire suppression that have allowed the accumulation of burnable fuel. There are multiple options available to address wildfire risk, such as buffer areas around communities; defensible space around structures; fire-resistant building construction; and forestry techniques such as fire suppression, managed burning, controlled burning, and thinning. This chapter describes the geographic and institutional setting of wildfire in the western USA and uses examples of recent fire events to illustrate risk-reducing options, including discussion of differing perspectives on their application.

Climate change · Defensible space · Fire suppression · Prescribed burning · Wildland-urban interface

Introduction

Wildfire has always been present as a feature of the American West. Historically, naturally occurring fires regularly burned portions of forests and grasslands and native peoples used fire to manage land for production of food and craft materials. Beginning in the late nineteenth century, fire suppression was used to protect human communities while fires burned uncontrolled in undeveloped areas (Wagtendonk, 2007). The western portion of the USA is especially susceptible to fire, with low humidity in much of the region and large areas of mountainous terrain, forests, mixed woodlands, and grasslands. Dealing with western wildfires has become more challenging because of “the warming and drying climate, the build-up of fuels, and the expansion of the wildland–urban interface (WUI; the zone where houses meet or intermingle with undeveloped wildland vegetation)” (Schoennagel et al., 2017: 4583).

An important element of wildfire in the western USA is that the pattern of settlement resulted in federal government ownership of significant portions of the landscape. For example, 45.4% of California is federal land, 52.3% of Oregon is federal, and 38.6% of Arizona is federal. These figures contrast with, for example, 1.7% of Indiana, 0.8% of New York, and 1.9% of Texas (Ballotpedia, n.d.). There is more than one way to define which states should be included in the West. Here, we focus on states with a large federal presence and frequent occurrence of wildfire. The US Census Bureau (2021) definition of the West is used, with the adjustment of leaving out Hawaii. Thus, there are 12 Western states for purposes of this discussion: Alaska, Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming.

Because of these large areas of federal land, policy and practice in reducing the risk of damaging wildfires requires taking into account the several federal agencies involved in land management. The two that manage the largest percentage of federal lands in the West are the US Forest Service and the US Bureau of Land Management; the US National Park Service and the US Fish and Wildlife Service also have significant holdings. Wagtendonk (2007: 3) described the evolution of federal wildfire policy over more than a century:

When the Forest Service was established in 1905, fire suppression became its reason for being. . . . Fire suppression was the only fire policy for all federal land management agencies until the late 1960s when the National Park Service officially recognized fire as a natural process. Lightning fires ignited in special management zones in parks were allowed to run their course under prescribed conditions. The Forest Service followed suit in 1974 and changed its policy from fire control to fire management, allowing lightning fires to burn in wilderness areas.

Allowing fires to burn in some locations while suppressing them in most others has provoked policy debates over how to manage public lands in the West. This policy does not adequately address the accumulation of flammable fuels created by exclusion of fire from the landscape, an accumulation that can cause high-severity fires that kill trees and threaten communities. Policy debates about wildfire have become especially relevant in the context of a “megadrought” occurring in the western USA, a long-term period of dry weather that is believed to be the most severe in 1200 years (Hirsh, 2022). Predictably, climate change is thought to be a major contributor to the drought because higher temperatures result in drier air. This creates a context in which “Increasing heat, changing rain and snow patterns, shifts in plant communities, and other climate-related changes have vastly increased the likelihood that fires will start more often and burn more intensely and widely than they have in the past” (Borunda, 2020). Human activity is an aggravating factor, since naturally occurring wildfires are ignited by lightning, while approximately 85% of wildfires in the USA are human-caused, through carelessness, arson, and equipment use and malfunctions (US National Park Service, 2022).

Damaging wildfires have occurred often in the western states over the past several years, building public awareness of the increase in fire risk due to changing environmental conditions. Some of these fires involved fuel accumulation on federal lands, while others did not. In June 2012, the Waldo Canyon fire in Colorado Springs swept through neighborhoods on the western edge of the city, forcing evacuation of tens of thousands of people, destroying 346 houses, and killing two people. Weather conditions at the time included high temperatures and high winds (Encyclopedia staff, 2020). The fire was not especially large, burning over 18,000 acres (approximately 2.47 acres equal one hectare), much of which was national forest land, but the impact on a populated area was notable. In October 2017, the Tubbs fire in Napa and Sonoma counties of northern California made clear the vulnerability of urban areas to wildfires in areas of grass and oak woodland rather than forest, as it moved from dry hills into portions of Santa Rosa and adjoining suburbs, killing 22 people and destroying 5643 structures (Graff, 2018). Media coverage of the Camp Fire in the forested Sierra Nevada foothills of northern California gave the public a dramatic illustration of the dangers of wildfire in an era of climate change. The fire began on the morning of November 8, 2018, and by the next day it had destroyed a community of 27,000 people, killing 85 (National Institute of Standards and Technology, 2021).

The purpose of this chapter is to examine key preventive or risk management options in relation to wildfire in the western USA. Critical fire events can provide an empirical referent for policymakers in evaluating the potential effectiveness of specific options or combinations of options. Four categories of policy options that emerge from examination of wildfire events are the following: buffer areas around communities; defensible space around structures; standards for fire-resistant building construction; and forest management techniques such as fire suppression, managed burning, controlled burning, and thinning. Policy choices about adopting and implementing options depend on location, jurisdiction (federal, state, and local), and in some cases on debates about effectiveness and risk-involving practitioners, researchers, and the public.

Two limitations of this chapter related to research and terminology should be mentioned. First, examples have been chosen to highlight the policy options framework used in the chapter, but they are a small fraction of all wildfires. There are thousands of fires of varying sizes in the West each year; in California alone, in 2021 the statewide fire agency (colloquially, Cal Fire) recorded 8178 fire incidents, 2,496,204 acres burned, and 3560 structures destroyed (California Department of Forestry and Fire Protection, 2022). Second, the term “wildfire” can be somewhat misleading. It may seem to describe only fires that occur in unpopulated areas, burning through largely natural landscapes, but this is true of some wildfires and not others. Wildfires also occur in places exhibiting various combinations of woodland, brush, or grassland adjacent to rural settlements, urban development, or agricultural uses.

A geographic choice made in the scope of the chapter is important as well. Two of the examples of wildfire discussed here occurred in California and one in Southern Oregon, just north of the border with California. California is an integral part of the American West, and it offers a range of examples of the relevant wildfire types and policy options. It also offers graphic, powerful illustrations of the impacts of climate change and geography on the risks and dangers of wildfire in the western states.

The Geography of Western Wildfire

The geographic setting for this examination of wildfire, the western USA, is notable for its scope and variety. It includes temperate coastal rainforest, large areas of inland forest, oak woodland, grassland, desert, and remote wilderness, spreading over many elevations and latitudes. It also includes thousands of cities and small communities, along with sizeable metropolitan areas (all approximate figures) such as the Los Angeles metro with some 13 million residents, the San Francisco Bay Area (eight million), Phoenix, Arizona (five million), Seattle, Washington (four million), and Denver, Colorado (three million).

These metro areas are widely distributed across the West. To people living in other parts of the USA or in other countries, whose impressions of the western USA may be shaped by television and film, it could seem this is mostly an urban landscape that looks like Los Angeles or San Francisco. Instead, it is a complex mixture of urban and rural development, agricultural land, and extensive wildlands. California exemplifies this complexity despite, or perhaps because of, its status as the most heavily populated state in the West. The population of California in 2021 was approximately 39 million people. The population of the second most populous state in the West, Washington, was 7.7 million. Wyoming had the smallest population, with 579,000.

The complexity of California’s landscape becomes apparent with figures on land use in the state. The total acreage of California is 100,206,720. Of this total, 45.4%, or 45,493,133 acres, is land owned by the federal government (Congressional Research Service, 2020), while 34,006,800 acres (33.9%) are in agricultural uses (American Farmland Trust, 2022). This leaves 20,706,787 acres (20.7%) in other

land uses. Most of the federal land in the West consists of forests, grazing land, and national parks, as illustrated by agency holdings in California. The Forest Service in the Department of Agriculture owns 45.7% of the federal land in the state, followed by the Bureau of Land Management (BLM) in the Department of Interior with 33.2%, the National Park Service (16.7%), the Department of Defense (3.7%), and the Fish and Wildlife Service (0.65%) (Congressional Research Service, 2020).

To place the land use figures for California in broader national context, approximately 27% of all land in the USA is owned by the federal government. Total 92% of federal land is located in the 12 western states (Ballotpedia, n.d.), and almost 50% of land in these states is federally owned (Stowell, 2016). A portion of the federal properties in the western states consists of grasslands used for grazing or other purposes rather than forested land; this is especially true in Nevada, where approximately 85 percent of the land is federal (Stowell, 2016).

As a generalization, most of the grazing land is administered by the BLM, while much of the forested land is administered by the Forest Service. The Forest Service owns 166,819,068 acres in the West, 86.5% of its holdings. Almost all BLM land is in the western states, totaling 246,357,526 acres (Stowell, 2016). As is true in California, several other federal agencies own portions of western land, including the Fish and Wildlife Service and the Park Service. Together with the Forest Service and the BLM, these agencies oversee approximately 95% of the federal lands in the USA (Ballotpedia, n.d.).

Mountains are a key element in an examination of wildfire in the West. Many of the large, damaging fires occur either in the pine and fir forests of mountainous areas, or in mountains and hills with combinations of grassland, brush, or oak woodland. Three major mountain ranges traverse the western states in a north-south orientation. On the eastern side of the region, the Rocky Mountains extend from Montana, Idaho, and Wyoming in the north to Colorado and Utah, terminating in south in New Mexico. (A range called the Arizona/New Mexico Mountains lies to the south of the Rockies.) They are separated from the Cascade and Sierra Nevada Mountains to the west by the Columbia Plateau and the Basin and Range Province. The Rockies serve as a geographic dividing line between east and west in the USA, and they also present a key climatic distinction for the study of wildfire. Several hundred miles to the east of the Rockies, the relatively dry climate of the western part of the country transitions to the more humid climate of the eastern states. It is the combination of wildland terrain and vegetation with a dry climate that makes the West so vulnerable to wildfire.

Winter snow and summer thunderstorms are present in the Rockies. Temperatures are quite different from north to south, but a relatively dry climate and summer precipitation are common throughout the range. For example, Missoula, Montana, in the north has mild summers and cold winters, with annual precipitation of 14.1 inches/358 mm (Weatherbase, 2022a). At the southern end of the Rockies, Albuquerque, New Mexico has warm summers and cool winters, with annual precipitation of 9.5 inches/241 mm (Weatherbase, 2022b). In contrast with places farther west, both cities have significant rainfall during the summer months; the wettest month of the year in Missoula is June, and in Albuquerque it is August.

On the western side of the region and inland from the coast, the Cascade Mountains extend from Washington in the north through Oregon, into Northern California. The Cascades transition into the Sierra Nevada Mountains, which reach down the eastern part of California, terminating north of Los Angeles. Unlike the Rockies, which consist of a series of ranges that in places spread east-west over hundreds of miles, the Cascades and Sierras take the form of a narrower chain of volcanic origin in the Cascades and a geological fault uplift in the Sierras. The northern portion of the Cascades is relatively cool and moist on the western side and relatively dry on the eastern side. The Sierras experience heavy winter snowfall but long, dry summers. Colfax, California, in the Sierra foothills northwest of Sacramento, has annual precipitation of 45.3 inches/1151 mm and, especially relevant to fire hazard, dry summers with little precipitation from June through September (Weatherbase, 2022c).

The third mountainous area is the Pacific Coast Ranges, extending from the Olympic Peninsula of Washington in the north through Oregon and south to the Transverse Ranges north of Los Angeles. In parts of Washington, northern Oregon, and central California, coastal geography consists of mountains of relatively low elevation, but in southern Oregon and the northern part of California the coastal mountains merge into the Klamath Mountains, which are rugged and extensive, with large wilderness areas. In addition, portions of the Coast Ranges in the Olympic Peninsula of Washington and in the Transverse Ranges of southern California have considerable elevations and rugged topography. Northerly portions of the Coast Ranges and those in close proximity to the ocean are moist and cool, and southern parts are drier, especially during the summer.

The precipitation regime in large areas of the westernmost part of the West is important to wildfire hazard. As noted above with the Sierra foothills town of Colfax, during the summer there is little rainfall, with the exception of occasional thunderstorms in the mountains. By midsummer, grasslands, oak woodlands, and forests are extremely dry and highly flammable. Trees in large areas of forest lands are dying because high temperatures and inadequate rainfall weaken their resistance to invasive insects (this is occurring in several parts of the West). Significant rain may not arrive until November or December, and because of drought conditions the potential for serious wildfire is becoming a year-round phenomenon.

Policy Options and Examples of Large-Scale Wildfires

Many wildfire events could be useful in an examination of the application and effectiveness of disaster preparations. In this section, three wildfires are profiled to illustrate the effects of policy options related to wildfire risk. Specific application of these options varies depending on the geographic characteristics of a particular location, governmental jurisdiction (federal, state, and local), and in some cases on debates about effectiveness among practitioners and researchers.

Camp Fire: Insufficient Preparation

Disturbing scenes of burning forests, hillsides, and homes are an expected part of media coverage of disasters in the western USA. The Camp Fire, though, was different in kind, in its speed, deadliness, and the terror it caused. It is an extreme example of outcomes when dangerous weather conditions meet insufficient community preparation for wildfire.

The fire began in the early morning of November 8, 2018, with a malfunction in an electric utility's power line, 7 miles upslope from the rural community of Paradise, population 27,000, in the forested foothills of the Sierra Nevada mountains. Weather conditions were considered "red flag" for fire, "consisting of strong winds, low humidity, and warm temperatures" (California Department of Forestry and Fire Protection, 2019). Less than two hours later, portions of Paradise were being evacuated as the fire approached, and it was not long before evacuation became mandatory for the entire area.

Paradise had been threatened by several fires in past decades. Because it is a relatively small town that grew in a rural area with little planning, residential access streets are narrow, winding, and often dead end. Not only this adds to the secluded, wooded charm of the place, but it also contributes to the hazard to life during a fire emergency. Roads leading out of the town are adequate for ordinary traffic or an evacuation with sufficient time, but not for a rapid evacuation. The town had taken some preparatory actions in advance of the fire, such as designating evacuation routes which would become one-way outgoing roads in the event of an emergency. However, not much had been done to create vegetation-free defensible space around buildings, and the fire spread rapidly, as embers fell from the approaching fire and burning buildings ignited those nearby.

Residents had little warning or time to evacuate, so traffic jams developed on major roads. In some cases, people died in their cars as the fire swept over them, and there were instances of people fleeing on foot (Knox, 2018). Many people died in their homes, especially the elderly and disabled, because they were unable to evacuate (Tucker et al., 2018). Firefighters knew they could not control a fire moving so quickly: "The incident commander leading the emergency response recognized the fire's speed and intensity and ordered his personnel to abandon all firefighting efforts just 45 minutes after the fire arrived. 'Save lives, keep evacuation moving,' the incident commander said over the radio" (National Institute of Standards and Technology, 2021). The final death toll from the fire was 85 people, and most of the town was gone. By the time it was fully contained, the fire had destroyed more than 18,000 structures.

The history of wildfire in the region included fires in 2008 that had burned a significant portion of the area covered by the Camp Fire, so this disaster was not caused primarily by insufficient attention to removing excess fuels from nearby forest lands. Instead, the fire's aggressiveness was due to the weather in combination with flammable conditions in the town. The result was shocking but not surprising, given the red flag warning and the geographic characteristic of "autumn winds that

gain heat and speed as they blow from the interior down the state's mountain ranges" (Boxall & John, 2018).

There are several important issues connected with the Camp Fire, such as utility infrastructure safety and liability, land-use planning to facilitate evacuation, and finding housing for people who are displaced by fire. The focus here is on policies that may reduce the potential hazards from wildfire incidents, such as standards for fire-resistant building construction, defensible space around structures, and low-flammability buffer zones at the wildfire-urban interface (WUI).

In California, the California Department of Forestry and Fire Protection (Cal Fire) has designated areas of high fire risk in which new buildings and major remodels must conform to building code requirements for fire resistance. The requirements of the most recent version of the code in effect during the Camp Fire were adopted in 2008. It addresses materials and construction methods for roofs, siding, vents, windows, doors, decking, gutters, and so on. In Paradise, 86% of homes were built before 1990 – long before the adoption of wildfire-related codes – and only 11.6% of these homes survived the fire. As codes changed, so did rates of survival, so the rate for homes built from 1990 to 1996 was 20.6%, 34.3% for the period 1997–2007, and 43.0% for 2008–2018 (Knapp et al., 2021).

The difference in home survival rates by time period seems impressive initially, but 43% survival for homes built using the most recent version of the code means that 56% of the newer homes burned. Also, building according to the most recent standards represented only an 8.7% greater likelihood of survival over homes built in the immediately preceding period. There were complicating factors as well that make assessing the impact of building standards difficult, such as smaller lot sizes in older areas, so that structures were closer together and fire in one building was more likely to ignite adjacent buildings (Knapp et al., 2021). Overall, according to Knapp et al. (2021: 16), "proximities to neighboring burning structures and surrounding vegetation" were especially important elements of survivability in the Camp Fire, and "to maximize survivability, homes need to be designed and maintained to minimize the chance of a direct flame contact, resist ember ignition, and survive extended radiant heat exposure."

In the period following the Camp Fire, the Conservation Biology Institute, The Nature Conservancy, and the Paradise Recreation and Parks District "partnered to explore community design elements with the intention to test the concept that a community can be protected from ignitions from wildland fires with the use of Wildfire Risk Reduction Buffers (WRRBs) between the urban area and the wildlands" (Conservation Biology Institute, 2020: 3). Much of the commentary on the Camp Fire focuses on vulnerabilities within the developed area of the town, and fire ignition in Paradise was often caused by embers blown from a distance. Nevertheless, it was assumed there might be preventive benefit from creating defensible space on the boundaries of the community. Such spaces could include parkland, orchards, or other low-risk uses, along with wildland "managed for fire risk reduction" (3).

Project consultants used scenario modeling with technical data and community input to draft maps of fire vulnerability for parcels both close to the boundaries of Paradise and some distance away. They included recreation and conservation values

in the analysis, producing a complex set of recommendations involving purchase of high-risk parcels in private ownership, coordination with the BLM and Forest Service on treating their land to reduce fire hazard, and using conservation easements to encourage hazard reduction on private land. The community reception for these recommendations was positive, though study authors “concluded that the challenge lies not in convincing people that these planning measures would help, but in finding ways to overcome the barriers to accomplishing them” (Conservation Biology Institute, 2020: 6).

The Recreation and Parks District is anticipating federal funding to hire additional implementation staff and to acquire some of the prioritized parcels. People involved in the project understand “the limitations of the buffer: It should help protect lives and property, but it can’t prevent wildfires to begin with” (Smith, 2022). According to a project manager for The Nature Conservancy, “We’re assuming that [it] would slow the fire down enough to allow more time for evacuations, and allow more time for emergency services to muster and do what they need to do” (Smith, 2022).

Thomas Fire: Comprehensive Preparation Program

On Monday December 4, 2017, strong winds in Southern California caused power lines near the town of Santa Paula, northwest of Los Angeles, to explode in an electrical arc, igniting a fire that spread rapidly. Within a few hours, the fire disabled a power station, blacking out service to 100,000 homes and businesses including much of the city of Ventura, population 110,000. By the next morning, “the fire had grown to 40,000 acres and 150 buildings in Ventura had been destroyed including Vista Del Mar hospital” (Hill, 2019). Two days after the fire started, it had expanded to the north and west; some neighboring towns were evacuated, and a hazardous air quality warning had been issued. By December 8, “3,500 firefighters, 21 helicopters, 544 engines, 46 hand crews, and 26 bulldozers had been assigned to the now 132,000-acre fire that was only 10% contained” (Hill, 2019).

This level of resource allocation was possible because of a system of preexisting agreements with fire service organizations in surrounding parts of California and in other states. Nowell and Steelman (2019: 2) described the system as follows: “In the fire service, through a web of mutual aid agreements and resource ordering systems, thousands of personnel and equipment from local, state, federal, and international jurisdictions are routinely brought together into a unified operation that functions like a single organization under the direction of an incident commander and his/her command staff.” For the Thomas Fire, the National Guard contributed helicopters and Cal Fire requested “every last plane we could find in the nation.” C-130 aircraft came from the military, and “more than 290 fire engines came from Montana, Utah, New Mexico, Idaho, Arizona, Oregon and Nevada” (Spagat & Melley, 2017). As an example, lightly populated Montana is as far from Southern California as any part of the western states, some 1200 miles (1900+ km) distant, and they sent “three strike teams with 15 engines and 55 people from 14 agencies” (Associated Press, 2017).

The fire grew westward, moving away from Ventura and along the coastal mountains toward Santa Barbara (population 88,000). By December 9, mandatory evacuations were withdrawn for Ventura, but some 530 homes had been destroyed. On December 10, mandatory evacuation was ordered for coastal communities including the unincorporated town of Montecito, population 8600, and evacuation advisories were issued for eastern Santa Barbara (Hill, 2019). Montecito adjoins Santa Barbara on the east, and it is located on a coastal plain beneath the Santa Ynez Mountains, which have elevations in excess of 4000 feet (1200+ meters). The northern city limit is a five-mile (8 km)-long wildland-urban interface contiguous with the Los Padres National Forest.

On December 16, the Thomas Fire burned along the northern border of Montecito. In contrast with other areas in which many homes were burned, and despite the intensity of the fire and the length of the exposure to wildland, only seven residences were destroyed in Montecito. The Montecito area had historically experienced damaging fire events, so for two prior decades the Montecito Fire Protection District had worked to implement comprehensive preventive measures in preparation for the next major fire. These included the following: printed maps of fire attack routes for use by other agencies; building code measures such as prohibiting the use of wood shake roofs and siding; wider residential driveways to accommodate fire equipment; defensible space around structures; reduced flammable materials along roadways to prevent entrapment during a fire; and a buffer zone with fuel reduction treatments. Two of the seven residences lost to the fire were located near a gap in the buffer, and the others had fuels that were not cleared away from the buildings (Gabbert, 2019).

By late December, the fire had turned away from populated areas, though it continued to burn in backcountry. It was declared fully contained on January 12, 2018, after burning 281,000 acres and destroying 1063 structures. It had spread over 42 miles from east to west (Hill, 2019). Unfortunately, the Montecito story did not have an entirely satisfactory ending. It was clear to officials that the burned area on steep slopes above the town presented a mudslide hazard in case of significant rainfall, so they put in place a voluntary evacuation order for an area that appeared most at risk. Some residents, though, stayed in their homes (Karimi & Almasy, 2018). Early on January 9, 2018, a rainstorm caused a mudslide carrying large boulders that flowed into a portion of Montecito, destroying more than 100 homes and killing 23 people (California Governor's Office of Emergency Services, 2021).

Bootleg Fire: Testing Forest Management Options

The Bootleg Fire occurred in south-central Oregon northeast of Klamath Falls, on a high plateau approximately 5000 feet/1500+ meters in elevation at Sycan Marsh, discussed below. In contrast to the Camp and Thomas fires, the Bootleg Fire mostly affected forested federal and private land and a private nature preserve, though a number of structures in rural areas were also destroyed. It was caused by lightning and burned more than 400,000 acres in the period July 6 to August 15, 2021.

Because much of the land had been logged or burned for several decades and densely populated communities were not involved, this event can seem unremarkable compared to other recent fires. However, the presence of a large project modeling forest management techniques makes this fire particularly relevant to ongoing discussions about how to address the buildup of fuel loads in forests.

On one side of this issue is a cartographer who mapped forest conditions in the Bootleg Fire area, finding that it burned through areas of tree thinning and prescribed burning without slowing down. Another analyst found that commercial logging and livestock grazing caused the fire to move faster than it did in a federal wilderness area where the forest was undisturbed. Forest Service staff had a different perspective, arguing “that their prescribed fire and tree-thinning work successfully reduced the intensity of the Bootleg Fire” (Neumann, 2021). For the Forest Service, the important question was not how fast the fire moved, but whether fire intensity was so severe that it spread into the crowns of trees instead of burning only along the ground, killing trees in addition to clearing away fuel accumulation.

The practice of thinning forests has been controversial. Some researchers think thinning is merely a rationale for increased logging that benefits private industry and the budgets of federal agencies (Hanson, 2021). In addition, there is some evidence “that forests with the highest levels of protection from logging tend to burn least severely” (Bradley et al., 2016: 9), a finding that contradicts common understanding about the relationship between forest density and fire. Studies of tree thinning across many sites show a variety of results in relation to wildfire, involving factors such as heating and drying in a forest when the tree cover is reduced, and the amount of surface fuel remaining after the thinning process. Prichard et al. (2021: 10) wrote that, on balance, “the capacity for thinning alone to mitigate wildfire hazard and severity is not well supported in the scientific literature.” However, research indicates that thinning can be effective in reducing fire severity when used in combination with prescribed burning, so that: “although the efficacy of thinning alone as a fuel reduction treatment is questionable and site dependent, there exists widespread agreement that combined effects of thinning plus prescribed burning consistently reduces the potential for severe wildfire across a broad range of forest types and conditions” (10).

On the eastern side of the area burned in the Bootleg Fire is a 30,000 acre Nature Conservancy preserve in an area called the Sycan Marsh. It is a broad area of grasslands and forests that the Conservancy uses as a laboratory for fire management techniques, treating blocks of forest with combinations of controlled burning and thinning (McClain, 2021). For more than 15 years, they have worked collaboratively with “forest ecologists and fire practitioners, international researchers, scientists and Indigenous peoples” (Nature Conservancy, 2020) to improve wildfire management and make forests more resilient given the pressure of climate change.

There is a research station on the preserve that houses researchers and equipment, and when staff saw the Bootleg Fire approaching with flames shooting above the burning crowns of trees, they feared the station could be lost. When the fire came closer, though, it encountered treated areas of forest and its character changed, as

flame height dropped and the fire moved around the research station without damaging it (Fountain, 2022).

Periodic prescribed burning appears to be less controversial among the practice and research communities than thinning alone for reducing the severity of wildfires. Prescribed burning has been an accepted practice in states in the Southeastern USA for decades, and 11 states have established certification programs for people who supervise burns (Sommer, 2021). The situation in the western states is somewhat different, where the climate is dry, prescribed burning is not as well accepted, and using it at scale is difficult. Roughly 120 million acres are at risk from wildfire, but federal agencies have only been able to treat 2.5 million acres annually (Chabria & Wigglesworth, 2021). In addition, burns must be repeated periodically as new vegetation grows to replace what has been burned.

In the current setting of climate change, drought, and some prescribed fires burning out of control, the public in the western USA is becoming more sensitive to the practice. A large, damaging fire in New Mexico began in April 2022 when Forest Service personnel lost control of a prescribed burn. Later in the year, the Forest Service published a report analyzing the causes of the incident, finding that officials “underestimated the amount of timber and vegetation that was available to fuel the flames, the exceptionally dry conditions and the rural villages and water supplies that would be threatened if things went awry” (Associated Press, 2022). In a surprising recent event that highlights public resistance to prescribed burning, when a fire set by the Forest Service in eastern Oregon spilled over to burn several acres on private land, the landowner called the county sheriff. The sheriff arrested the federal officer managing the burn, on a charge of reckless burning that carries a potential jail term of 1 year and a \$6250 fine (Canon, 2022).

It is not only the policy option of prescribed burning that is challenging to implement in today’s political environment. The policy of most state fire agencies is to extinguish all reported fires as soon as possible. On federal land, the situation is more complex, in part because of resource limitations and in part because of the goal of using fire to reduce fuel loads. Fires occurring in remote wilderness areas and at high elevations are often left to burn out on their own, and in other areas they may be monitored to determine the potential for hazardous expansion. Fires occurring in areas in need of periodic burning can serve forest management objectives, provided they do not grow to the point of damaging valued land or communities. This is the policy of “managed fire,” determining in each case the probabilities of damaging fire expansion.

This policy is difficult to sustain when managed fires burn out of control. Two small lightning-caused fires were left to burn on Forest Service land in California in July 2022, but the weather changed and they expanded rapidly, destroying several dozen structures. This prompted the governor of California to ask the federal government to adopt a more aggressive fire response stance (Chabria & Wigglesworth, 2021). Commenting on use of managed fire in a time of public concern about fire spread, Davis et al. (2022: 916) suggested that, “In this context, the policy allowing managed wildfire and growing scientific consensus about its value appear insufficient to support its broader use.”

Conclusion: Challenges and Opportunities in Reducing Wildfire Risk

The frequency, intensity, and damage potential of fires in the western USA are likely to increase substantially in the next several years due to climate change, forest conditions, and continued development in the wildland-urban interface. There are several options available to decision makers working to reduce the danger from wildfire, so policies can be crafted to fit location-specific characteristics and assessment of tradeoffs between cost and risk. The examples of the Camp, Thomas, and Bootleg fires suggest that single-focus approaches such as prescribed burning or strengthened building code standards are often insufficient on their own. Instead, to offer a reasonable probability of effectiveness, an adopted policy will likely include a package of options, drawn from the concepts of buffer areas, defensible space around structures, fire-resistant buildings, and techniques of forest management.

To transition to a broader perspective, Schoennagel et al. proposed an “adaptive resilience” approach with the following four elements: “(i) recognizing that fuels reduction cannot alter regional wildfire trends; (ii) targeting fuels reduction to increase adaptation by some ecosystems and residential communities to more frequent fire; (iii) actively managing more wild and prescribed fires with a range of severities; and (iv) incentivizing and planning residential development to withstand inevitable wildfire” (2017: 4582). A parallel to this multifaceted approach is found in research from Calkin et al. (2014), who addressed the problem from the perspective of risk analysis. They also moved beyond sole focus on wildland conditions to include fire-resistant buildings, defensible space, and emergency response, stating that, “if the goal is to have fire-adapted communities, successful and efficient wildfire response, and resilient landscapes, an integrated risk-sharing approach is required” (751).

These are promising perspectives on the future of wildfire risk reduction, but there are also constraints on what might be accomplished. Fragmentation can make it time-consuming to formulate and implement a wildfire policy, as participants may include property owners, the general public, and local, state, and federal agencies. The project for creating buffers around the town of Paradise is an example, requiring sustained effort at coordination. Institutional complexity is a potential constraint, as large agencies respond to input from multiple internal and external sources. One of those inputs is public perceptions of risk. Property owners may focus on their individual circumstances without taking into account community-wide and longer-term goals; the local arrest of a Forest Service officer in Oregon is an example. Technical issues of implementation are important as well. Predicting weather conditions and the risks of fire spread could become more difficult with climate change and continued development adjacent to wildlands, thus complicating decision-making about prescribed and managed fires. Finally, resource availability and the cost of options included in a particular policy are potential constraints, as they are in many policy settings.

In sum, this is a long-horizon process operating at different levels, subject to changes in the physical and social environments that are difficult to foresee.

Schoennagel et al. (2017: 4588) captured the complexity of this setting well, suggesting it means that “embracing rather than resisting ecological change will require a significant paradigm shift by individuals, communities, and institutions and will challenge our conservation philosophies.”

Abstract

In the last decade, the Artificial Intelligence (AI) revolution has led to significant advances in science and technology. AI algorithms have become proficient in recognizing faces, understanding speech, translating between hundreds of languages, retrieving relevant information in response to ambiguous queries on the Web, and beating humans at challenging games such as chess and Go. These advancements led to cutting-edge technologies such as AI-driven smart assistants, self-driving cars, housecleaning robots, and delivery drones. The disaster response and management domain has also benefited from these advancements. This chapter covers a wide range of tasks where AI's potential is evident, including remote sensing for flood mapping and monitoring, social media information for assisting relief operations, event summarization, and geolocalization of disaster impacts. The chapter also highlights the role of mobile devices in crisis communication and disaster management in general and discusses the role of unmanned vehicles for searching and mapping tasks during disasters.

Introduction

Artificial Intelligence (AI) provides new ways of approaching problems and serves as a tool to explore and address hard, unanswered questions. Technological advancements backed by AI-driven innovations are transforming many application areas, including drug discovery (Fleming, 2018; Stokes et al., 2020), disease prediction (McKinney et al., 2020; Mohan et al., 2019), medical image analysis (Litjens et al., 2017; Shen et al., 2017), autonomous driving (Levinson et al., 2011; Yurtsever et al., 2020), spoken language understanding (Levinson et al., 2011; Serdyuk et al., 2018), and sustainable development (Vinuesa et al., 2020; Weber et al., 2021). Similarly, AI-based technologies are playing an increasingly important role in disaster response and management and have the potential to help humanitarian organizations with enhanced early warning, situational awareness, and impact assessment systems (Sun et al., 2020). This section discusses the role and opportunities of AI and unconventional data sources, including satellites and social media platforms, for disaster risk reduction. Specifically, the section contains 12 chapters that cover different aspects of using emerging technologies and AI to build innovative applications for DRR.

Remotely sensed data, e.g., by satellites, can provide valuable information in all stages of disaster management cycle, i.e., reduction, readiness, response, and recovery (Boccardo & Giulio Tonolo, 2015; Joyce et al., 2009; Van Westen, 2000). That is, remote sensing analysis can (i) help to determine which areas are more vulnerable to hazards, (ii) enable monitoring of an ongoing disaster and organizing emergency operations, (iii) provide a quantitative base for relief operations in damage assessment and disaster aftermath, and (iv) assist in the organization of the damage-related information and the postdisaster census information as well as the evaluation of sites for reconstruction. ► [Chapter 39, “Remote Sensing Tools for Crisis Assessment in DRR,”](#) illustrates how humanitarian organizations such as United Nations Development Program (UNDP) and United Nations Satellite Centre (UNOSAT) employ such AI-enabled technologies in their operations including examples from the Bata explosion and the Timur Leste flood. Then, ► [Chap. 45, “Remote Sensing for Flood Mapping and Monitoring,”](#) takes a deep dive into a particular disaster type, i.e., floods, since they are the most frequent type of natural disaster and affect more people than any other natural disaster type. The chapter presents a comprehensive overview of remote sensing applications for flood management including flood detection, flood delineation of affected areas, and damage assessment and investigates existing products and services that currently provide useful insights about past or ongoing flood disasters to emergency response operations.

Social media has permeated in and become an integral part of everyday life, including before, during, and after emergencies (Reuter & Kaufhold, 2018; Simon et al., 2015). Hence, social media data presents unprecedented opportunities for DRR that also come with various computational as well as system design challenges (Imran et al., 2020). ► [Chapter 40, “Big Data and Multi-platform Social Media Services in Disaster Management,”](#) presents a multiplatform service for gathering big social data across different social media channels and analyzing the credibility and relevance of collected data through AI models. The chapter also discusses core challenges and potentials of such services, focusing on (i) the multiplatform

gathering and management of data, (ii) the mitigation of information overload by relevance assessment and message grouping, (iii) the assessment of credibility and information quality, and (iv) user-centered tailorability and adjustable data operations. Ideally, these systems must follow a systematic design to employ AI-assisted data processing that is (i) modular to create processing pipelines for different data types, including text, videos, images, and numeric sensor data; (ii) extensible to newer analytical capabilities; (iii) interactive for greater human control; and (iv) adaptable to dynamic human needs; all of which is achievable with the help of a human-centered approach. To this end, ► Chap. 35, “Citizen-Helper System for Human-Centered AI Use in Disaster Management,” introduces and illustrates different applications of human-centered AI system design in managing social media data to support use cases in different disaster management phases using an example of one such system called Citizen-Helper. The lessons learned from implementing Citizen-Helper facilitate an understanding of challenges and practitioner expectations for future research and development of human-centered AI applications within different phases of disaster management.

Humanitarian organizations have started relying more and more on social media data to initiate and assist rescue operations (Meier, 2015; Stephenson, 2005). However, there is no one-size-fits-all solution that can help all humanitarian organizations as their information needs vary greatly, from a general summary to specific needs (e.g., infrastructure damage, missing people, and injured or dead individuals). These high-level information categories may also contain several small-scale subevents that capture information from diverse dimensions. ► Chapter 42, “Role of Crisis Information Summarization Through Microblogs in Disaster Management,” addresses this challenge and covers details about subevent detection and summarization strategies such as identifying subevents as event-action pairs from social media posts (e.g., tweets) and jointly optimizing them into coherent event summaries in near real time. Social media data can prove useful for postdisaster relief operations, as well, where management of the distribution of emergency resources requires the knowledge of (i) resource-needs, i.e., what resources are required, and (ii) resource-availabilities, i.e., what resources are available in the disaster-affected region or potentially elsewhere. Since it is challenging to collect such firsthand information on the ground in real time, ► Chap. 41, “Role of Microblogs in Relief Operations During Disasters,” shows how reliable and automated computational methods can be developed for identifying and matching resource-needs and resource-availabilities from social media data during postdisaster situations. On the other hand, one of the weaknesses of social media data is the oftentimes unavailability of accurate geolocation information, which typically plays an essential role in disaster management as crisis maps allow affected people to share updates on their statuses and needs, which enable a rapid response, while they also allow response authorities to manage their response activities (e.g., routing rescue teams), and reduce the impact of disasters by planning future activities (e.g., evacuation). ► Chapter 44, “Role of Geolocation Prediction in Disaster Management,” focuses on this critical problem and links humanitarian organizations’ requirements with existing computational methods for geolocation inference and introduces the computational tasks that fulfill humanitarian organizations’ unmet needs.

Not only the textual content but also the visual content (i.e., images and videos) on social media has proved very effective in analyzing the scale of damage to infrastructures (e.g., roads, bridges, and buildings) as well as in understanding people's perceptions, emotions, sentiments, and responses to disasters. Assessing such aspects of disaster events requires effective and efficient computer vision methods to process the large amount of social media visual content. On this note, ► Chap. 38, “Role of Social Media Imagery in Disaster Informatics,” reviews state-of-the-art techniques and publicly available resources (datasets and models) and shows their utility in processing social media image streams during disasters for a diverse set of applications. Putting a different spin on the problem, ► Chap. 43, “Disaster Rescue Communication Using Mobile Devices, Social Media, and Artificial Intelligence,” focuses on how mobile devices, social media, and the use of AI in the form of AI-infused information technologies can meet the communication and information needs of crisis managers. In examining research on mobile phones, the chapter reveals the pivotal role they play in helping people participate in more conversations that can increase their chances for receiving help and for providing early alerts.

On the mechanical systems side, robots such as unmanned aerial vehicles (UAVs) and unmanned ground vehicles (UGVs), among others, can assist humanitarian organizations by searching, mapping, delivering supplies and medical treatment, and evacuating casualties (Murphy, 2014). To that end, ► Chap. 37, “Ultralight Platforms to Coordinate First Responders and Communications,” reviews the aerial technology available today, introduces a new solar-powered, propeller-driven, lighter-than-air architecture as an emerging technology, illustrates its potential use cases during disasters, and discusses existing regulations and support for emergency systems.

Taking a step further, ► Chap. 36, “Resilient Heritage Using Aerial and Ground-Based Multi-sensor Imagery,” proposes a methodology that combines geospatial information from satellites, drones, smartphones, and historical maps to increase cultural heritage resilience to various disasters such as earthquakes, wildfires, and floods. The chapter illustrates through real-world case studies that the proposed methodology can mitigate damage incurred by disasters, thanks to faster and more accurate data acquisition, and help preserve the identity and unique value of cultural heritage.

Conclusion

In summary, this section covers a wide range of areas where AI’s potential for DRR is evident, including remote sensing for damage assessment and monitoring, social media information for assisting relief operations, event summarization, and geolocalization of disaster impacts. In addition, it highlights the role of mobile devices in crisis communication and disaster management in general and discusses the role of unmanned vehicles for searching and mapping tasks during disasters. It is important to note that such potential benefits of AI for DRR must be contextualized

with the other sections of the handbook to warrant a transdisciplinary approach to disaster management.

Abstract

Traditional approaches to aid disaster management practitioners during response and recovery require extensive effort to timely collect, process, and analyze semi-structured data for extracting relevant information from various sources. Similarly, training instructors rely heavily on manual tasks to collect and analyze trainee performance data during the mitigation and preparedness phases. Efforts to collect and analyze data can be partly attributed to the minimal integration of advanced information technologies in current disaster management practices. The

growing adoption of sources like social media (SM) and Internet of Things (IoT) networks provides a unique opportunity to collect additional data to aid all disaster management phases. Artificial intelligence (AI) technologies present an unprecedented era to design information systems that can process data from SM and IoT sources at scale in real time to enhance disaster response processes and training performance analyses. They require a systematic design to employ AI-assisted data processing that has the modularity to create processing pipelines for different modalities, including text, videos, images, and numeric sensor data, extensibility to newer analytical capabilities, interactivity for greater human control, and adaptability to dynamic human needs. It is achievable with the help of a human-centered approach. This chapter introduces and illustrates different applications of human-centered AI system design in managing SM and IoT data to support use cases in different disaster management phases using an example of one such system called Citizen-Helper. The lessons from implementing Citizen-Helper use cases will facilitate an understanding of challenges and practitioner expectations for future research and development of human-centered AI applications within different phases of disaster management.

Introduction

Disaster Management and Information Needs

Disaster management is essential to the safety and security of people and property before, during, and after disasters. Disaster management is primarily divided into four distinct phases, as identified in Fig. 1 (FEMA, 2013). Each phase plays an integral role in preparing for, responding to, and recovering from disasters.

The mitigation phase focuses on preventing or minimizing the impact of disasters on people and property. For example, reinforcing structures such as levees or fencing prone to damage in disasters is a form of mitigation, or conducting training for disaster responders is another form of mitigation. The preparedness phase focuses on taking readiness actions for responding to disasters. For example, disaster management agencies that conduct exercises and drills and community members creating disaster supply kits are different forms of preparedness. The response phase focuses on protecting life and property during and immediately following a disaster. For example, evacuating, assessing damage, and conducting search and rescue missions are forms of response. The recovery phase focuses on rebuilding following a disaster. For example, disaster victims seeking financial assistance and restoring power and communications are forms of recovery. Throughout all phases of disaster management, a common theme is the need to attain information. These information

Fig. 1 Disaster management phases

can range from extracting serviceable requests for help during response phases to collecting updates on recovery of roads/houses or to acquiring knowledge of the trainee responders' location during simulated training exercises. Thus, the field of disaster management could benefit from advancing technological capabilities to help prevent, prepare, respond, and recover from a disaster.

Disaster management agencies mitigate the risks and consequences of disasters by processing information from multiple sources in their decision-making. Disaster management agencies need timely access to relevant information to serve their community. Following disasters, these agencies also benefit from corrective action plans. These plans are developed to prevent the recurrence of challenges experienced during a past disaster.

Computer-Assisted Information Processing for Disaster Management

Traditionally, disaster management practitioners in agencies comprehensively examine the response to disaster events to learn what went right and what requires improvement for future disaster response. Thus, the practitioners, along with researchers, had to perform critical after-action analysis and extensive research through rigorous surveys, interviews, after-action reports, and ethnographic studies (DHS, 2013; Kapucu, 2008; Powell et al., 2012; Texas Department of State Health Services, 2018). Moreover, disaster management practitioners are involved in

analyzing data during disasters. However, much manual labor and time are required, and these methods are not scalable and are tedious for all disaster scenarios. Additionally, it is challenging for disaster management practitioners to analyze data during disasters, while concurrently making operational adjustments resulting from the disaster's impact. Further, traditional ways of finding and analyzing relevant information often rely on a limited number of experts who are trained specifically for that task (Plotnick & Hiltz, 2016; Reuter et al., 2016).

However, the development and deployment of systems for computer-assisted information processing have helped mitigate many limitations of traditional approaches (Imran et al., 2020; Senarath et al., 2021). These information processing systems have helped disaster management agencies organize and manage data collections from different events, while providing methods to process and manage them at scale (Careem et al., 2006).

Modern information systems can provide disaster management practitioners with the power of processing and ingesting relevant information from nontraditional data sources such as crowdsourced and social media data. Moreover, these collections of nontraditional data could be accessed and shared easily among different agencies or response teams to analyze data for enhanced, unified situational awareness (shared understanding of the environment (Endsley, 1988)). Thus, the actions to collect and process relevant information from various sources for decision support may now be completed in less time due to reduced manual labor.

However, there are some limitations to using computer-assisted information processing. The techniques to process nontraditional data may not be efficient due to the challenges of unstructured data, e.g., interpreting the relevance of noisy, ungrammatical, and user-generated content of social media (Purohit et al., 2018b). The features of an information system should be readily available to customize for adjustments such as updating the AI models to maintain their performance for extracting relevant information. This is required due to the dynamics of disaster events and the changing information needs of decision-makers during the response.

With the recent advancements in AI, researchers have developed techniques to efficiently process raw data (e.g., social media data, sensor data, etc.) to aid data analytics systems for decision support at disaster management agencies (Imran et al., 2015; Purohit & Peterson, 2020). Some examples of current AI-based data analytics systems for disaster management are Citizen-Helper (<https://citizenhelper.orc.gmu.edu/>) (Pandey & Purohit, 2018), AIDR (<http://aidr.qcri.org/>) (Imran et al., 2014), Dataminr (<https://www.dataminr.com/>), etc. (given the scope of this chapter is to focus on explaining human-centered AI design and its use cases, we recommend readers to check a detailed survey on various types of software systems for disaster management in Hiltz et al., 2020). However, most AI-based data analytics systems are still in the early stages of success for deployment at disaster management agencies at large and require various improvements based on the experience of disaster management practitioners from different places and working from local to global levels. This challenge demands consistent collaboration between technical teams and disaster management practitioners, as detailed in the next section.

Need for Human-AI Collaboration for Information Processing

Modern AI systems are designed to deliver a scalable processing and analysis of data to lead to accurate predictions for various tasks. However, they fail when the processing and analysis of complex data such as unstructured multimodal data require a high level of cognition and understanding of context changes that humans are generally capable of (Monarch, 2021).

This section describes the challenges of employing AI technologies to augment information processing without human supervision, which motivates the need to develop a collaborative approach of human-AI collaboration, i.e., a human-centered AI design (Shneiderman, 2020b) for information systems to support disaster management practitioners (see illustration of such a system in Fig. 2). We also cover the limitations of those modern AI technologies and the significance of human involvement in those systems.

Limitations of AI Technologies

The primary concerns with employing information systems in practice with fully automated solutions based on AI technologies include reliability and trustworthiness of computation (Shneiderman, 2016, 2020b). Recent research has shown the possibility of severe consequences when deploying AI technologies in high-risk environments without human involvement (Sambasivan et al., 2021).

AI technologies without human intervention can lead to poor performance for information processing due to the changing context and a lack of supervision (Monarch, 2021), especially during disasters that require time-sensitive decision-making. Moreover, building a one-size-fits-all AI system can be challenging for every situation in disaster management. Hence, the performance of AI systems must be monitored throughout its implementation for errors and biases to reduce the chances of ineffective decision support and, thus, prevent the risk of misleading

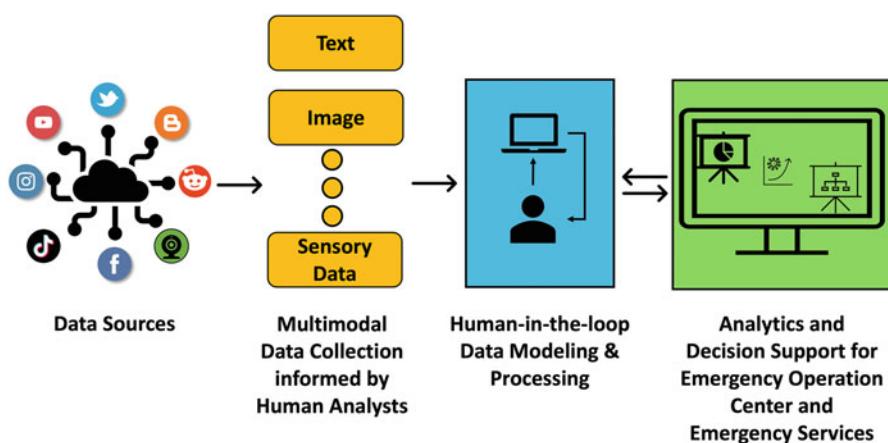

Fig. 2 Overview of a human-centered information processing system

disaster management practitioners. AI systems can carry inherent biases that should be carefully considered before implementation (Danks & London, 2017; Shneiderman, 2016).

Furthermore, real-world data is typically unstructured and noisy, making it hard for AI systems to understand the meaning intended in the content correctly (Bender & Koller, 2020; Purohit et al., 2018b). Hence, there is a need for external intervention in AI systems to make them more robust.

Recent years have shown that the general public and volunteers can serve as a valuable resource to disaster management agencies to help improve AI systems by, for example, providing data annotations or labels to develop and adapt machine learning models during the times of disaster events (Meier, 2015; Pandey & Purohit, 2018). These resources can help address the limitations of AI systems, while accounting for two existing gaps known in disaster management – limited human resources and their minimal time availability. However, a systematic collaboration approach between humans and AI systems is required to leverage such an additional resource for disaster management agencies. Such collaboration enables a feedback mechanism for the user to alter the behavior of the AI system processes at any stage. We further describe the need for involving practitioners in the system design to address the limitations of AI technologies next.

Significance of Practitioner Involvement in System Design Beyond Evaluation

As AI-based data analytics systems are limited by their ability to understand unstructured data accurately and make predictions using real-world data, humans can help in this process to make them better. While the involvement of practitioners is essential during the evaluation of an AI system's performance to cater to disaster management needs, it is also critical during the design and implementation of such systems (Shneiderman, 2016). The continual collaboration with practitioner end users can reduce the time for system improvements to adapt to evolving requirements of disaster management agencies.

Without the involvement of practitioners in the AI system design, there could be a loss in the performance or accuracy of a deployed AI model over time due to the changes in disaster situations, such as owing to data drift (Pandey et al., 2022). The developers and disaster management practitioners should carefully monitor the AI system's performance to prevent negative consequences resulting from inaccurate, partial, or stale labeled data over time.

Engaging with disaster management practitioners can provide invaluable feedback, such as characterizing their information needs during different disaster types to help define the relevant class labels to train AI models. This approach helps developers identify the correct requirements to build and implement an AI-based data analytics system. Moreover, human help is needed in annotating the data to build an effective AI system. While such systems can be developed without labeled data using unsupervised learning methods, it can be hard to evaluate them. The performance of those unsupervised learning methods could be lower than supervised

learning methods, which have the advantage of learning patterns from ground-truth labeled data.

Using AI systems for continuous streams of data poses additional challenges. There could be a potential change in the distribution of data over time, which requires dynamic updates of the decision boundaries of the AI models. Hence, to tackle this situation, human involvement needs to capture these changing decision boundaries in a feedback loop with the AI systems to manage data drifts (Monarch, 2021; Pandey et al., 2022). Moreover, the context of information needs will change over time as disaster management practitioners transition from disaster response to recovery. Hence, there is a need for constant monitoring of AI systems through a collaborative setup of developers and disaster management practitioners to update the system requirements and adapt the AI models for the evolving information needs.

The above scenarios help understand the significance of human involvement in different phases of AI system design and deployment. In this chapter, we illustrate the approach of human-centered AI design (Shneiderman, 2020b) using a system called Citizen-Helper that aims to address the above requirements of human involvement in different ways. The comparison of the performance of such systems and various AI systems for disaster management is beyond the scope of this chapter, given the focus is to explain the design elements and use cases of human-centered AI design. Citizen-Helper (Karuna et al., 2017; Pandey & Purohit, 2018) is a human-centered AI system for real-time data analytics over social media, web, and IoT data streams. Its design aims to incorporate aspects of the human-centered AI framework (Shneiderman, 2016, 2020b) to improve and provide modularity, extensibility, interactivity, and adaptability for analytics over time and across events to aid disaster management agencies. This chapter describes more aspects and characteristics that inspired the design of Citizen-Helper and informs the future design of such human-centered AI systems next.

Human-Centered AI System Design: Illustration of Citizen-Helper

Traditionally, the levels of autonomy of AI systems have primarily focused on one dimension, which emphasizes that autonomy decreases with increasing human control and vice versa. However, the human-centered AI system design suggests a two-dimensional view of human control and machine automation (Shneiderman, 2020b) for AI systems. The human-centered AI approach envisions computing systems that amplify human abilities, empower them, and ensure human control such that both humans and machines benefit from each other's performance (Shneiderman, 2020a). The human-centered AI system design can help minimize the drawbacks of the traditional method of AI system development by empowering the end users and developers with greater agency and control over the AI components of the system. This section will provide an overview of how such a system is designed and what design considerations should be adhered to when developing and deploying a reliable system for disaster management by focusing on the Citizen-Helper system as an example.

Citizen-Helper is composed of several connected components that can be integrated to provide the most suitable analysis of situations as desired by the practitioners of disaster management. The specific analysis output depends on the functionality needed by disaster management practitioners, which depends on the type of disaster and its scope and severity. The design and development of Citizen-Helper system emphasize some of the core concepts from software engineering based on the design lessons learned from the human-centered AI framework (Shneiderman, 2016, 2020b) and the literature on information systems for crisis management (Muhren & Walle, 2010):

1. **Modularity:** Citizen-Helper is designed as a modular software system consisting of several core components and standardized interfaces for connections between those components. The components could be modified independently without affecting the overall system as per the requirement of human experts or practitioners. Thus, modularity favors more human control, one of the core dimensions of the human-centered AI framework (Shneiderman, 2020b). Moreover, modularity helps the developer rapidly deploy a system instance focused on relevant functionalities and analytics for specific data modalities, such as sentiment and intent analysis over textual data during a disaster. Similarly, for example, the module related to event detection over IoT sensor data could be improved based on feedback from the practitioners for focusing on specific events of interest without changing other system components.
2. **Extensibility and customizability:** Human-centered AI systems should be extensible and flexible in their design to support a multitude of disasters, data sources, and different types of analytics for different practitioner roles. The modular design of Citizen-Helper helps it to be extensible and customizable with an ability to easily integrate external AI models and web services for analytics provided by partners. Additionally, customizability enables one to quickly adapt the system to new scenarios or use cases efficiently, which is much needed in a system deployed for disaster management where distinct practitioners from multiple agencies are involved.
3. **Interactivity and simplicity:** These concepts are employed to provide greater human agency and control for analytics through interactive visualizations, thus, improving upon one of the core dimensions of the human-centered AI framework (Shneiderman, 2020b). Disaster management teams and other end users of the system may not be tech savvy. Therefore, the Citizen-Helper system interfaces are kept simple to provide intuitive means for communicating insights visually and facilitating interaction with the system to perform analysis as needed on disaster data without the complexity of coding or programming. In the design of Citizen-Helper, the focus was on a specific dimension of simplicity measured by the number of interactions needed to perform a certain task or based on the time it takes to perform a task.
4. **Adaptability:** A human-centered AI system needs to adapt its AI models over time to meet the challenges of data drift and dynamic information needs in new situations, thus, improving upon the second dimension of the human-centered AI

design, which is enhancing the computer automation (Shneiderman, 2020b). Citizen-Helper includes human feedback-driven active learning techniques to dynamically update the AI models for analytics with retraining using new annotation feedback. Moreover, Citizen-Helper provides annotator agreement analysis to extract relevant and correct annotations for model building and updating. Such features enable the Citizen-Helper system to address the concept drift of information over different phases of disaster management, which, in turn, can improve the validity and timeliness of information extracted through the system for disaster management agencies.

While a software should follow the good software practices, the above principles should be emphasized during the design and development of a human-centered AI system. The Citizen-Helper system is an example of such systems, and it is designed with the modules summarized in Fig. 3 that are divided into six categories – data collection, data storage, data annotation, AI model training, analytics services, and interactive visualization. Each of these module categories is discussed in detail in the following subsections.

Data Collection

The first process in data collection is the selection of appropriate data sources. A data source is defined as the resources to find the data according to specific problem requirements. For example, it can be a social media site like Twitter (<https://twitter.com/>), Facebook (<https://www.facebook.com/>), or Reddit (<https://www.reddit.com/>).

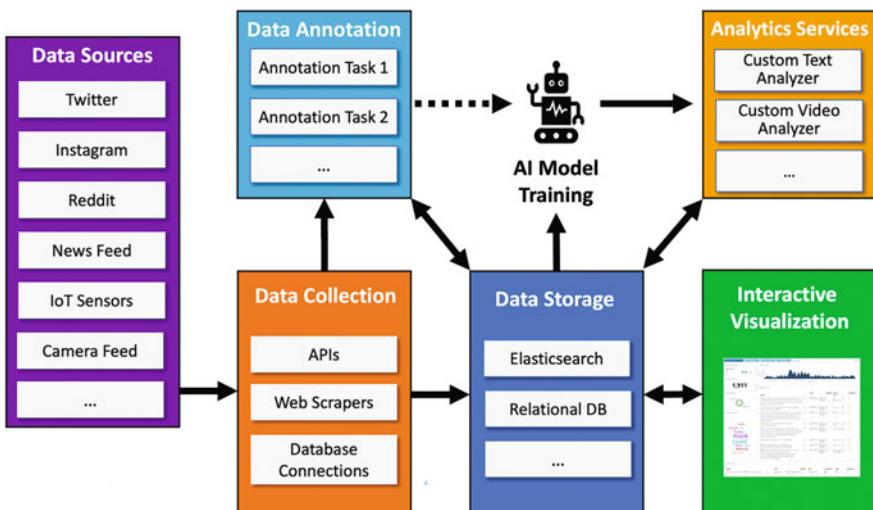

Fig. 3 Technical components of Citizen-Helper system

The source may contain data of a single modality such as text or multiple modalities (multimodal). The source may also provide data in different formats, and the process needed to collect the information may differ. One must consider the above factors when developing the data collection approach. Application programming interfaces (APIs), databases, knowledge bases, and direct sensor feed or streams are some mechanisms to collect the data from a source. It is important to note that the data collection approach should involve both developers and disaster management professionals since it requires the selection of data sources and filtering strategies appropriate for the operations of the concerned disaster management agency.

Data Storage

The collected datasets can be stored in a local server or the cloud, as per the disaster management team's requirements. Citizen-Helper uses file-based storage, relational database, and Elasticsearch (<https://www.elastic.co/>) to store data at different processing stages. It is helpful to note the use of different storage mechanisms, and it is to be carefully used when designing a human-centered AI system. For example, Elasticsearch is a full-text search engine based on Apache Lucene and NoSQL database for fast retrieving unstructured text data. Elasticsearch also has support for visualization with tools such as Kibana (<https://www.elastic.co/kibana/>) already, without any need for additional coding for rapid development and deployment of visual analytics dashboards during disasters. In contrast, using relational databases for storing the feedback provided by the end users is appropriate as it complies with ACID (atomicity, consistency, isolation, and durability) (Atzeni et al., 2013) properties of databases. Moreover, it could be beneficial to log all operations on databases to analyze them to improve the system functionality and use them for research purposes in the future.

Another aspect of data storage is the redundancy and backups to improve the availability of the systems at all times of critical stages. These options are often available through the cloud provider of the data storage services. Further, data security is another concern that needs to be carefully addressed to protect the integrity and privacy of user data, including the sources of data and system users. Data transmission must be performed using secure methods (e.g., using the Secure Sockets Layer (SSL) method), and data should be stored in access-controlled databases and servers. Only authorized users must have the required access to both the database and interactive visualization to prevent data breaches and unsolicited manipulations of the system behavior, especially for active learning techniques that update AI models.

Data Annotation

The inclusion of humans in the system design is significant in various stages of the human-centered AI approach. Citizen-Helper system design includes a module to

collect annotated data from expert and nonexpert human users to train and update AI models using supervised and semi-supervised learning methods. Before participating in data annotation tasks for creating the dataset, both practitioners and volunteers must be trained to effectively perform the desired annotation task (Senarath et al., 2021). It will reduce the risk of erroneous annotations, which could lead to low performance for the resulting AI models, leading to poor quality of analytical outputs and insights for practitioners at disaster management agencies. Training human users for data annotation tasks requires two critical components: a schema for class labels and a training guide for annotation.

Schema and annotation. The developers, with the help of disaster management experts and existing literature, must define the schema for labels of relevant information classes according to the expected analytical outcome and functionality of the system. However, developing the schema may not be one time and may require refinement due to the change in information needs of practitioners driven by the dynamics of disaster events and the analytical requirements of the disaster management agencies.

The trained human workforce is provided with one of the web interfaces of Citizen-Helper designed for data annotation tasks, which allows annotating single or multiple data items according to the defined schema, for instance, annotating a social media post by assigning a class label from a given set of labels – requesting help, offering help, and neither (Purohit et al., 2013). Interface design should be simple and easy for the users to annotate. Another important aspect is to track the annotation agreement among users, which is a well-known measurement approach for paid crowdsourcing platforms. The team leaders can leverage such performance metric analyses for future annotation task assignments or improve the human training curriculum. At the same time, the system developers can gain insights into the complexity of interpreting specific class labels and discuss the improvements for a schema with practitioners.

Human training. Presentations and tutorials have proven to be helpful for data annotation task training; furthermore, providing detailed and precise documentation is helpful to the annotators (Purohit et al., 2013). Additionally, incorporating a diverse set of annotation examples in the training curriculum can improve annotators' understanding of the task. A disaster management practitioner should conduct the training to ensure annotators understand the annotation schema's purpose, intent, and value to disaster management processes.

However, there can be significant challenges to efficient work output from humans. Other factors should be considered apart from human training for credible human annotation: fair pay if not volunteering, standardized tasks, and transparency. Depending on the type of annotators, these factors are adjusted for enhancing annotation results. However, there can be numerous factors accounting for the credibility of human training even after the initial training. For example, excessive annotation tasks conducted by an individual can affect the overall annotation quality for the data annotation. Moreover, the annotator's comprehension of the training guidelines and annotation task description also affects the quality of annotation. Large quantities of complex class label annotations might cause annotators to forget

the less frequent classes and provide erroneous annotations (Pandey et al., 2022). Quality assurance should be conducted by reviewing annotation agreements among annotators. Also, Citizen-Helper reduces the risk of erroneous annotations by including a relabeling feature on the visual analytics interface performed by a disaster management practitioner. This step is conducted before annotated data is passed to revise an AI model for predictive analytics, thus, avoiding poor quality of the outputs from the resulting system.

AI Model Training and Analytics Services

The Citizen-Helper system facilitates the customization of AI model specifications, from the type of algorithm used to build the model to the specific hyperparameters of the models. An intuitive programmable interface is provided to a developer to provide necessary AI model specifications to maximize the system's adaptability. Once the model specification is decided for a use case of the system, the following two essential components are utilized:

Supervised and unsupervised learning algorithms. Using the annotated and unlabeled dataset and the desired model specification for a machine learning task, the Citizen-Helper system activates the component for algorithmic modeling. The system trains a supervised/semi-supervised learning model when an annotated/labeled dataset is available; else, it relies on an unsupervised learning model. For instance, given the annotated social media posts with labels for the serviceable request for help (Purohit et al., 2018b) during a disaster, the system trains a classification model to detect such posts automatically. Similarly, given a time series of IoT sensor observations, the system trains an anomaly detection model to discover unexpected events.

Active learning paradigm. It is a human-in-the-loop machine learning setting (Monarch, 2021), which enables the querying of human feedback when an AI model is uncertain and updating the model with additional labeled data to make the model perform better. For instance, at the beginning of any disaster event, Citizen-Helper uses a classification model to filter out relevant social media posts (such as posts related to requests for or offers to help), trained on annotated posts from either prior similar event or a small subset of posts from current event labeled by an expert. However, the outputs of these predictive models sometimes include irrelevant posts or filter out relevant ones. Hence, it is hard to become utterly reliant on a fixed machine learning model only in such situations. Therefore, Citizen-Helper uses an active learning component that helps to improve this model over time (Pandey & Purohit, 2018). Through Citizen-Helper, a disaster management agency can collaborate with volunteer groups, where a volunteer can observe incorrectly classified posts and provide correct feedback for class labels. The feedback is stored to retrain the machine learning model dynamically to predict the erroneous labels correctly. Thus, the machine learning model becomes ever-evolving and can also handle data

drift (when the label concept definition changes over time) (Pandey et al., 2022), in order to maintain effective support for analytics to aid disaster management practitioners.

Interactive Visualization

Data visualization allows graphical representation of the data to provide an easier understanding to the disaster management practitioner. Easier access to the data and insights through visualization are critical for the end users who interact with the Citizen-Helper system. Thus, Citizen-Helper makes sure to reduce the cognitive load from the data presented to its user on the visual interface. Moreover, the tighter integration of the Elasticsearch database with the Kibana visualization interface helps the end users filter the data as required to provide a smooth and interactive user experience for Citizen-Helper. The following are some of the implemented visualization types that are useful in disaster management when analyzing online social data streams:

Temporal trends. Temporal trend is used to study the changes in different disaster-related variables over time. For example, the rate of social media posts about people who need help during disasters can aid in the management of disaster response resources.

Geographical activity. Geographical activity is a crucial visualization for localizing the effects of a disaster and aiding disaster management resource allocation efforts. Geotagging metadata with sensor observations, video feeds, and social media posts can be used to visualize geographical activity.

Content analysis. Content class labels such as topic, intentional behavior, or sentiment, as well as entity annotation, help understand the meaning of the content well. They help distinguish the patterns for relevant content from irrelevant content. For example, annotating and summarizing different entities of resource types related to disaster response in social media posts could help practitioners efficiently gain situational awareness of the demand for the resources and respond accordingly.

Interactive data tables. Data tables help study individual data records and their narratives in a simple, conventional format of tables for data analysis that practitioners are used to. For example, social media posts are presented in a table with multiple columns containing the body of the post and other metadata, including content class labels such as sentiment, intent, risk behavior, and relevancy. Moreover, the data table can facilitate a practitioner to provide feedback to the system for continuous improvement on the predicted class labels.

User demographics. Demographic features are inferred from user metadata of source data (e.g., author of a Twitter post), when available, to understand how people of different demographic backgrounds are voicing concerns and being affected during a disaster. This, in turn, aids in future actions for equitable disaster management and resource assistance.

Use Cases

Disaster Response and Mitigation Using Social Media Data Analytics

The significance of information systems that take advantage of social media data is well-known in the context of disaster management, as evident from the vast research literature generated in the last decade (Castillo, 2016; Imran et al., 2015; Purohit & Peterson, 2020). This section summarizes how such a system using the human-centered AI design approach can take advantage of social media data for disaster response and mitigation using a couple of applications of Citizen-Helper.

While it is possible to prepare a Citizen-Helper deployment for some disaster scenarios, it is not possible to anticipate and prepare for all disaster scenarios. The COVID-19 pandemic was one example where Citizen-Helper deployment was conducted from the ground up with extensive collaboration with human users, including disaster management practitioners and volunteer group members. Ground-up deployment was necessary due to the unavailability of pandemic-related data to train the AI models for desired analytics to support disaster management agencies. The developers and multiple disaster management practitioners had to collaborate and devise a set of requirements that would benefit disaster management and the overall community response (Peterson et al., 2021; Stephens et al., 2021). The specific problem was determined to identify societal risk and prevention behaviors related to the COVID-19 pandemic (Senarath et al., 2021).

The first step in building the AI system was defining the risk and prevention behavior schema for social media content that could inform disaster management agencies. Accordingly, keywords relating to that defined schema were identified to help initiate the data collection process. The system developers collaborated with a Certified Emergency Manager® (CEM) to gain valuable insights into disaster management that aided in the process to define and finalize the schema for relevant class labels. (The Certified Emergency Manager® designation is an internationally recognized professional certification for emergency managers offered by the International Association of Emergency Managers (<https://www.iaem.org/certification/intro>).) These class labels informed the development of a predictive model to recognize risk and prevention behaviors from social media posts.

Next, data were collected from Twitter to find insights about the social behavior of the public in a region. In particular, Twitter API was used to collect data using the keywords identified in the previous stage from March to September 2020. Then data annotation was required to train the machine learning models to recognize the presence of different classes of behavior in social media posts. The annotation task was performed in collaboration with members of eight community emergency response teams (CERTs) in the Washington DC metropolitan region. (The community emergency response team (CERT) program trains community members in basic disaster response skills, such as fire safety, light search and rescue, and disaster medical operations (<https://www.ready.gov/citizen-corps-partner-programs>)). The CEM conducted the training for the CERT volunteer members that resulted in high-quality annotations and ensured an understanding of desired goals and

objectives for disaster management from the data annotation tasks. The volunteer annotators were instructed to do the annotation task with a simple and intuitive web annotation interface provided by Citizen-Helper. Using active learning in the back end and after initial training of the predictive model, the system also showed the likely/predicted class labels for a social media post to an annotator and sought feedback on its decisions to improve the model.

The final step was to display the analytical insights on COVID-19 risk and prevention behavior-related social media content in a simple, easy-to-understand, and interactive format for disaster management practitioners. A web-based dashboard was created to ultimately facilitate situational awareness by time, geographical regions, and user demographics.

Figure 4 illustrates the visualization dashboard of the Citizen-Helper system. It illustrates tweets captured through a specific time range during 2020 through a temporal trend, where the user could select a specific slice for deeper analysis around peaks. It also shows an interactive data table with tweets and their metadata indicating the relevance of the tweets based on whether a risk behavior is expressed in the tweet. The data table provides a feature for practitioners with the expert user role to give feedback to the system for inaccurate model predictions. The geolocation analysis section of the dashboard includes a geographical heat map that shows the distribution of tweets in an interactive world map. This visual aid could help the system users intuitively understand the spatial data. Moreover, as indicated in the dashboard, the content analysis unit shows the behavior class distributions.

Additionally, the system users (practitioners at disaster management agencies) can interact with the interface using interactive controllers to filter out content by the relevance score provided by the AI models to obtain the content filtered by different degrees of relevance. This function on the interface offers practitioners greater

Fig. 4 Dashboard containing the visualizations in Citizen-Helper COVID-19 implementation

agency (a fundamental expectation for a human-centered AI approach). The system provided an ability to attain the most relevant information on risks and prevention behavior of the public in near real time without being obstructed by the large amounts of irrelevant data, thus helping the response and mitigation operations involving CERTs. The resulting system and analyses were presented at the regional and national level committees, as well as selected for presentation at the prestigious annual conference of the International Association of Emergency Managers (IAEM) in 2021 (Peterson et al., 2021).

Preparedness via Practitioner Exercises and Multimodal IoT Data Analytics

Recall from introduction that within the preparedness phase, the focus is given to preparing for different types and scales of disasters. An example of preparedness activities is community outreach events conducted by local disaster management agencies that educate people on how to prepare for potential hazards in their community. Also, during the preparedness phase, disaster management agencies conduct discussion-based and operations-based exercises. Agencies conduct the exercise(s) and identify strengths and areas for improvement based on exercise performance, leading to planning for process improvements through implementing corrective actions and ultimately validating the actions in subsequent exercises. It includes the practice of using training instructors' direct observation and radio-based audio communication to collect data on trainee behaviors and interactions (Pandey et al., 2020). These traditional methods are hard to scale, especially with several exercise participant teams. Moreover, the limited human resources in training debriefing result in the loss of information and the ability to personalize the experience of learnings for individual trainees.

However, there is a high potential for using the emerging AI technologies of computer vision and deep learning to address the challenge of training disaster management practitioners at scale. There is a high influx of valuable data streams when such training exercises are conducted, for instance, video streams through IP cameras, sensory information from wearable IoT devices, and simulated online microblog streams from social web platforms. It presents an opportunity to capture complementary and redundant information streams during simulated training exercises and enhance debriefing sessions for training instructors using insights extracted from the massive data streams using AI technologies.

Specifically, the Citizen-Helper system deployments included preparing for an active shooter training exercise (Pandey et al., 2020) and fire incident response (Bannan et al., 2020). The goal of such deployments was the scalable and real-time processing of nontraditional, multimodal data streams during training exercises of disaster management practitioners to augment trainees' learning experience during training debriefs immediately after the exercises. As stated in Fig. 5, there were four major components in the Citizen-Helper deployment for training exercises (in short, referring as Citizen-Helper training):

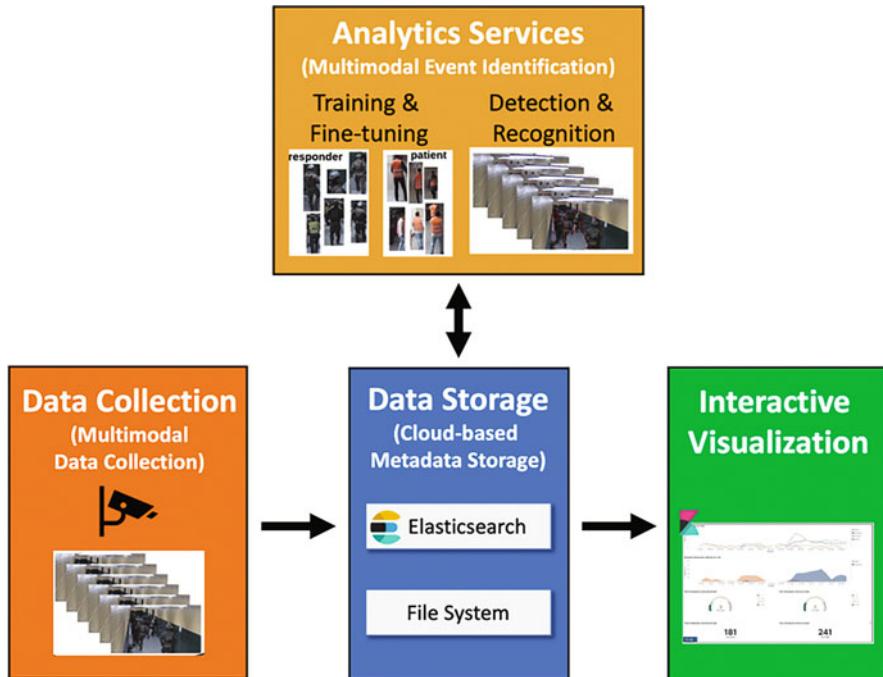

Fig. 5 The system architecture of the Citizen-Helper deployment for training exercises for video data processing for emergency preparedness and training debriefs

1. *Multimodal data collection:* The Citizen-Helper training system collects data from multimodal data streams from different sensing sources during a training exercise. These sensing technologies, including wearables, can be static at specific locations, such as IP cameras, occupancy sensors on walls, etc., or dynamic like drone devices and IoT sensors on equipment or tied to practitioners or other exercise participants, such as patients or victims.
2. *Multimodal event identification:* The system processes the collected semi-structured data in this component. The system tries to detect the events of our interests (defined with the involvement of practitioners in the design stage of the system) in the raw data that have been collected from different data sources using AI models corresponding to specific data modalities. For instance, in the active shooter response exercise, Citizen-Helper employed object recognition techniques to identify specific events such as the appearance of the wounded patient, person seeking rescue, first responder, etc. The system facilitates both supervised and semi-supervised learning algorithms to build and employ models for event detection.
3. *Cloud-based metadata storage:* The system stores metadata of interesting and nontrivial patterns of events that are continually detected by multimodal event detectors in a cloud-based database. We used Elasticsearch, as described earlier,

for faster search processing and retrieval of relevant information for an interactive visualization interface built using Kibana.

4. *Interactive visualization:* The system uses the interactive Kibana-based interface to visualize different insights for real-time performance analytics of trainees for training exercise instructors and incident commanders, for instance, patterns of time series for the specific periods, such as when interactions between a first responder trainee and a wounded patient happened and when trainees from different first responder teams met. Following the principles of human-centered AI design, the system provided interactivity and customizability for the training instructors in browsing the patterns. The system could efficiently handle different front-end interface changes per the user's filters when browsing such patterns on the dashboard interface in real time.

Overall, the Citizen-Helper system for training augments the learning experience of disaster management practitioners in the simulated training exercises by supporting instructors with multimodal data analytics for enhanced training debriefs. This presented application of the human-centered AI system design was demonstrated for specific AI technologies. However, the system design is extensible for data processing with other AI techniques, such as natural language processing to process audio communication of the exercise participants to provide more insights for enriching the training debrief discussions.

Challenges and Future Research Directions

We discussed in this chapter various ways in which humans can be involved in AI-based data analytics systems in disaster management. We identified several use cases of such a system that has been deployed in various real-world scenarios of disaster management phases. We used the Citizen-Helper system as an example to inform how human-centered AI system design can help mitigate the challenges across different scenarios for the requirements of practitioners. There are still many challenges in achieving the overall vision of human-centered AI system design to develop reliable, safe, and trustworthy systems. We identify three distinct challenges to inform future research directions to design and develop such systems for disaster management.

First, as noted in implementing Citizen-Helper for identifying risk and prevention behavior in the analysis of a pandemic, rolling out the implementation can take significant time due to the unavailability of the data to train the AI models. This delay should be minimized by adequately preparing for future disaster scenarios, and thus, preestablished collaborations with practitioners can be invaluable. It is crucial to collaborate with them in the system design process early on to inform the rapid adaptation of existing data processing pipelines from prior disasters in the case of a new disaster. One technical research direction to support this requirement for future work can be the exploration of rapid but interpretable domain adaptation methods (Krishnan et al., 2020).

Second, the previous use cases did not consider the ways to improve the quality of human inputs. In reality, humans can make errors, which gets reflected in the quality of the machine learning models trained in AI systems. Those errors are often caused due to either an incorrect or incomplete knowledge of the users (mistakes) or inattentiveness and memory decay of users for particular concepts (slips) (Pandey et al., 2022). As a result, the AI systems get induced by the errors made by humans, which results in poor performance overall. Thus, mitigating human errors is one of the promising future directions for research on human-centered AI systems for disaster management.

Third, due to the increased burst of data during an active disaster event, the disaster management practitioners might have limited time, however, a high workload to make sense of several events identified in the data. Consequently, it is essential to rank each event of interest in terms of its serviceability and decide on the optimal workload required given the limited time of practitioners, which does not hamper the overall recall of the events. Hence, there is a need to optimize both how many and how often the events need to be processed by disaster management practitioners to improve performance, while also taking care of the limited workload (Purohit et al., 2018a). Hence, we observe the necessity of creating more synergistic and collaborative approaches to jointly improve human and machine performance when designing human-centered AI systems.

To conclude, this chapter presented a detailed overview of human-centered AI system design and its advantages in disaster management by illustrating an example of Citizen-Helper system. Moreover, it discussed use case scenarios of a human-centered AI system design by taking several implementations of the Citizen-Helper as examples. Additionally, it described current limitations and challenges for future work on human-centered AI system design, which can help expand the use of the human-centered AI approach in future disaster management.

Acknowledgments Purohit thanks the Office of Research Computing at George Mason University for providing infrastructure resources to host Citizen-Helper and also the U.S. National Science Foundation grants (1657379, 1815459, 2029719) for partially supporting the underlying research behind the systems described here.

Abstract

Recent geospatial information technology developments have prompted researchers to utilize multi-sensor data for decision-making in disaster situations. Cultural heritage needs to be preserved as it reflects local characteristics and the knowledge of its creators. Cultural heritage, which is difficult to restore to its original state when damaged, should be the first consideration in a disaster. This study proposes a method of how geospatial information from satellites, drones, smartphones, and historical maps can help to make cultural heritage resilient to various disasters, such as earthquakes, wildfires (including human-induced), and flooding. The method how to integrate geospatial information for resilient cultural heritage in a given disastrous situation is a very critical process. In this study, the core role of geospatial

information for resilient cultural heritage is presented by applying the methodology presented here. The data acquired from multichannel imagery and historical maps can be formed into digital resilient heritage data, which enables timely access to decision-makers. Additional information can be derived from accumulated data through data integration processes and by extraction of the knowledge of ancestors encapsulated in cultural heritage. To verify this, we explored three Korean cultural heritage examples. We concluded that the proposed methodology is expected to contribute to maintaining the identity of cultural heritage and preserving its unique value by improving its resilience of cultural heritage.

Cultural heritage · Cultural resilience · Multichannel imagery · Historical map

Introduction

Every country is continuously trying to protect its people and national assets from disasters. However, it is always difficult to respond to disasters in the initial stage. This situation frequently happens because it is difficult for decision-makers to access situational information when a disaster occurs. With the development of various sensors from space to the ground, the basis for obtaining any information from the disaster site is being ready. It can be said that the foundation for preserving important national assets via evidence-based decision-making has been provided (Abate et al., 2022). The remaining thing is implementing the framework for using various sensors in actual situational awareness.

In this study, a framework is provided on how to continuously protect cultural heritage, an important national asset, by using images from satellites and drones to terrestrial images such as smartphones and CCTVs. In addition, historical maps are another vital source of information that reveal the location of cultural properties in the past. This study also investigates how the resilience of cultural assets improves when such historical maps are combined with more recent imagery.

Cultural heritage connects us to the past, provides valuable insights into our identity and evolution, and can play an important role in economic growth, poverty reduction, and sustainable development (Stanton-Geddes & Soz, 2017). If these cultural heritages are damaged, they cannot be returned to their original state, and their value is difficult to convert into monetary value. For this reason, cultural heritage has recently been included on the international agenda of disaster risk reduction. The Sendai Framework for Disaster Risk Reduction (SFDRR) recognizes the linkages in different aspects of culture, risk reduction, and resilience and helps preserve culture by providing a basis and policy environment for mainstreaming disaster risk management (DRM) (Stanton-Geddes & Soz, 2017). Therefore, it is important to protect cultural assets, respond quickly in case of disaster, and restore them to their original state in case of damage to build cultural heritage resilience.

The concept of resilience was developed by Holling in 1973 and has since been defined as “the ability of a system to absorb, utilize, or even benefit from disruptions and changes in order to be able to continue without any qualitative change in the structure of the system” (MacKee et al., 2014). In climate change adaptation, resilience is defined as “the ability of systems and their components to predict, absorb, accommodate or recover the impacts of hazardous events in a timely and efficient manner, including ensuring the conservation, restoration or improvement of infrastructure and functions” (IPCC, 2012). The main activities for building resilience in cultural assets may include providing alarms to prevent damage to cultural properties when a dangerous situation occurs, quick response activities to minimize damage, and restoration to maintain the original shape. Understanding specificity is essential to build resilience, but a holistic approach is more critical. A resilient system requires integrating various types of knowledge for learning (Folke et al., 2002; MacKee et al., 2014). Therefore, to improve the resilience of cultural heritage, a multidimensional approach that integrates various geospatial information with the expertise of stakeholders is required.

To increase the resilience of cultural assets for disasters is being actively carried out from the individual cultural asset level to the entire country or an international level such as the United Nations. In Japan and the United Kingdom, cultural assets are included to establish national and regional DRM plans (Stanton-Geddes & Soz, 2017). The EU tried to promote the resilience of cultural heritage through the ResCult project (“Increasing Resilience of Cultural Heritage”) as a platform for cooperation between government and nongovernmental sectors, emphasizing the importance of data accumulation on a large scale (Colucci et al., 2022). UNDRR (2022) published the “Disaster Resilience Scorecard For Cities: Cultural Heritage Addendum” to support the development of cultural-based and people-centered disaster risk reduction and resilience strategies integrated with cultural heritage and development policies, and the importance of generating a complete database of exposure and vulnerability of cultural heritage was emphasized, considering possible changes that can occur over time through climate change. Research on how to prepare for disasters by introducing new technologies to cultural heritage has been actively conducted conceptually and practically. Many studies are being conducted to apply new technologies, such as satellites, drones, and ground laser scanning.

Agapiou et al. (2015) prepared a risk map for natural and anthropogenic risk factors using remote sensing and geographic information system (GIS) techniques to evaluate the risks to the area where the cultural heritage is located. The PROTection of European Cultural HERitage from GeO-hazards (PROTHEGO) project (PROTEHGO, n.d.) aims to develop and validate innovative methodologies using InSAR and GIS technologies for the detection and monitoring of European cultural heritage exposed to natural hazards (Spizzichino et al., 2017). This methodology was applied to the 339 UNESCO World Heritage Sites in Europe, and by integrating these data with an existing geographic risk database, the most important cultural heritage sites across Europe were identified and prioritized. Korumaz et al. (2014) analyzed the potential of drones in analyzing, interpreting, and managing cultural heritage through a case study. Risbøl et al. (2015) performed change detection through time series data using airborne LiDAR.

The EU's FIRESENSE project presents the framework for how to protect cultural heritage from wildfire (CORDIS, 2022). This project emphasizes the fact that the cultural properties of the Mediterranean region are most vulnerable to wildfire, resulting in a lot of destruction. In this project, a new cultural asset management and supervision system was developed by integrating visible and infrared images, 3D geospatial information, and meteorological information.

Existing research has been applied to cultural heritage management using only fragmentary information obtained from satellite, drone, and GIS technologies or has focused on specific disasters. This motivates to build a framework to promote cultural heritage resilience using multi-sensor image information. In the case of a fire that occurred in the Notre Dame Cathedral in Paris in 2019, even though a fire safety system was built inside the cathedral, the initial response was operated only after a person directly checked the fire and reported it, not being able to extinguish the fire within the prime time. This event teaches us a lesson that research is needed to efficiently manage cultural heritage by acquiring data from various sensors and integrating these data to improve the resilience of cultural heritage.

Although the importance of integrated utilization of multi-sensor data is being emphasized in order to manage cultural heritages efficiently, research on the overall management system is insufficient. Korea's Cultural Heritage Administration (CHA) has also introduced a digital approach to all areas of preservation, management, and utilization of cultural heritages in 2021. In addition, in order to integrate and manage the repair history of cultural heritages, the "Cultural Heritage Repair Information DB Establishment and Repair History Management Integrated BIM Modeling" project is in progress, and the main contents include building a database for the integrated collection and analysis of repair records of cultural heritages and building BIM modeling to manage the repair history of cultural heritages. Therefore, there is a need for a method for the integrated utilization of recorded data and new incoming data.

This study examines how geospatial information from satellites and drones to smartphones and historical maps can help to make cultural heritage resilient to various disasters, such as earthquakes, fires (including human-induced), and floods. By integrating multiple sensors for resilient cultural heritage, we try to identify what role geospatial information and past information play in actual disaster situation. This study tried to verify the framework by applying the methodology to the cultural heritage in the Republic of Korea (hereafter "Korea") and analyzed the areas that could be improved. Through case studies, it is expected that the resilience of cultural heritage will be improved if continuously developing geospatial information technology is applied to cultural heritage and a large amount of data is accumulated.

Resilient Cultural Heritage Using Information from Space to Ground

Multichannel imagery refers to all presently available images. Image is a valuable source that many people can intuitively use and provide. However, there is a limit to confirming the data collected according to the type of sensor (satellite, drone, CCTV, smartphone,

etc.), point of view, data acquisition conditions, and the agency in charge as an integrated form of information. Collected data can have different data formats and types of extractable information depending on the type of sensor, and information collected from a single sensor in an emergency cannot be sufficient for decision-making. Therefore, it should be possible to integrate data collected from various platforms and sensors and extract information necessary for decision-making based on the integrated data. In the following, a framework is presented to use many of these images, and a methodology is suggested how to use them to build cultural heritage resilience. In addition, the framework is intended to suggest a way to restore or preserve cultural heritage even if they are not protected and damaged. In order to build cultural heritage resilience, the stages can be divided into the process of acquiring multichannel image data, constructing a digital data cube for location-based images, and extracting indigenous knowledge from data that does not contain location information (e.g., old map). This process can contribute to the construction of cultural heritage resilience. Figure 1 represents the overall picture of how this process can be operated and provided to the decision-makers.

In order to support appropriate decision-making, it is important to display and confirm information based on location information. Data collected for cultural heritage management purposes, such as monitoring the condition of cultural heritage, can be continuously accumulated in cultural heritage archives. Data accumulated in cultural heritage archives can be used for risk factor identification and restoration activities in the future. Data collected in emergency situations can be checked in real time by decision-makers in the display system, and data can be expressed in a form that can support decision-making through analysis such as change detection with existing data accumulated in cultural heritage archives.

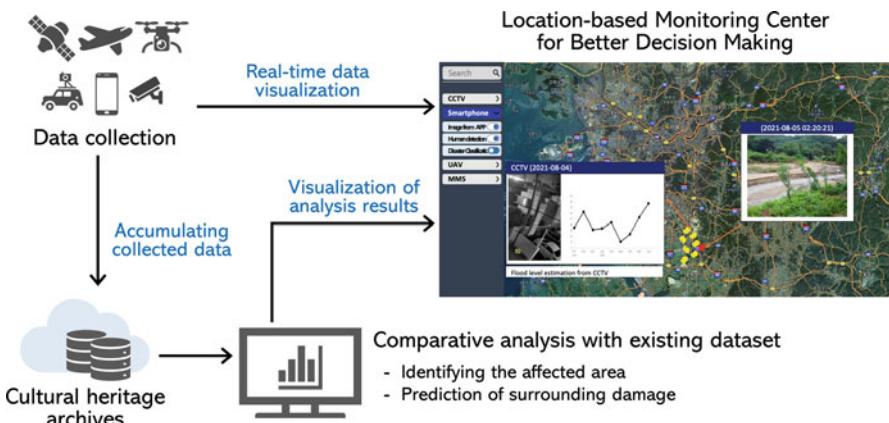

Fig. 1 Decision-making process using multichannel imagery

Multichannel Image-Based Data Acquisition

Multichannel can be divided into aerial sensors such as satellites, drones, and terrestrial image sensors. These multichannels have different characteristics and types of information acquired according to the sensor characteristics, as shown in Fig. 2. When using multichannel information, a hierarchical approach can be used. Through this, it is possible to acquire appropriate information according to the type (e.g., the size) of cultural heritage and the characteristics of the sensor. The hierarchical approach means that the received data is utilized according to the resolution of the provided image or information.

In general, satellite imagery can be effectively used for covering a wide area. However, there is a high possibility that the spatial resolution is likely to be low. Satellite images are generally defined in relation to their resolution, positional accuracy, aerial coverages, and spectral characteristics. Recently, there has also been an opportunity to quickly take images of the same area using geostationary orbit satellites or micro-satellites. To increase the usability of the satellite, it is necessary to develop an optimal operating technology that can acquire the same area quickly based on the characteristics and orbit of the satellite. Unmanned aerial vehicle (UAV, or drone) has the feature that it is possible to acquire information about the desired area rapidly. However, depending on the type of UAV, flight characteristics and types of mounted sensors are different. Therefore, it is important to consider the UAV platform first. In order to utilize the UAV in disaster situations, the first step is to define the overall specifications of the UAV platform and analyze the specifications of the latest platform.

UAV can be classified into various types such as multi-rotor, fixed-wing, and fixed-wing hybrid vertical takeoff and landing (VTOL). Various types of sensors such as camera, LiDAR, and RedEdge can be equipped on UAVs, and high-

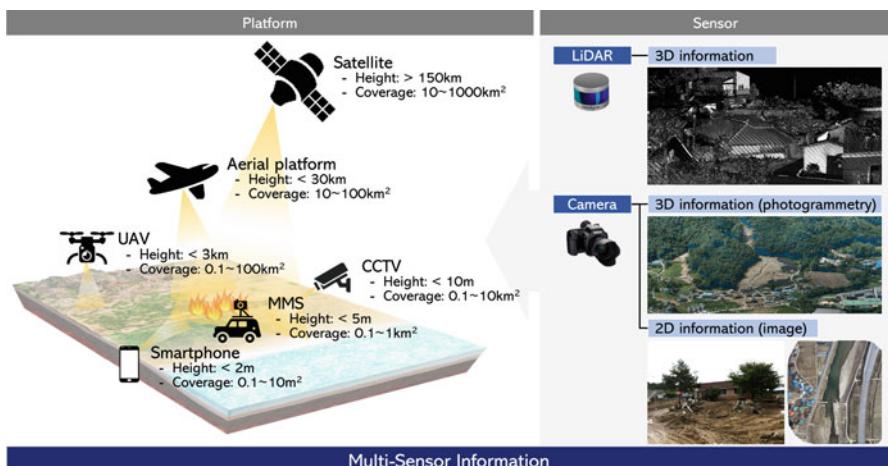

Fig. 2 Multi-channel image acquisition framework over a disaster site

precision orthoimages and 3D modeling are possible using photogrammetry techniques depending on the route plan. Research has been actively conducted to perform precise 3D modeling using data collected by UAV for major cultural heritages including UNESCO World Heritage Sites (Tache et al., 2018; Manajitprasert et al., 2019; Ulvi, 2021; Pepe et al., 2022).

Suppose satellite images identified the overall external force or situation for a spatially large area. The next step is to use a high spatial resolution and available spatial information acquisition method for a narrow area. According to the proposed framework, the initial situation is caught by using the surrounding CCTVs. At the same time, a drone is sent on-site to understand the overall situation. The field personnel can take images using a smartphone. The local government can dispatch Cultural Heritage Monitoring Vehicle (CHMV) to get detailed ground-based information about the site. CHMV can be equipped with sensors such as cameras, LiDAR, GNSS, and IMU, and through this, it can quickly collect precise data about the dispatched site. Compared to UAV, it has the disadvantage of being accessible only to places where vehicles can enter, but since the operating conditions are relatively less demanding and the operating time is longer, it is equipped with high-resolution sensors to quickly access the site and obtain precise data in an emergency.

Digital Heritage Cube Based on Positional Information

Information on the acquisition time, location, and acquisition sensor is required in collecting data. Based on this information, detailed analysis activities can be performed through monitoring of continuously provided on-site data. The amount of data acquired from the multichannel sensor in an emergency situation through periodic monitoring will be significant, but if proper management is not performed, it may be challenging to utilize the data. Therefore, the digital data cube for collecting location-based cultural heritage image data can be expressed as shown in Fig. 3. By accumulating and managing data according to the proposed digital data cube, it is possible for decision-makers to respond correctly and access desired data

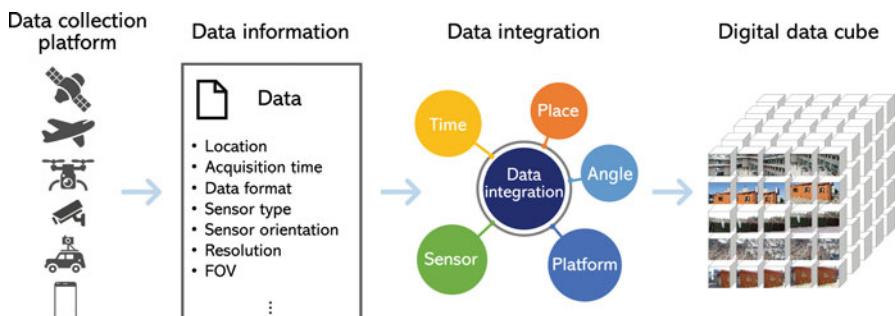

Fig. 3 Construction of digital data cube for resilient cultural heritage

in a timely fashion. Since the data accumulated based on the digital data cube includes location information, it is easy to integrate data obtained from various sensors. By periodically accumulating data on cultural heritage in digital data cubes, change detection analysis can be performed through comparison and analysis with previous data when an emergent situation occurs.

The digital data cube means organizing data composed of various formats collected from various platforms and sensors into one integrated form. Collected data has different formats, viewing angles, and resolutions depending on where, when, and how it was collected. Therefore, a process for integration is required to converge and utilize the data collected in these heterogeneous environments. The process of integrating data includes defining the collection location of collected data. For example, old maps recorded a long time ago may not have location information, and the types of sensor data collected, such as GNSS and IMU, can differ depending on the collection platform. In addition, since inaccurate location information can be collected depending on the data collection area, corrections may be required to secure accurate location information. Furthermore, to perform time series or comparative analysis between accumulated data, it is possible to accurately access and utilize the desired data only when the information on the acquisition time and acquisition location of the data is configured in the same format. Accordingly, the data integration process can include a process of converting collected data information such as location, time, and sensor information into a reference format. The digital cube built through this process can be defined mainly in three axes: time, location, and sensor.

Information Acquisition from Historical Map

Traditional knowledge systems embedded in cultural heritage can play an important role in disaster prevention and mitigation and thus contribute to more sustainable development (Jigyasu et al., 2013). In collecting data related to cultural assets, it is possible to discover knowledge about disaster damage, disaster preparation, prevention, and response included in historical records such as historical maps produced in the past. The historical map is representative visual data showing the appearance of the region and serves to represent the geographical knowledge of the time (Bae et al., 2019). In addition, the historical map contains various attribute information that can be used in the present or future. Figure 4 gives steps for incorporating historical maps with modern geospatial data based on location information (Bae et al., 2019).

Indigenous knowledge refers to local knowledge that is unique to a given culture or society, which serves as the basis for regional-level decision-making in agriculture, health, education, natural resource management, and other activities in the community (Boven & Morohashi, 2002). Sithole et al. (2015) state that regional knowledge is an essential factor that can increase the resilience of communities and should be complemented by measures to address the relevant human, social, and cultural factors that influence and render risks into disasters. Jha and Jha (2011) stated that integrating scientific or technologically enhanced methods with

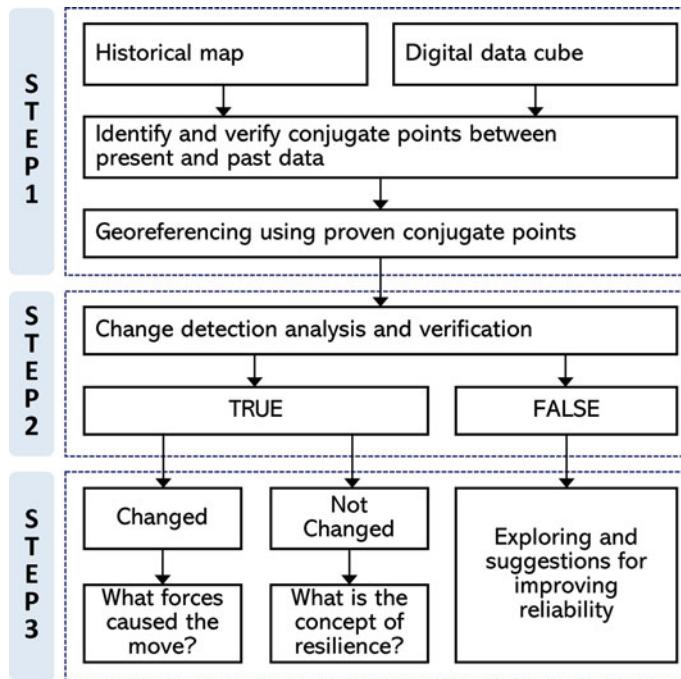

Fig. 4 Steps for incorporating historical maps and modern geospatial information

traditional knowledge provides a methodology for better disaster prevention and mitigation, preparedness, response, and recovery. Therefore, the digital heritage cube that was constructed with data both obtained from the multichannel sensors and the indigenous knowledge from historical records can provide an efficient framework for resilient cultural heritage.

Application of Resilient Heritage Cube to Real Cases

Forest Fire at Gangwon-do

The occurrence of wildfires has recently increased due to high temperatures throughout the year and an increase in the number of dry days in Korea. About 40% of the total forest area in Korea is coniferous forest, which occupies the most significant proportion, and is mainly composed of pine trees. Most of Gangwon-do's topography is mountainous, of which 43.4% is the mid-mountainous area between 500 m and 1000 m, with the highest proportion in the country. Good implications can be found by comparing the response to the forest fire in the past with the present response since this province suffers a lot of damage from frequent forest fires.

The forest fire in Gangwon-do, which occurred on April 4, 2005, caused a tremendous disaster due to continuous dry weather and strong wind. This causes to burn off 150 hectares of forest. To make matters worse, there was no information about the direction of spreading, causing Naksansa Temple and Dongjong of Naksansa Temple, National Treasure No. 479, to burn down. It took 1 year to investigate the damage to compensate the residents. However, in the case of the forest fire in Gangwon-do in 2019, active use of technologies such as satellite and drone imaging could contribute to rapid fire suppression.

It is worthwhile to compare the response to the forest fire of 2019 and that of 2005 at the same place and check how our proposed framework works. In the first stage of the framework proposed in this study, satellites, CCTVs, drones, and smart devices can be selected as usable sensors. It is difficult to predict the extent of the spread of forest fires, which depends on the influence of weather conditions, and thus continuous monitoring of a wide area is required. Since CCTV is continuously taking live images, it is easy to detect and analyze the spread of forest fire through continuous monitoring. Research has been conducted to apply deep learning techniques such as You Only Look Once (YOLO) (Redmon et al., 2016) and faster region-based convolutional neural network (Faster R-CNN) (Ren et al., 2015) to automatically and early detect a fire before it spreads based on CCTV images (Lee & Shin 2019; Lestari et al., 2019; Park et al., 2022), and Park et al. (2022) proposed a method of approximating the damaged area with weather data after detecting forest fire using an early fire detection model. In addition, damage can be reported through images taken with smartphones, which can enable damage analysis that cannot be detected by satellite and drones. As the use of social media has recently been activated, studies have been conducted to analyze disaster situations by crawling posts uploaded by citizens using smartphones (Alam et al., 2017; Wu & Cui, 2018; Fan et al., 2020; Belcastro et al., 2021). Disaster types can be classified using a deep learning model for images on posts, and the affected area can be estimated based on the location information of the classified images.

In the second stage, it is necessary to secure satellite imagery to determine the extent of damage in a wide area after receiving the report. At the same time, it is necessary to quickly approach the site by analyzing the fire truck access route through CCTV analysis. When deployed to the site, more detailed information about the damaged site can be obtained using drone images, and a fire suppression strategy can be established based on this. Studies have been conducted to identify the damaged area and severity using UAV images to detect collapse or cracks in structures or using UAV-based orthoimages for semantic segmentation based on deep learning technology (Kerle et al., 2019; Rahnemoonfar et al., 2020; Calantropio et al., 2021; Wang et al., 2022). In addition, the information acquired from the smart device makes it possible to acquire information in the blind spot. The CHMV equipment enables precise analysis of the damage after the fire is extinguished.

The third stage is to derive information for supporting decision-making by integrating the image information obtained from the multichannel sensors. Data acquired from satellites, drones, and CCTVs can show damage caused by forest fire from multiple perspectives. It is possible to analyze the damage status by

converging these data accurately. Precise data on the ground can be obtained using CHMV data for recovery, but in this case, it may not be easy to get information about the bird's-eye view. On the other hand, in the case of drones, since image is taken from above, information on the ground may be insufficient. In this case, it is possible to construct precise three-dimensional data on the damage by combining the two data. Chatzistamatis et al. (2018) removed all possible occlusions by fusing terrestrial LiDAR- and UAV-based 3D modeling to evaluate the damage to structures due to earthquakes. Cucchiaro et al. (2020) combined terrestrial LiDAR and UAV to better manage and protect agricultural terraced landscapes, an important historical heritage.

Improvements Through a Multichannel Approach

By coincidence, a large-scale forest fire occurred in Gangwon-do 17 years ago in 2005, and Naksansa Temple was destroyed by the Yangyang forest fire. Looking at the development process of the Yangyang forest fire, the fact that the process is quite similar to the wildfire that occurred in Goseong and other areas, along with the fact that the government has dealt with the crisis, can be compared in many parts. The difference between the two responses is as follows.

The first is to strengthen active collaboration between ministries. In the event of a forest fire, interministerial strategy meetings were held frequently, and a cooperation system among related departments was strengthened (MOIS, 2019). Second, the Korea Forest Service (KFS) sent a large helicopter resistant to strong winds to report the direction of the wildfire continuously and to evacuate residents quickly. Third, KFS requested satellite imagery of the forest fire area and announced the extent of damage and the degree of damage in a week (Fig. 5). This is the result of establishing an intelligent forest fire prevention and extinguishing system based on science and technology. Figure 5 is an example of analyzing regions damaged by the forest fire by comparing and analyzing aerial orthophoto or satellite images collected and produced before the event with drone images acquired after the event. Based on the image built before the forest fire, the changed area was identified in the drone image. Since forest

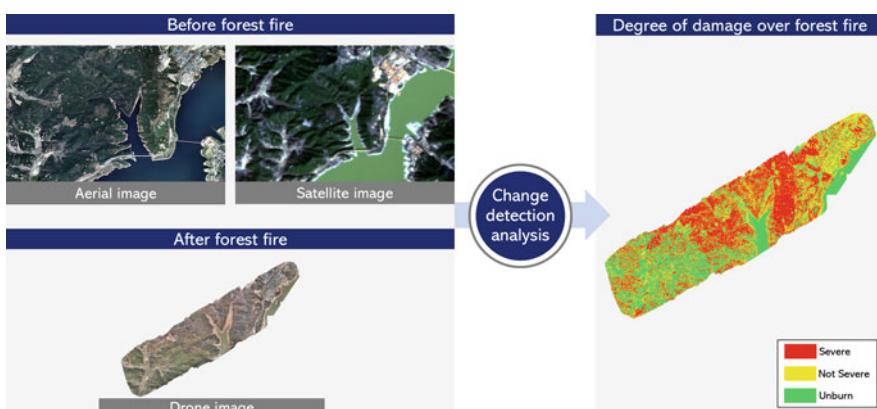

Fig. 5 Forest fire damage estimation from satellite, airborne, and drone imagery

fire prevention is crucial, the KFS has been promoting innovative forest fire prevention activities using forest drone monitoring teams since 2019. Smart CCTVs with sensors that automatically detect flame smoke are being distributed on the east coast of Gangwon-do, where there is a high risk of a large-scale forest fire.

Earthquake in Gyeongju City

The largest earthquake (magnitude of 5.8) ever to hit the Korean Peninsula occurred in Gyeongju at around 7 p.m. on September 12, 2016. Near the epicenter, Gyeongju City, and the surrounding areas, there were casualties; facility damage, such as cracks in and partial breakage of buildings; temporary communication disruptions; and minor damage to fences, roofs, and walls to 59 cultural properties. The significant cultural heritage impacts included the separation of the Jungjasuk of Cheomseongdae (Korean Treasure Number 31) and the fall of the stone Dabotap of Bulguksa. The cost of the damage to cultural properties was estimated at 5 billion won.

This was the largest earthquake to occur since the beginning of earthquake observation. This led to a review of comprehensive countermeasures for earthquake prevention to provide fundamental analysis and improvement plans for existing measures. The response to the impacts on cultural assets during the Gyeongju earthquake had four main aspects: information provision, initial and in-depth response, restoration, and acquisition of ancestors' wisdom.

When the earthquake occurred, accurate information on the situation could not be quickly communicated to the people. At the time of the Gyeongju earthquake, the website of the Ministry of Interior and Safety was out of order for 3 hours, and no disaster message was sent to the people until 9 minutes after the quake. Accurate and rapid information for not only decision-makers but also the affected population can contribute to appropriate response activities, such as evacuation.

Second, because of the risk of aftershocks, it is important to quickly identify the damage to cultural assets and take appropriate actions. Accurate measurements must be part of the initial response. However, in this case, the initial inspection was purely visual, and a meticulous inspection with precision measurement equipment was only performed later.

Third, the pre-event data constructed in advance can be used as essential data to restore cultural properties. For example, the Korea LX Corporation had acquired 3D data using terrestrial LiDAR and UAV after an earthquake hit Cheomseongdae on September 23, 2014. These data could be compared with 3D data using terrestrial LiDAR and UAVs after the 2016 Gyeongju earthquake. Analysis showed 0.4–3.4 cm differences in reference point coordinates, 3–5 cm in height values, and up to 1.6 cm in slope. When the type of damage can be expressed in a 3D-based quantitative manner, it is possible to calculate the 3D volume to facilitate recovery activities. This detailed quantitative analysis of the cultural asset damage played a crucial role in restoration decisions.

Fourth, acquisition and reflection on ancestors' knowledge can also aid the restoration. Cheomseongdae was built in the Silla era (AD 632–647) and was

designed with an excellent structural capacity to resist earthquakes. Specifically, it contained sand and gravel to absorb shocks. Advanced disaster response techniques were typically applied to cultural properties that have endured numerous disasters. Recognition and study of these historical techniques, drawn from the wisdom of our ancestors, can lead to further improvements supported by the greater precision and accuracy of modern data.

Improvements Through a Multichannel Approach

A better approach to an event such as the Gyeongju earthquake, based on multi-channel data and imagery, as described previously, would be as follows. In a situation where an earthquake occurs, damage mainly occurs in a wide area, and damage, such as the collapse of structures like roads and buildings, may occur. In this case, it may be challenging to obtain data on the site situation due to the difficulty of human access, and satellite and UAV images are highly utilized. Therefore, it is crucial to identify and manage risk factors before a disaster occurs using data collected on cultural properties and surrounding areas using satellites, UAVs, CCTVs, and 3D laser scanners. In addition, in the case of cultural heritage, changes may occur as they endure for a long time. It is possible to check for any changes in cultural properties and act appropriately by periodically collecting 3D laser scanner data. Lercari (2019) verified the usability of the surface change detection method using terrestrial laser scanner data acquired multiple times to monitor and preserve ancient buildings and confirmed that the change was detected with millimeter-level accuracy. Zaragoza et al. (2021) presented a method for performing change detection analysis by integrating a 3D model reconstruction using archive images and a 3D model measured using UAV.

When a disaster occurs, it is necessary to recognize the type of disaster and the damage situation quickly. CCTV installed for monitoring cultural heritage sites and smartphone images collected through citizen reports can be used first. After that, the damage range can be estimated using satellite and UAV images, and response activities can be supported based on precise field situation information. Appropriate response strategies should be established to minimize damage by integrating the characteristics of the affected area with the cultural properties located in the area. In an earthquake situation, unpredictable events, such as aftershocks, building collapse, or the spread of hazardous materials, can occur after the main quake. Therefore, continuous on-site monitoring is needed. In particular, it is important to anticipate where additional risk exists.

After the disaster is over, it is necessary to confirm the damage to the cultural property and determine the need for recovery or restoration activities. First, the damage range can be estimated in a wide area through displacement analysis using SAR satellites, and then precise damage information can be extracted using CHMV and 3D laser scanners. Such data can contribute to the accurate detection of damage, especially in areas with high potential for collapse, and support appropriate recovery or restoration activities by fusion with risk analysis and risk assessment results.

Knowledge Acquisition from Recent Images and Historical Maps

The overall methodology for studying the resilience contained in cultural heritage through linkage with historical maps and time series geospatial information was presented in Fig. 4. In the first step, geometric correction is performed on the historical map of the 1870s and the time series geospatial information after 1917 for comparative analysis. Since the primary purpose of this case study is not an in-depth analysis of geometric correction, polynomial rectification was used for two-dimensional linear affine transformation. The second step is to determine whether there is a change in cultural heritage that was actually located on the past map through the analysis of the numerical results of geo-referencing. At this stage, it is determined whether the cultural heritage location is changed or not. If there was a change in position or loss, it was judged that some external force would have occurred on the cultural heritage, and the cultural heritage could not have endured it. In the third step, knowledge of what external forces (e.g., earthquakes, floods, etc.) have occurred is tracked through historical facts, and if such external forces have not changed, we try to find out what lessons the cultural heritage can give us.

The area to be studied is Gongju, Chungcheongnam-do, and various designated cultural heritages such as treasures, historical sites, and scenic spots are located in this area. In this study, the historical map of Gongju (Gyujanggak, 10405), which is believed to have been produced in 1872 by King Gojong, was used to extract geospatial information using a historical map (Yoon, 1995). The location (address) data of the cultural property was used to confirm the location of the cultural property, and the data used as a reference point to perform geometric correction of the public notice map was used as an orthogonal image produced in 2016.

In the late Joseon dynasty, two types of maps were developed, such as a plan type and a painting type, and it can be seen that the accuracy is higher than that of the current map (Lee & Cho, 2014). The oldest data used in this study is the map of Gongju-mok, a local map created in 1872 in a pictorial manner (Fig. 6). In the case of a map written in a pictorial style, the accuracy is much lower than that of actual measurement, but there is an advantage that the entire town can be viewed as a picture map on one side. Local painters were mainly mobilized to create the pictorial map, and although they were not able to produce the map well to the actual scale, it can be seen that they did an excellent job of depicting the landscape and humanistic image of the entire village by utilizing their skills in real-world landscape painting.

Figure 7 represents the time series of major cultural heritage adjacent to the Geum River. All data except for the 1872 historical map were downloaded from the land information platform operated by the National Territory Information Platform (2019). The historical map of 1872 was downloaded from the website of the Kyujanggak Institute for Korean Studies. Other data sets were an aerial image of 1:20,000 without geo-referencing taken from 1966 (studied every 10 years from 1966) and an aerial image of 1:5,000 produced in 2016 for use as a reference point. Also, 1:25,000 topographic maps were also used after 1966, which were made with

precision using aerial images. Through this, time series data were integrated around the same map coordinate system, and the map change according to time at the same location can be confirmed.

In Fig. 7, the parts marked in red highlight the nationally designated cultural heritage. Area A is Gongsanseong Fortress designated by the state No. 12, area B is Gomanaru (Cultural Heritage No. 21), area C is Songsan-ri tomb group (tomb of King Muyeol, tomb of King Muryeong, Cultural Heritage No. 13), and area D is the

Fig. 6 Map of Gongju-mok. (Source: Gyujanggak)

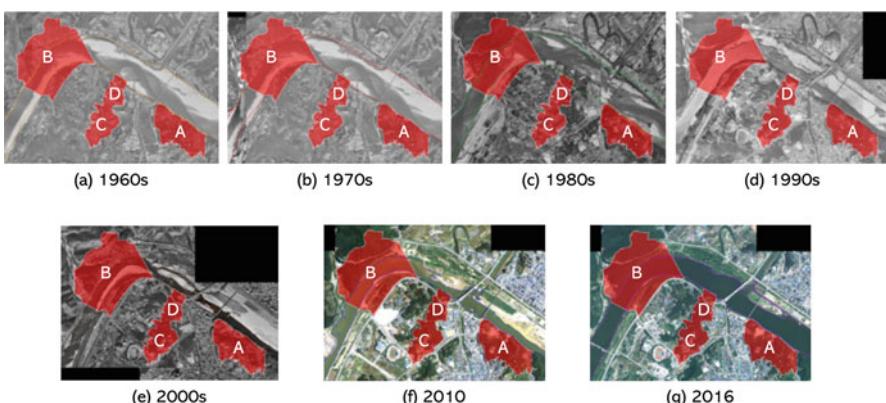

Fig. 7 Major cultural heritage locations overlaid with aerial images after the 1960s

ruins of Mt. Jeongji (Cultural Heritage No. 474). In the case of a historical map, it is helpful in understanding cultural heritage and the local conditions in the past. From time series, it is possible to distinguish between lost cultural heritage and preserved one. The Korean Peninsula has suffered a lot of damage from typhoons almost every year. Infrastructures around large rivers have suffered a lot of damage. As such, if cultural heritage remains in its old location over time and is preserved to this day, it can be said that the site has resilience. This insight gives the wisdom of our ancestors about disaster resilience in the past.

Conclusion

With the recent development of technology, the necessity for cutting-edge technology is increasing in disaster and cultural heritage management. Once damaged, cultural heritage is complicated to restore its original form. Thus, it is essential to manage cultural heritage well through periodic monitoring and a well-designed framework. However, most cultural heritage is monitored using a single sensor, causing a limitation to protect cultural properties in emergencies. In this study, a framework for improving the resilience of cultural heritage was proposed based on multichannel imagery and traditional knowledge in terms of disaster management.

The framework proposed in this study is divided into three steps. First, selecting a proper sensor for the given situation is necessary since each sensor has different characteristics. Second, we need to determine at what stage of disaster management the selected sensor should be utilized and what kind of information should be acquired using the selected sensor. Third, the data obtained from a single sensor needs to be integrated with other available information. Since each sensor provides different pieces of information, more diverse and accurate information can be obtained by integrating multiple data sets.

This three-step framework was applied to three cases of the actual Gyeongju earthquake, the Gangwon-do forest fire, and the use of historical maps in Korea to verify the possibility. Recently, various sensors have been used to respond to disasters with the rapid development of technology. However, a framework that utilizes appropriate sensors at the right time based on an analysis of available multichannel sensors needs to be selected and applied. In fact, it is confirmed that rapid response activities can be carried out compared to similar cases in the past. Damage can be reduced through faster and more accurate data acquisition when the framework proposed in this study is applied.

The proposed framework is expected to contribute to maintaining the identity of cultural heritage and preserving its unique value by improving its resilience of cultural heritage. The multi-sensor data collected on cultural heritage during normal times and disaster situations can also be further applied to various applications, such as cultural heritage exhibitions and training simulations.

Abstract

Tethered aerostats typically reach 4000 m above ground level. They are affected by winds. With waveguides in tethers of antenna-bearing aerostats, emergency power can be beamed in relays from other aerostats or ground stations. Free-flying aerodynamic High Altitude Long Endurance (HALE) vehicles offer faster response. Solar-powered Flying Leaf (FL) aerodynamic HALE platforms enable meteorology, remote sensing, and solar reflection planet-wide, with potentially unlimited endurance. This new capability complements tethered aerostats and self-propelled lighter-than-air platforms. FLs fly continuously between 20 km and 32 km altitudes, with imaging and broad area coverage, able to stay well above weather. Some sensors can see through clouds and rain. Autonomous and navigating using satellites, the FL system stays up 24-7 and serves as a network connectivity platform. It can see into deep valleys or to a 500 km horizon over oceans. Production launch and monitoring sites are spread worldwide, so they are readily available. Given the wide range of operations, international collaboration is integral to FL architecture, with ground observation and data channels pre-cleared. Essential points have been proven in simulation, ground and flight tests. This chapter

Introduction

The January 15, 2022 explosion of Hunga Tonga volcano in the south Pacific Ocean poses a challenge test case to emergency response capabilities. The shock wave from the explosion reached Hunga Ha'apai island shortly after 5:19 PM through the ocean, probably killing most sea-life on the way. The shock in air reached a few seconds later, flattening many buildings, causing concussion and burst eardrums to many who were not injured by falling debris. The tsunami arrived at Tongatapu by 5:30 PM, the water level rising 2–3 m (Schäfer et al., 2022). Wave heights up to 17 m completely inundated some islands. Many buildings were destroyed. Numerous islanders, already stunned by the shock wave, were swept into the ocean beyond, while others were pulled back into the ocean by the backwash. One disabled islander, swept off the tree to which he had clung for safety, swam for 27 h and got back to land. Although the explosion was seen from Space and reported within minutes, triggering Tsunami warnings all over the Pacific Ocean, it was over 48 h before the first airplane arrived for initial damage assessment. Satellite imagery over islands as far as 100 km away, where towns were devastated, came 4 days after the event, with no other communications. Much later the airport runways were cleared, allowing cargo planes to bring help.

The Indian Ocean tsunami of December 2004 also caused similar devastation and swept many people out to sea. Some were able to survive. The Indian Navy responded very fast and saved many lives near mainland India and Sri Lanka; but such help was not possible in Car Nicobar island 1000 km away, and near the epicenter in Indonesia.

The two concepts explained in this chapter address our ability to bring useful help much faster in such disasters. The Powered Aerostat is a relatively old concept. The modern aerostat has enough propulsion to maintain station in moderate winds, and floats as high as 4000 m. Solar photovoltaic-powered High Altitude Long Endurance (HALE) aerodynamic platforms are able to fly free and stay aloft for long periods. A variation on HALE is the Flying Leaf vehicle architecture. They fly free between 30.5 km and 20 km above sea level, and can counter winds of up to 50 knots. While neither aerostats nor HALE vehicles can directly deliver rescue supplies, they can reach disaster areas within hours if not minutes, and stay on station, using high-resolution sensors and wideband communications to facilitate timely rescue. They can guide smaller UAVs swiftly and accurately to deliver rescue and aid. Operational

knowledge and regulations are already in place for aerostats, while HALE vehicles are now routine in military reconnaissance and law enforcement. The FL architecture is compatible with existing Air Traffic Control and Space Law, so that Disaster Response functions can be naturally integrated with its control infrastructure.

Aerostats

Aerostats are Lighter Than Air (LTA) vehicles that float in air due to buoyancy. The term merely means that lift is due to buoyancy as opposed to aerodynamics, not that it stays in one place. A subset is vehicles tethered to stay above one location. The term aerostat is now reserved for these, as opposed to airships that travel. Even tethered aerostats use some aerodynamic propulsion and lift generation to counter winds. Today's aerostats include balloons, but most are much larger than hot air balloons: they have semi-rigid structure and a shape that reduces drag and even generates lift in winds. Tethers, typically 3 to provide position stability, are Kevlar-covered flexible tubes that carry power and the gas used to fill the gas envelope. Since aerostats do not carry humans, hydrogen can be used rather than more expensive and heavier helium. Electric power operates propellers, enabling aerostats to counter winds without unduly stressing tethers. These propellers can also move an aerostat between locations. Figure 1 shows an aerostat moored at the ground.

Aerostats find use in warning about impending avalanches (Raina et al., 2009) and mudslides as well as continuously monitoring areas and low-altitude airspace (Sangole et al., 2006). They have been used in India as inexpensive, re-locatable wireless communications platforms (Gawale et al., 2008), with 7.5 km useful signal radius and half the cost of a communication system based on towers. Aerostats have also been used for aerial imaging (Kanoria, 2010), remote sensing (Vierling et al., 2006), radar (Chang-sheng & Pan-feng, 2007), visual and infrared monitoring

Fig. 1 Tethered Aerostat Radar System. TARS. Courtesy US Government, Customs and Border Patrol

(Ram & Pant, 2010), traffic monitoring and control (Peterson, 2005), relaying electromagnetic signals (Relekar & Pant, 2002), generating wind power (Lansdorp & Williams, 2006), and collecting solar power from above the cloud layer. Solar power generation above the cloud layer using aerodynamic kites (Williams et al., 2008) may also be used with aerostats at larger scale regardless of winds.

Large aerostats are used in the United States Tethered Aerostat Radar System since 1980, by the US Customs and Border Protection force, Air Force and Coast Guard. These include aerostats tethered as high as 4600 m with a single tether, and those that can carry 1000 kg payload. An upper chamber carries helium and a lower chamber is pressurized with air. The hull is made of polyurethane coated Tedlar fabric. A diesel electric generator with a 100-gallon fuel tank powers a propeller. Volume is as large as $12,000 \text{ m}^3$, tether 7600 m long, payload 1000 kg and look-down radar has a maximum detection range of 400 km. At present, aerostat usage in the USA is coordinated with detailed operational information (Security, 2013) by the Department of Homeland Security.

An important variation of aerostats is the emerging cargo transport system using airships. Such vehicles enable delivery of rescue and relief supplies and equipment to areas where aircraft runways, road and rail service are unavailable. A vehicle developed circa 2000 called Cargo Lifter CL160, was 260 m long, 65 m in diameter, 82 m high and cruised at 90 kmph, carrying 160MT of cargo. It was intended to carry items that were too large and heavy items too unwieldy for highway transport, upto 10,000 km. One anticipated use was to carry enough food for 25,750 people for 14 days. It used 8 turboshaft engines each driving a 6 m propeller; 4 for cruise and the rest for maneuvering. Other designs are being developed by the US Armed Forces (Manikandan & Pant, 2021) and for humanitarian relief (Dorn et al., 2018).

Beamed Power Application

A proposed variation is to use the gas envelopes of aerostats to house receiver and transmitter antennae. Electric power converted to high-frequency microwave (or millimeter wave) beams is sent up to an antenna through waveguides to an altitude of roughly 4000 m, transmitted across to other antennae in aerostats, and sent down to the ground via their tethers. Such an architecture has been proposed in (Komerath et al., 2012) for emergency response. The converter equipment and other emergency tools would be carried as a slung load as the aerostat travels to the disaster area, at speeds of up to 100 kmph. Once over the site, the payload is winched down along with tethers. Once moored, beamed power is received through the antenna and conveyed through the waveguide in the tether. Alternatively, conversion equipment could be installed inside the aerostat, and a small amount of power transferred at line frequency through wires. Beamed transfer at above 4000 m altitude incurs little loss in the 145GHz and 200–220 GHz bands. The US Air Force has adopted such a concept to supply power to forward bases, avoiding ground transit of diesel generator fuel over hostile terrain.

Power beaming is still its infancy. Experiments in the 1980s demonstrated powering toy helicopters using beamed power, but scaling up faces 3 hurdles. Firstly, the diffraction-limited product of diameters of the transmitting and receiving antenna is proportional to the square of the distance between them, and to the wavelength of the beamed radiation (or inversely proportional to frequency). A small transmitter requires a large receiver and *vice versa*. The diameter of an antenna that can capture up to 94% of the incoming beam is given by the Frees equation:

$$D = \left(10.4 \frac{Rc}{f} \right)^{\frac{1}{2}} \quad (1)$$

A second problem is that vibrational transitions of water vapor molecules absorb microwaves at 10.3 GHz and its harmonics. This forces choice of beaming frequency to be well below 10 GHz, while avoiding frequencies reserved for Mobile Phone communications. The antenna size becomes too large in this range for any significant beaming distance. At frequencies above 10GHz, scattering and absorption by Oxygen and Nitrogen becomes large, but there are a few windows of high transmissivity (Liebe & Hufford, 1989). The window between 200 and 220 GHz is an ideal one. Astronomical observatories located at altitudes of 3000 meters and higher, have shown transmission through dry air of over 90% of that in Space. Line-of-sight horizontal transmission at 4000 m is therefore quite efficient, over dozens of kilometers. Aerostat-based power reception on a large scale will become attractive when Space Based Solar Power systems are brought on line.

A third problem is the inefficiency of conversion by present technology, to and from millimeter wave frequencies such as 30–300 GHz. The above discussion of beam size might suggest going to optical frequencies offered by lasers. Conversion to infrared laser beams can be as efficient as 39% from direct sunlight or from wall plug power, but conversion back to line frequency or DC awaits research breakthroughs. Present international laws restrict the use of high-powered lasers in Space.

Aerostat design is driven by tether mass and weight of the propulsion system needed to counter drag on ethers and aerostat at design wind speed. Aerostat drag coefficient C_D based on maximum frontal area is estimated using empirical expressions given by Konstantinov (2003), validated against a wide historical variety of LTA craft. In Eq. 2, L is aerostat length, A is slenderness ratio and U_∞ is wind speed relative to the aerostat:

$$C_D = \left(0.5354 + 0.0305(A - 5.55)^2 \right) (U_\infty L)^{-0.21} \quad (2)$$

High Altitude Long Endurance (HALE) Vehicles

A new class of vehicles has been enabled by the advancement of solar photovoltaic (PV) power generation technology. HALE vehicles are generally heavier than air and supported by aerodynamic lift. Nearly all successful designs so far are fixed-wing

monoplanes, with PV cells covering much of the wing upper surface. The requirement of long endurance dictates the use of high Aspect Ratio. If the wing span (distance between wing tips) is b and the planform area of the wing is S , the Aspect Ratio AR is defined as

$$AR = \frac{b^2}{S} \quad (3)$$

Where the wing is rectangular, AR is simply the ratio of the wing span to the wing chord. High AR means long span and small chord, which makes such vehicles susceptible to bending and twisting oscillations. The requirement to fly at high altitudes at fairly low speeds forces these vehicles to be built with extremely low-weight materials. During the daytime, solar power is adequate to keep the vehicle aloft. Night-time flight uses some form of power storage, which may use hydrogen fuel cells. While HALE vehicles have demonstrated continuous flight for up to 3 months, they cannot claim indefinite endurance because of the use of some form of expendable substance such as hydrogen.

HALE vehicles enable quick response in emergencies if they are located in proximity. They can carry optical and other sensors and serve as communication platforms. Staying at high altitude, they do not interfere with other air traffic. Griffin (2000) studied application of HALE vehicles to emergency response in the context of Canada. They found applications in several aspects: “As remote sensing or surveillance platforms that can stay in a local region for a long time, (aerodynamic HALE vehicles) can perform high-resolution, high-continuity observation and surveillance of emergency situations.” HALE vehicles carrying search and rescue transponders can also coordinate search and rescue. They can also serve as navigation/ radio location platforms.

The Flying Leaf Architecture

Earth’s atmosphere is retaining heat at approximately 2.92 Watts per square meter of surface area. Concern about this warming trend drives the urgency of collecting data over the entire planet. The Flying Leaf (FL) architecture summarized here is a growing approach to satisfy the need for such data. It consists of solar photovoltaic-powered, ultralight, aerodynamic lifting surfaces that float at low speeds between 20 and 30.5 kilometers MSL, able to stay up indefinitely. The same vehicles will also provide a rapid scale-up option when approved, to directly reduce solar heat input to the atmosphere in a controlled, reversible manner. This satisfies all concerns expressed by the US National Academy of Sciences (NAP, 2021) about projects that reflect sunlight. FLs provide a capability to respond quickly to disasters over parts of our planet that are far from industrial centers. It is part of the Glitter Belt architecture proposed to respond to Climate Change and sea level rise (Komerath et al., 2021).

A Flying Leaf (FL) is a solar photovoltaic (PV) propeller-driven flying wing (HALE) aircraft, with a large ultralight reflector sheet that is stretched and supported by its own aerodynamic lift. A crucial feature is the ability to stay above controlled Class E airspace (18,288 m or 60,000 ft. above MSL) through a night of at least 12 h duration without storing power for propulsion. This is possible when the Wing Loading, defined as the ratio of vehicle weight to its lifting planform area, is not greater than $1.25N/m^2$ nor the zero-lift drag coefficient above 0.02. The former is achieved by ensuring that the majority of the lifting surface is comprised of ultra-thin sheets, nominally of 25-micron thick Aluminized Mylar. To avoid reflecting nighttime radiation downwards, the bottom surface is black. The frame that holds the sheets is made of carbon fiber composites. Present designs (Komerath et al., 2021) show Flying Leaf vehicles with 752 m span and 32 m chord, supported by 3 solar-PV powered Flying Leaflet biplanes, each of 32 m span.

With such dimensions the FL cannot be launched or retrieved in assembled form. The deployment cycle shown in Fig. 2 is as follows: Flying Leaflets (FLTs) take off from small clearings at speeds on the order of 5 m/s on calm summer mornings. They climb to 30.5 k (100,000 feet) MSL within 8 h. As an FLT rises above the weather, it partially extends the rolled-up Mylar sheet carried as the upper wing of the biplane, along a 32 m x 32 m frame. Along the way to 30.5 km, each FLT carries out rendezvous with 10 others, forming an FL. The 11 sheets are fully extended to 32 m. Eight of the 11 FLTs then detach, leaving the upper frame supporting the FL sheet, and return in a swift dive to landing before dark.

The requirement to stay up without power through a 12-h night, comes from the anticipated Summer Follower missions. FLs are anticipated to operate in swarms, maintaining position and communication with each other, with spacecraft, and with ground stations where possible. Each one carries up to 3 instrumentation payloads,

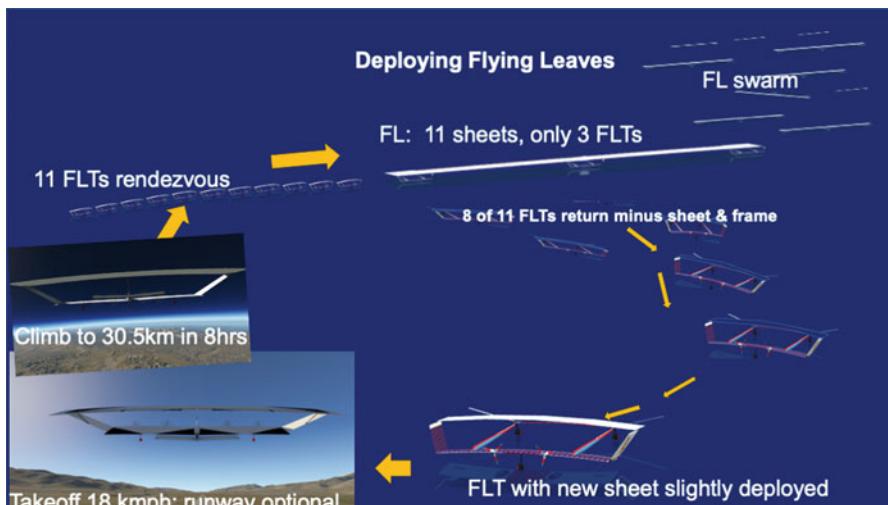

Fig. 2 Deployment of a Flying Leaf swarm. By permission of authors

slung by tethers and/or carried above a supporting FLT. In addition, antenna structures are woven into the sheets, to acquire data from above and below. From 30.5 km, the horizon is over 500 km away; however data may be relayed between FLs or between FL swarms with much higher bandwidth through the thin upper atmosphere, before being transmitted to ground stations.

Regulations and Support for Emergency Systems

Aerostats are included in the list of authorized equipment (FEMA, 2022) of the US Federal Emergency Management Agency under “03OE-07-STAT - Aerostat, Tethered (Balloon).” Key components are “a balloon, semi-rigid or rigid structure filled with lighter-than-air gas, a means for transporting the system, such as a truck and/or trailer; a mooring station for controlling the inflated aerostat envelope prior to launch; a launching/ mooring platform; tethers for mooring the aerostat envelope to ground equipment and transmitting power and data; winches for letting out, pulling in, and adjusting tether tension; and automatic or manual deflation devices. A variety of mission-oriented and tactical equipment include: high-resolution video cameras, electro-optical/infrared (EO/IR) sensors, communication/network repeaters, acoustic detectors, and radar. Tethered aerostat products may also include a ground control station for media storage, data transmission, and system management functions.”

In 2020, the Wabash Heartland Innovation Network (WHIN) announced a rural broadband communications network using aerostats at 1500–2000 feet (500–670 m) above ground level. In 2019 AT&T Inc. announced FirstNet, an emergency communication system would add 55-foot aerostats flying at 1000 feet (330 m) in winds up to 50mph (80 kmph) for up to 2 weeks.

Aerostat tethers pose a hazard to other craft, requiring a 2–3 nautical mile (3.65–5.47 km) flight restriction around a moored aerostat, from the ground to 4600 m above mean sea level (MSL). Small UAV rescue operations within this region may be permissible under special circumstances.

Flying Leaf vehicles are expected to be subject to the same regulations as other ultralight craft and High Altitude Long Endurance (HALE) aircraft. They do not nominally require Air Traffic Control permission once over Flight Level 600, which is 18.8 km (60,000 feet) above Mean Sea Level. However a new set of regulations is expected to be formulated by the United Nations to enable operation above the terrain of different nations, modeled similarly to Space Law. Regulation is expected through the International Civil Aviation Organisation.

ICAO’s Upper Airspace Working Group (UAWG) is an industry organization within the Aerospace Industries Association (AIA). They recommend (Hansell, 2019) the following key principles to develop risk- and performance-based regulatory initiatives:

1. Uniform airspace organization and management principles everywhere and at all levels of density, with consideration of traffic;

Table 1 Comparison of aerostats, lighter-than-air cargo transports, HALE craft with expendables, and Flying Leaf vehicles

Technology	Aerostat	LTA Cargo	HALE with expendables	FL
Altitude, km	4000 m	2-Jan	20–25	20–31
Speed	0–30 m/s	0–30	0–30	0–30
Operation Range, km	200	10,000	200	Indefinite
Endurance, hrs	Days	Hours	Months	Indefinite
Optical Horizon, km	400	200	400	500
Communications	Antenna inside	GPS, aircraft	Antenna	Antenna array
Payload Delivery	Initial package	Large	0	0
Deployment Difficulty	Low	Moderate	Runway; cal sunny	Field; calm sunny morning
Regulatory Agencies	Tether hazard		ICAO Above 60 K feet	ICAO Above 60 K feet
Comments/Future	Beamed Power Relay	Military Logistics lead		Meteorology; remote sensing; Solar heat Reflection

2. Airspace management to accommodate and optimize diverse and dynamic flight trajectories;
3. Complexity of operations may pose limit flexibility; equitably minimize impact of segregation of vehicle types by airspace organization;
4. Monitor airspace use to accommodate varying requirements;
5. For operations over 24 h, airspace reservations planned, with changes made dynamically. Like today, accommodate unplanned requirements;
6. Structured route systems only where required to enhance capacity or avoid limited-access and hazardous areas. Flexible as practical (Table 1).

Conclusions

Aerostats are established and growing in capabilities. They have the important advantage of being able to deliver aid to the ground while staying aloft for rescue imaging. In some cases it may even be possible to lower lifelines to people to keep them afloat until other help arrives. Even as they arrive, aerostats can be looking ahead for survivors, reporting damage and coordinating assistance. However, they are very susceptible to weather. In the Tonga volcanic eruption case, ash fall would have rapidly degraded and perhaps downed aerostats. In addition, their range of operation is limited, and it is unlikely that aerostats will be up and ready to approach a disaster area within a few hours.

The value of aerodynamic HALE vehicles in emergency response is already recognized. However, most HALE craft are limited to a few weeks of endurance at best. Thus, it is hard to imagine that sufficient numbers of HALE aircraft can be fielded all over the planet, to provide swift assistance in any area.

FLs are a new capability under development, with expected potential in disaster avoidance and response. They are uniquely able to loiter and travel over remote ocean areas that are inaccessible to meteorological airplanes, while traveling much slower, and much closer to the ground, than spacecraft. In the two case studies mentioned at the top of this chapter, availability of FLs would have made a big difference in saving lives and accurately directing delivery of aid. Such disasters may be expected to occur in future. As sea level rises, island communities are increasingly at risk even from major weather events, not just seismic events. The ability to suspend sensors from FLs while staying above weather and ash clouds puts even more important life-saving tools in the hands of rescuers. In clear weather and with air traffic control clearance, FLs can come down much below 18 km altitude temporarily.

Abstract

The recent literature reports several practical and important use cases of social media informatics where artificial intelligence (AI), machine learning (ML), and other relevant technologies are employed to analyze human sufferings and infrastructure damage in natural disasters. While the textual content of social media platforms conveys relevant and useful information during a disaster, social media imagery content has also been proven very effective in analyzing the scale of damage to infrastructures such as roads, bridges, and buildings. Moreover, disaster-related visual content could also be analyzed to extract people's

perceptions, emotions, sentiments, and responses to disasters, which can help different stakeholders, such as humanitarian organizations and policy-makers. Assessing such aspects of disaster events requires effective and efficient image processing methods to process a large amount social media content. This chapter reviews state-of-the-art techniques and shows their utility in processing social media image streams during disaster response for a diversified set of applications. It also highlights the key applications, challenges, available shared resources (datasets and models), tasks, and future research directions. This chapter will provide a ground for future research and a good starting point for the researchers in the domain.

Introduction

During emergencies, social media platforms have been widely used for information dissemination, damage assessment, and monitoring rescue operations. These platforms provide instant feedback to different stakeholders, such as public authorities, news agencies, volunteering/humanitarian organizations, the general public, and policy-makers on the scope of the damage. On one side, their ability to have access to a wide range of audiences worldwide makes these social media platforms a better choice for information dissemination more quickly to a larger population. On the other side, they allow citizens to post and share updated reports in the form of multimedia content from the ground. This concept of crowdsourcing and public journalism has been widely explored in emergency situations where news agencies and public authorities are unable to collect and report information (Said et al., 2019). The information from citizens is extremely beneficial to first responders, decision-makers, and practitioners who could exploit this exhaustive and widespread data to better assess the situation and guide the decision-making process (Alam et al., 2018a). As social media content has proven to be effective in facilitating diverse stakeholders, there has been growing research interest in developing computational methods and systems to better analyze and extract actionable information from social media content (Alam et al., 2019). The literature already reports several such systems deployed during disaster events (Imran et al., 2014). For example, AIDR (Imran et al., 2014) (<http://aidr.qcri.org/>) system has been used during major disaster events to collect tweets, classify them, and provide a visual summary.

Among different social media platforms, Twitter has been widely used due to instant access to timely multimodal information (i.e., textual and visual), which is crucial for different stakeholders especially government and nongovernment humanitarian organizations (Said et al., 2019). The earlier research efforts in crisis informatics are mainly focused on textual content analysis, which includes classification

of tweets, clustering them to group similar tweets, visualizing into timelines to show trends, geotagging them onto maps to look at the impacts, and visualizing topics, sentiments, and other aspects over time (Said et al., 2019). Lately, there has been a growing interest on the imagery content analysis (Alam et al., 2020; Nguyen et al., 2017b; Weber et al., 2020). The key applications for disaster-related social media imagery include severity assessment and identification of damage (Nguyen et al., 2017b), filtering humanitarian information (Alam et al., 2018a), crisis incident detection (Weber et al., 2020), and detecting disaster events (Alam et al., 2020). However, the amount of resources is limited compared to the NLP resources that can help to develop powerful image-based predictive models (Imran et al., 2020). One of the main reasons of less progress in image-based solutions for disaster analysis is the lack of annotated benchmark datasets. To overcome this limitation, several interesting image datasets have been collected for different applications. Some prominent datasets for disaster imagery content analysis include damage assessment dataset (Nguyen et al., 2017b), crisis multimodal dataset (CrisisMMD) (Alam et al., 2018a), crisis incident dataset (Weber et al., 2020), crisis image benchmark dataset (Alam et al., 2020), and MEDIC (Alam et al., 2022). Moreover, to promote the research in the domain, several shared tasks have also been organized in the past years as detailed in section “[Shared Tasks](#).”

Despite being less explored, compared to textual information, social media imagery has been used for several critical applications to respond to disasters by developing information/task-specific classification models. These include several classification tasks such as (i) disaster types, (ii) informativeness, (iii) humanitarian, and (iv) damage severity assessment (Alam et al., 2021). Other important and relevant classification tasks include sentiment analysis from disaster-specific social media images (Hassan et al., 2019), road passability (Bischke et al., 2017b), and identification of flooded regions (Bischke et al., 2017a). The literature reports that to monitor real-time disaster events and extract information that are related to humanitarian responses, such types of classification models are needed (Alam et al., 2017, 2018b).

Even though studies suggest that the information posted on social media can help increase situational awareness, inform rescue operations, and save lives (Enenkel et al., 2018), the utility of such information has not been widely used. For example, Villegas et al. (2018) reported that during Hurricane Harvey, the FEMA (<https://www.fema.gov/>) missed 46% of the critical information posted by affected people on Twitter and CrowdSource Rescue (<https://crowdsourcerescue.com/>) volunteers, and thus, many areas heavily impacted by the hurricane were missed from the original damage estimates provided by FEMA. Authors highlighted that Twitter and crowdsourced sites can be used to make response and recovery more robust during disasters, which FEMA has missed.

To facilitate such stakeholders during disaster response, there have been efforts to develop real-time systems to crawl, index, and categorize social media content in real time (Alam et al., 2018b). However, such efforts are still limited and require more attention to deal with large-scale social media data that can benefit the first responders in their operational decision-making process. This book chapter

discusses the applications, challenges, and potential of social media imagery in disaster informatics. In detail, it provides an overview of the research effort for social media imagery content analysis. Specifically, a detailed report of the publicly available datasets, methodologies proposed in different studies, and systems built to facilitate first responders is provided. The chapter also highlights possible use cases (i.e., applications), shared tasks that create a scientific community and advance the field. Finally, an overview of current challenges and future research opportunities is provided.

Related Work

Over the last decade, social media emerged as an instant source of communication and information and a widely accessible forum for discussion on societal and environmental challenges (Said et al., 2019). The literature already reports several interesting applications of information shared in social media platforms in coping with societal and environmental challenges, such as water and air quality analysis (Ahmad et al., 2022; Zheng et al., 2019). Social media platforms are also widely explored for natural disaster detection, aftermath analysis, and its impact on the environment and infrastructure (Said et al., 2019). Its ability to engage a large volume of the audience makes social media a preferred choice for communication, information dissemination, and several other interesting and critical tasks in disasters and emergency situations. Depending on the nature of social media platforms, useful information is generally available in different forms including textual, visual, and geo-location information. The geo-location information helps in obtaining localized and relevant textual and visual information for different applications of disaster informatics. The literature already indicates the potential of both textual and visual information in different applications of natural disaster-related social media content. However, the scope of the chapter is limited to visual content only, and it covers the literature based on the utility of social media imagery in natural disasters only.

Thanks to the recent development in artificial intelligence (AI)-based systems and computational technologies, useful insights and actionable information can be extracted from disaster-related social media imagery (Nguyen et al., 2017b). For instance, several efforts have been made to automatically analyze flood-related social media imagery for the identification of passable routes in a flooded region (Bischke et al., 2019). Other relevant studies include monitoring the rehabilitation activities after natural disasters and estimating flood level in social media imagery (Chaudhary et al., 2019). More recently, disaster-related social media imagery is analyzed to extract and perceive observer's (i.e., social media users) sentiments and emotions for different stakeholders, such as news agencies and humanitarian organizations (Hassan et al., 2020). Some other key applications of disaster-related social media imagery include news disambiguation, quantification of a disaster event, and information gathering and dissemination.

A vast majority of the literature focus on flood events, in which flood-related imagery is analyzed for a diversified set of applications. The tendency toward floods

is mainly due to their higher occurring frequency compared to other types of disasters, such as wildfires, earthquakes, landslides, and floods. Moreover, data on flood events is easily available compared to some rare events, such as landslides. Flood event detection and analysis in social media imagery have also been part of several benchmark competitions as detailed in section “[Challenges and Open Research Issues](#).” The literature also reports some interesting works on other types of natural disasters. For instance, Ahmad et al. (2018) collected and analyzed social media imagery related to seven different types of natural disasters including floods, earthquakes, landslides, wildfires, cyclones, thunderstorms, and snowstorms. However, very few attempts have been made for analyzing social media imagery for these types of natural disaster events. The literature still lacks a large-scale dataset covering social media imagery from several types of natural disasters that could be used for training and evaluation of AI-based systems for different relevant tasks. This chapter discusses such challenges to research community in exploring the full potential of social media imagery in disaster analysis.

Resources, Models, and Systems

Datasets

This section provides an overview of some of the publicly available social media imagery datasets reported in the current state of the art (Table 1).

MediaEval 2017 dataset (Bischke et al., 2017b). The MediaEval 2017 shared task introduced two datasets to address two different tasks namely (i) disaster image retrieval from social media and (ii) floods detection in satellite imagery. The images for the first subtask are collected from the YFCC100M dataset using the keywords including *flooding*, *flood*, and *floods*. The curated dataset consists of 6,600 images. The label (*yes* vs. *no*) for each image is defined based on the evidence of a flooding event. The dataset is released in two different sets: (i) development set and (ii) test set. The development set contains 5,280 images, and the test set contains 1,320 images. The dataset for the second subtask consists of satellite image patches derived from Planet’s 4-band satellites.

Damage assessment dataset (DAD) (Nguyen et al., 2017b). This dataset consists of ~25 K images labeled with damage severity levels, which include *severe*, *mild*, and *little to no damage*. The images have been collected from two different sources: (i) Twitter (Tweets are collected during four natural disasters using AIDR tool (Imran et al., 2014). The disaster events include Typhoon Ruby in 2014, Nepal Earthquake in 2015, Ecuador Earthquake in 2016, and Hurricane Matthew in 2016.) and (ii) Google. The data collection process required to crawl data from Google. In order to do so, authors used the following keywords: *damage building*, *damage bridge*, and *damage road*. The collected images have been manually annotated using Figure Eight crowdsourcing platform (<https://appen.com/figure-eight-is-now-appen/>).

Table 1 summarizes key features of the datasets

MediaEval 2018 dataset (Benjamin et al., 2018). The MediaEval 2018 shared task released two datasets for two different subtasks, namely, (i) flood classification from social multimedia and (ii) flood detection from satellite imagery. The dataset for the first task is composed of more than 10,000 tweets with associated images. The dataset is provided in two different sets. The development set consists of 7,387 tweets with accompanying images, while the test set is composed of 3,683 tweets and images. The tweets have been collected using the keywords *flooding*, *flood*, and *floods* during the three major hurricane events (i.e., Harvey, Irma, and Maria) back in 2017. The annotation consists of two hierarchical labels: (i) evidence of road passability based on the image of the tweet (0 = no evidence vs. 1 = evidence) and (ii) based on the decision (i.e., showing evidence of passability) of the first label; another label is introduced for actual road passability (0 = not passable vs. 1 = passable).

The dataset for the second subtask consists of 1,664 satellite image patches (with a spatial resolution of 512 x 512 pixels). The image patches were extracted from DigitalGlobe’s WorldView satellite (<http://worldview3.digitalglobe.com/>). The image patches have a ground-sample distance of about 0.5 m and were collected during Hurricane Harvey in 2017 from the Houston area. The label for the image patches is *flooded* vs. *unflooded*. Image patches also have two additional binary labels: *yes* and *no* for the road passability between the two given points/locations. It consists of 1,438 and 226 image patches for the development and test sets, respectively.

CrisisMMD (Alam et al., 2018a). It is a multimodal (i.e., containing tweet’s text and image) dataset, which consists of 18,082 images collected from Twitter during 7 different natural disaster events, using the AIDR system. The annotation targeted multiple tasks including (i) informativeness with binary labels, *informative* and *not informative*, (ii) humanitarian categories with seven class labels, and (iii) damage severity with three labels.

Damage multimodal dataset (DMD) (Mouzannar et al., 2018). This is another multimodal dataset, in which images are collected from Instagram and Google. The authors crawled the images using more than 100 hashtags, which are based in the crisis lexicon (Olteanu et al., 2014). The manually annotated dataset consists of 5,878 images with 60 class labels. The *non-damage* images include irrelevant information, such as cartoons, advertisements, and information that is not relevant or useful for humanitarian tasks.

VisSenti (Hassan et al., 2020). This dataset consists of 4,003 disaster-related images labeled with 4 different sets of labels. The first set of labels consists of three sentiment polarity labels such as *positive*, *negative*, and *neutral*. The second set of labels consists of *relax/calm*, *normal*, and *stimulated/excited*. The third set, which aims at multiclass multi-label image classification, of labels consists of seven emotion categories including *joy*, *sadness*, *fear*, *disgust*, *anger*, *surprise*, and *neutral*. The final set consists of more fine-grained emotional episodes, such as *anger*, *anxiety*, *craving*, *empathetic pain*, *fear*, *horror*, *joy*, *relief*, *sadness*, and *surprise*. The images are crawled from Twitter, Flickr, and Google using relevant keywords, such as *floods*, *hurricanes*, *wildfires*, *droughts*, *landslides*, and *earthquakes*.

Crisis image benchmark dataset (Alam et al., 2020). The images in this dataset are collected from Twitter, Google, Bing, Flickr, and Instagram. A large portion of the images have been collected from Twitter, which were mainly collected during major natural disaster events. Similarly, relevant keywords are used to collect images from Google, Bing, Flickr, and Instagram. The dataset has diverse characteristics in terms of (i) number of events (more than 15 events), (ii) different time frames covering 4 years, (iii) natural vs. man-made disasters, and (iv) events that occurred in different parts of the world.

Incident dataset (Weber et al., 2022). The incident image dataset consists of manually annotated images with 43 different incidents across a variety of scenes. The annotation has been done in a multi-label setting. The dataset has been released in two phases and the last release consists of 1 M images.

MEDIC (Alam et al., 2022). The MEDIC dataset is the largest social media image dataset for humanitarian response task. It consists of 71,198 images that are associated with 4 different tasks annotated and designed for multitask learning. These tasks include (i) disaster type (seven labels), (ii) informativeness (binary labels), (iii) humanitarian (four labels), and (iv) damage severity (three labels).

Models and Systems

This section provides a brief overview of publicly available tools, systems, and methods that have been proposed in the current literature.

Models

Most of the early efforts in the domain aim at classical approaches. In these methods, generally, handcrafted features, such as SIFT, SURF, ColorSURF, ColorSIFT, and Bag of Words (BoW), are used for image representation. Then, classical algorithms, such as support vector machine (SVM), are used for classification purposes. However, the later approaches mostly rely on deep learning (DL) models. The DL models are used in different ways including transfer learning (i.e., fine-tuning the pretrained CNN models for domain-specific tasks), retraining, and using the models as feature extractors (Ahmad & Conci, 2019).

The literature reports better performances for the DL-based solutions compared to the classical approaches. For instance, Nguyen et al. (2017b) compared BoW (i.e., classical approach) and transfer learning approaches (i.e., DL-based solution) and demonstrated that the domain-specific fine-tuning outperforms BoW-based techniques. Given that DL solutions in general and transfer learning, in particular, have shown promising results for various image classification tasks, currently, it has been widely used in the literature (Said et al., 2019). In disaster informatics, two different types of pretrained models are mostly exploited: (i) pretrained on the ImageNet dataset (Deng et al., 2009) and (ii) pretrained on the Places dataset (Zhou et al., 2017). The models pretrained on ImageNet extract object-level information, while the models pretrained on the Places dataset extract scene-level features. A diverse set of CNN architectures pretrained on these datasets have been used

in the domain. Most notable ones include VGG16 (Simonyan & Zisserman, 2014), ResNet18, ResNet50, and ResNet101 (He et al., 2016). Moreover, the object detection-based approach has also been used in several studies. For example, Asif et al. (2021) used YOLO to analyze disaster-related images and detect disaster types. Despite being very effective in different tasks, several limitations of CNNs have been in the literature. For instance, the max-pooling operation results in the loss of critical information about the location and frequency of relevant features. To address such limitations, a capsule network-based approach has been proposed in the literature (Sabour et al., 2017). There are also several works relying on the fusion of multiple DL models, such as the solutions presented in (Ahmad et al., 2017c).

Table 2 reports the most recent studies – presenting dataset, task addressed, models used, and their performances. Overall, across the tasks, the models' performances are above 60% with a maximum of 99%. The performances of the solutions depend on the complexity of the applications and the nature of the problem (i.e., binary vs. multiclass classification settings).

Systems

Some of the research efforts in the domain also resulted in the development of systems/tools that are deployed in real-world applications. For instance, recently Alam et al. (2018b) developed a crisis-related social media image processing system/tool. The tool provides a complete pipeline including all the essential components ranging from image collection, removing duplicates and irrelevant images, and finally classifying them on the basis of damage severity. The system has been deployed in many real-world disaster events. A recent example is the deployment of the system during Hurricane Dorian as reported in (Imran et al., 2022). The system has deployed for 13 days, and it collected ~280 K images. The crawled images are then classified using the models proposed in (Ofli et al., 2020). The classified images are then used by a volunteer response organization (MCCERT:<https://montgomerycert.org/>). Another system is proposed for the detection of disaster-related damage in the cultural heritage sites (Kumar et al., 2020). Very recently, a similar system has been proposed for landslide image detection, which monitors social media platforms and detects landslide images (Ofli et al., 2021). Ahmad et al. (2017b) developed a system, namely, JORD for the detection of natural disasters in social media and satellite imagery. The system is able to automatically retrieve a list of the recent disaster from the EMD dataset and starts collecting relevant imagery from several social media outlets and satellites (Google Earth).

Applications

This section provides an overview of some of the already explored key applications of natural disaster-related social media imagery. These applications include the following:

Table 2 A summary of the state-of-the-art models for disaster analysis in social media contents

- **Disaster event detection and information dissemination:** In the modern world, social media has emerged as an important channel for communication and information dissemination, especially in emergencies. The literature reports the effectiveness of social media outlets in several situations where the conventional sources and news agencies failed to provide relevant information about natural and man-made disasters in time or at all due to several reasons, such as lack of reporters in the area (Said et al., 2019).
- **Flood severity estimation:** Natural disaster-related social media imagery could also be used for the estimation of disaster severity. In this regard, in the literature, flood-related images are mostly used to estimate flood level. To this aim, different strategies are used. For instance, in a recent benchmark challenge, participants were asked to develop binary classification frameworks able to predict whether the water level is above the knee of a person standing in floods. Despite some initial successful attempts, flood-level estimation from social media imagery, which is generally captured through RGB cameras, is very challenging. The complexity of the application is also apparent from the lower performances of the solutions proposed for the task in a benchmark competition (Bischke et al., 2019). However, there is a big potential in the application, and the performance of the solutions could be improved by incorporating complementing sources of information, such as IR imagery, metadata, and crowdsourced data.
- **News disambiguation:** Natural disaster-related social media imagery could also be used for the verification of disaster event-related news articles' content. Some irrelevant news articles may also contain disaster-related keywords, such as "floods of flowers." In such circumstances, the images associated with news articles can be used to identify whether the articles are representing a disaster event or not. The literature already reports some efforts in this direction. For instance, Ahmad et al. (2019b) proposed a fusion-based framework for differentiating relevant and nonrelevant articles based on the associated images.
- **Identification and classification of needs of affected individuals:** The identification and categorization of the needs of affected people are of great interest to humanitarian organizations. This information helps them to deploy their resources accordingly. The literature also reports some efforts in this direction. For instance, Alam et al. (2020) explored the possibility of automatically identifying four different categories of images, which include (i) affected people, (ii) infrastructure and utility damages, (iii) rescue volunteering or donation effort, and (iv) not humanitarian (images showing cartoon, advertisements, etc.).
- **Monitoring and facilitating rescue and reconstruction operations:** Social media imagery could also be used for monitoring the rehabilitation process and rescue operations. Though very few attempts have been made, there is a lot of potential in this application. Such monitoring schemes and analyses could be used for different purposes. For instance, Yan et al. (2017) used geotagged social media data for monitoring and assessing post-disaster tourism recovery. Moreover, social media imagery could also be used to encourage people for the donation.

- **Quantification of disasters' impact on the infrastructure:** The application was recently introduced in a benchmark competition and aims at analyzing floods' impact on infrastructure. The challenge in the competition was limited to road passability, where participants were asked to predict whether a road in a flooded region is passable with common means of transport or not. However, the application can be extended to several other tasks, such as monitoring communication cables, gas pipelines, electricity, and water networks after different types of natural disaster events, such as floods, earthquakes, snowstorms, landslides, and wildfires (Bischke et al., 2017b).
- **Visual sentiment analysis:** Sentiment analysis of disaster-related social media images is a relatively new and less explored area. The application is recently introduced by Hassan et al. (2019) by providing a detailed overview of the problem, applications, potential stakeholders, opportunities, and associated challenges. The potential beneficiaries of the application include news agencies, humanitarian organizations, and the general public. For instance, it can help news agencies to collect disaster-related information from different perspectives (Hassan et al., 2020). Similarly, it can also help humanitarian organizations to disseminate information on a wider scale by providing images that best demonstrates the evidence of a disaster. However, several challenges are associated with the application. For instance, disaster-related imagery generally contains several objects and background information and is hard to analyze and extract emotions and sentiments. Moreover, in such complex and subjective applications, defining the sentiment categories and annotation of images is also a tedious job.

Shared Tasks

Disaster analysis in social media content has also been part of several benchmark initiatives. In this regard, MediaEval (<http://www.multimediaeval.org/>), which is a benchmarking initiative offering challenges in the form of shared tasks, is leading by offering the task for the last 5 years. In the benchmark competition, each year a different application is explored. A brief overview of some of the shared tasks aiming at disasters analysis in social media imagery is provided below.

- **The multimedia satellite task at MediaEval 2017** (Bischke et al., 2017b): The goal of the task is to categorize flood-related images that are collected from social media and satellite. To this aim, two different subtasks including (i) disaster image retrieval from social media (DIRSM) and (ii) flood detection in satellite imagery (FDSI) were introduced. The first task aims to analyze and retrieve flood-related images collected from social media, while the second task focuses on images collected from the satellite. The second task is out of the scope of the chapter, and we will cover the details of the first task only. For DIRSM, a total of 11 teams participated. The participants were allowed to submit a total of five different runs, which were evaluated in terms of precision at different cutoffs, $k = 50, 100, 200, 300, 400$, and 500. The majority of the proposed solutions were based on CNNs, where mostly existing pretrained models were fine-tuned on the

dataset provided for experiments. Several interesting early and late fusion strategies were also employed. Overall encouraging results were reported on the task.

- **Emergency response for flooding events at MediaEval 2018** (Benjamin et al., 2018): The main goal of this task is to analyze and identify the impact of floods on the infrastructure. Similar to the previous year, the task is divided into two subtasks, namely, (i) flood classification from social multimedia (FCSM) and (ii) flood detection from satellite imagery (FDSI). The first task, which is relevant to the chapter, aims to analyze and retrieve social media images providing direct evidence for road passability through conventional means of transport, such as cars (i.e., “no boats, off-the-road vehicles, farm equipment, etc.”) (Benjamin et al., 2018). To this aim, the participants were asked to propose image classification frameworks able to differentiate images of possible and non-passable roads. A total of nine teams participated in the task, where each team was allowed to submit up to five different runs/solutions. Moreover, the proposed solutions were evaluated in terms of average F1-score.
- **Multimedia satellite task flood severity estimation at MediaEval 2019** (Bischke et al., 2019): The main goal of the task is the estimation of flood severity in social media and satellite images. The task is mainly composed of three subtasks. Two of the subtasks are based on social media, while one of the tasks aims at analyzing satellite imagery. In the social media-related subtasks, two different applications, namely, (i) image-based news topic disambiguation and (ii) multimodal flood-level estimation, are covered. In the first subtask, the participants were asked to propose binary classification frameworks able to predict whether an image associated with an article represents flood events or not. In the second task, the participants were asked for further analysis of flood-related images by identifying the images containing *at least one person standing in water above the knee*. In total, 12 teams participated in the task. The participants were allowed to submit up to five different runs/solutions, which were evaluated in terms of F1-score. Overall, lower performance was observed on each task.
- **The flood-related multimedia task at MediaEval 2020** (Andreadis et al., 2020): This task aims at the identification/detection of flood events in a particular area in ambiguous Twitter posts. The participants were provided with a large collection of flood-related tweets along with the associated images and were asked to develop a multimodal classifier able to predict whether the tweets represent flooding events in a specific area (i.e., the Eastern Alps district in Northeastern (NE) Italy) or not. In total, five teams participated in the task, and similar to the previous editions, each team was allowed to submit up to five different runs/solutions. Similar to previous editions, the majority of the teams proposed late fusion-based multimodal frameworks combining classification scores obtained with the models trained on textual, visual, and metadata. Overall poor performances, in terms of F1-scores, were reported for all the teams, which indicates the complexity of the task.
- **Visual sentiment analysis – a natural disaster use case at MediaEval 2021** (Hassan et al., 2021): This task explores a completely different and interesting

aspect of natural disaster analysis in social media. The task aims at sentiment analysis of disaster-related images posted on social media. The task consists of three different subtasks, which include one single and two multi-label image classification tasks. In the first subtask, the participants were asked to differentiate between three different categories of emotions, *positive*, *negative*, and *neutral*. In the second subtask, the participants had proposed a multi-label image classification framework to differentiate among seven classes, such as *joy*, *sadness*, *fear*, *disgust*, *anger*, *surprise*, and *neutral*. The third subtask consists of ten classes including *anger*, *anxiety*, *craving*, *empathetic pain*, *fear*, *horror*, *joy*, *relief*, *sadness*, and *surprise*. A total of five teams participated in the task. Similar to previous tasks, the majority of the proposed solutions was based on pretrained models, which were fine-tuned on the new dataset. Overall, better results were reported on all three subtasks (Table 3).

Table 3 Provides a summary of the shared tasks on the topic in terms of the number of teams that participated, evaluation metrics, and the score of the best-performing team

References	Year	#T	Metrics	Top system	Top score	Task overview
Bischke et al., 2017b	2017	11	Precision at $k = 50, 100, 200, 300, 400, 500$	Ahmad et al., 2017c	0.957	Aims at retrieval of flood-related images from social media by covering two classes relevant and nonrelevant. Also provides access to metadata associated with the images
Benjamin et al., 2018	2018	9	Avg. F1-score	Moumtzidou et al., 2018	0.665	Aims to analyze and quantify the impact of floods on the infrastructure by proposing solutions for road passability through conventional means of transport
Bischke et al., 2019	2019	12	F1-score	Quan et al., 2019	0.883	Aims at flood severity estimation by introducing two subtasks relevant to social media where two different applications, namely, image-based news disambiguation and flood-level estimation, are introduced

Challenges and Open Research Issues

This section highlights some of the key challenges and open research issues in the domain. These challenges include the following:

- **Data collection and annotation:** Data collection and annotation are the key challenges to develop models and extracting actionable information from disaster-related imagery for different tasks. Although several interesting datasets aiming at different applications have been collected and shared. However, there remains many problem settings where new dataset needs to develop. In addition, each application of natural disaster-related imagery analysis requires its own annotated dataset, and the challenges associated with data annotation vary from application to application. For instance, the annotation of data for certain applications, such as sentiment analysis of disaster-related images, is more challenging to compare to others (Hassan et al., 2021).
- **Relevance and authenticity:** Despite being proven effective in a diverse set of applications, the relevance and authenticity of social media content are very challenging. To retrieve relevant social media imagery, the majority of the solutions relies on state-of-the-art AI, ML, and image processing techniques to automatically analyze natural disaster-related imagery shared in social media platforms. However, the existing literature lacks frameworks and solutions dealing with the authenticity of natural disaster-related imagery shared in social media (Said et al., 2019). We believe that additional measures (such as disinformation detection), ensuring that the retrieved imagery is authentic and genuine, need to be incorporated in the analysis of disaster-related social media images.
- **Copyrights issues:** The social media data may also be subject to copyrights. Under such circumstances, it is not possible to use and share the data with the community for training and evaluation. In fact, it is important to make sure the social media imagery is licensed for public use. This restriction poses challenges to the collection and sharing of benchmark datasets in the domain.
- **Missing geo-location information:** To fully explore the potential of natural disaster analysis by extracting actionable information, geo-location information is crucial in several ways. For instance, geo-location information along with other information extracted from imagery can help rescue teams and aid agencies to deploy their resources accordingly. However, the literature suggests that social media imagery generally lacks geo-location information due to several reasons (Ahmad & Conci, 2019). In this regard, some image localization solutions could be employed to deal with missing geo-location information.

Conclusions

This chapter discusses how social media imagery content has been used during disasters for actionable information with a particular focus on the challenges, available datasets to develop AI-based models, and already deployed systems. It

also highlights possible applications/use cases that can be deployed during such disaster events and how such applications can facilitate different stakeholders, crisis responders, or emergency response teams. There are already sincere efforts for finding suitable solutions to deal with the large amount of social media content, which resulted in several shared tasks on the topic in the past few years. However, there are still several challenges that need to be tackled to explore the full potential of social media imagery in disaster informatics.

Abstract

The utilization of remote sensing tools gained a relevant role in the assessment of impact of natural and human-made disasters. These tools tend to integrate field primary data collection with the availability of timely big data. Data analysis from satellite images can be utilized to design a sample strategy when no up-to-date census data are available or to identify and prioritize disaster-affected communities and their respective assets. Remote sensing products can also provide new information around socioeconomic indicators to either corroborate the existing primary data or generate new knowledge in the phases of relief, reconstruction, and recovery.

Remote sensing · Satellite images · Vulnerable population · Natural disaster · Crisis

Introduction

In the aftermath of a disaster, to make crucial decisions on effective response and recovery, policymakers and international organizations need information that is rapidly available, accurate with a preference for georeferenced, and, to the extent possible, granular and hyper-localized. Optimally, this information should come from primary data collection in the location where the disaster occurred. Unfortunately, oftentimes, such locations are not easy to reach in a short period of time in the aftermath of the disaster due to logistics constraints, an ongoing conflict, or political instability. Big data from non-traditional sources such as social media images, text analysis, or satellite images can rapidly provide actualized and localized data to integrate official statistics (Vacarelu, 2016). Multiples are the advancement in collecting and analyzing big data to provide a prompt intervention. Remote sensing combined with telecommunication call records, processed by machine learning, has been used successfully to deploy a mobile cash distribution in Togo (Marchenko & Chia, 2021) in support of families living in extreme poverty and impacted by COVID-19. The triangulation of data coming from multiple sources is a critical success factor in tackling vulnerability. By analyzing power electricity network distribution, the use of big and thick data and a combination of the two in Ukraine helped in unpacking vulnerability complexities and finding new policy options and solutions to tackle the rising inequalities, new forms of poverty, and social exclusion, among others (Vasilescu et al., 2021). Big data is used on a regular basis by the Crisis Bureau at UNDP for early warning and horizon scanning for the fragile crisis. The CRD (Crisis Risk Dashboard) helps UNDP anticipate and respond to risks at global, regional, and country levels by providing easy access to timely and relevant data visualizations and analysis, but, most of all, by telling clear and compelling data stories and effectively communicating key trends and risks (Corrado Scognamillo & Gutschke, 2021). Finally, the work for disaster detection and analysis in the UN system is empowered by UNOSAT. A collaboration between UNITAR-UNOSAT and UN Global Pulse has developed a methodology that allows to quickly map flooded areas using artificial intelligence (AI) and remote sensing (Nemni et al., 2020). Its application makes it possible to better geo-sampling for in-depth primary data collection and organize logistics and ground-truthing validation processes with data in the aftermath of disasters affecting large areas. As time is crucial in crisis response, automating damage detection and mapping plays a fundamental role in informing the decision-making process to help optimize the disaster response, and it also has the potential to significantly reduce loss of life and mitigate structural damage. The Surge Data Hub (SDH, n.d.-a, b) collects mainly primary data through field assessments. The data collected

validate and serve back to train algorithms for automated damage assessments. Through the Household and Building Damage Assessment (HBDA) and Socio-Economic Impact Assessment (SEIA), it is possible to assess damages to buildings or infrastructure, and household needs, and to map vulnerability at a multi-dimensional level. In the aftermath of natural or manmade disasters, assessing both building and infrastructure impact along with economic and livelihood assets and household needs and vulnerabilities, at a granular level, gives a more comprehensive picture of a shock impact. Because of their timely availability and limited cost, remote sensing tools have become a convenient way to collect information. In the various phases of disaster management, i.e., prevention, preparedness, relief, and reconstruction, remote sensing data are utilized (Van Westen, 2000). Remote sensing tools have become increasingly important for disaster management due to their cost-effectiveness, short temporal orbiting, and large areas of coverage. First, remote sensing and GIS can help to determine which areas are in danger. Second, remote sensing allows monitoring the event during its occurrence and organizing emergency operations accordingly. Then, it can provide a quantitative base for relief operations in damage assessment and aftermath monitoring. Finally, it assists in the organization of the damage-related information and the post-disaster census information and the evaluation of sites for reconstruction.

This chapter focuses on remote sensing tools and provides an overview of their applications in crisis response and disaster assessment. Remote sensing tools constitute a fundamental resource in crisis and disaster assessments. Read and Torrado (2009) define remote sensing as follows: “*it provides information about objects at or near the surface of the Earth and atmosphere based on radiation reflected or emitted from those objects. The information is usually captured at a distance from above in the form of image data. Such data allow us to determine the composition and nature of the Earth’s surface and atmosphere from local to global scales and assess changes by analyzing images captured at different points in time. In this sense, remote sensing is useful in providing spatial information that is otherwise difficult or impossible to obtain. In the social sciences, remote sensing is useful for visualizing (providing alternative and synoptic views) and classifying human environments.*” Here are the lessons learned by combining theoretical knowledge and hands-on experience in the application of remote sensing in disaster and risk reduction. Data obtained from the elaboration of satellite images, such as flooded land and damaged buildings, increase the level of precision of an intervention. While planning data collection in the field, high-definition data on population and building distribution support more efficient sampling strategies. Moreover, remote sensing data can provide insightful information on socioeconomic outcomes beneficial to assessing the potentially vulnerable population.

The following sections explain how remote sensing tools integrate with the UNDP crisis response framework. The first section exposes how organizations like UNDP have been adopting UNOSAT data, like in the case of the Bata explosion and the Timor-Leste flood. The second section, in the case of Guatemala, explains how high-definition population distribution data can support the design of a survey when

up-to-date or localized data are not available. The third section elaborates on how remote sensing tools can support the calculation of more traditional measures of vulnerability, namely, the multidimensional vulnerability index (MVI). The fourth section discusses the use of nightlight satellite images to measure the economic impact of a crisis, like in the case of Afghanistan, where the research opens great opportunities to use the same methodology for more disaster-related cases. Finally, the chapter concludes and opens the discussion to further developments and ways forward.

Conceptual Framework for the Use of Remote Sensing in Crisis Response

The complexity of crises requires coordinated action to assess their impact and put in place adequate recovery policies. UNDP has recently developed a conceptual framework that use remote sensing tools to better address this issue. This framework consists mainly of three phases:

Phase 1: It is triggered as soon as a natural disaster occurs and consists in using UNOSAT satellite imagery to have a first information on the areas affected by the disaster and an approximation of the number of affected houses.

Phase 2: It is divided into two parts. The first part involves the use of remote sensing in the traditional primary data collection to assess the impact of the disaster on buildings and households. This is done by using the satellite data produced by UNOSAT or population data generated from satellite data to conduct a “spatial sampling,” which consists of selecting the households and buildings to be surveyed to ensure that the data are representative. Primary data collected through spatial sampling leads to the calculation of a multidimensional vulnerability index to identify the most vulnerable groups and the dimensions on which they are most affected. Although this traditional methodology presents several advantages, it can be difficult to implement especially when the affected areas are not accessible. Therefore, the second part consists of using new approaches with remote sensing to assess the impact of disasters. In this case, satellite imagery on nighttime electricity and population density is used to assess the impact of disasters on economic activity. Depending on the context, both methodologies can work either as substitutes or as complements.

Phase 3: This phase consists of a synthesis of phase 2, drawing out the information needed to develop recovery policy. Thus the areas where economic activity has been most affected by the disaster can be determined, and the groups that have been most vulnerable to the crisis can be identified. This allows for prioritization in the overall post-crisis recovery strategy.

Each of the following sub-sections addresses remote sensing tools’ role in the conceptual framework phases and will present an example of its application in the context of various recent crises.

UNOSAT Satellite Image Processing Services

In the aftermath of natural disasters, time and resources to collect reliable data to inform decision-making are scarce. Conducting a full-scale *in situ* assessment to identify the impact on households and damages can be dangerous or just not feasible; remotely sensed secondary and/or primary data can be used to identify those areas that are affected by the natural disaster or other sorts of human-made crisis. Even when primary data collection is conducted at the field level, e.g., household surveys, many are the benefits from remote sensing data, such as to prioritize areas to be assessed and guide field assessment teams.

UNITAR's Operational Satellite Applications Programme (UNOSAT) rapid mapping service provides satellite images, maps, georeferenced data (e.g., flood extents, damage assessments), statistics, and reports. It is activated in the case of floods, earthquakes, storms, landslides, volcanoes, oil spills, chemical waste, refugee and internally displaced person (IDP) camp mapping, conflict damage assessment, and situation analysis. The flood rapid mapping tool is a machine learning-based tool developed by UNOSAT. Data are derived by UNOSAT analysts from various satellite images acquired by multiple sensors. UNOSAT analysts then extracted water bodies and inundated lands from these images using a hybrid unsupervised and supervised classification followed by visual review and manual correction. This almost fully automated process permits to complete satellite-based analyses and related mapping in rapid times.

UNOSAT data can be employed to facilitate data collection after a natural or manmade disaster occurs, for example, the Bata explosion, in Equatorial Guinea, where a series of six explosions created severe damage to households and infrastructure in a 3-km radius affecting 1900 buildings. By using as a first layer the UNOSAT geospatial analysis, the damages in private buildings and households' needs were assessed, giving detailed evidence, cost estimation for damage recovery, and community resilience. Another case is represented by the Timor-Leste flood in April 2021 (UNDP, 2021) where the heavy rains that followed Tropical Cyclone Seroja afflicted Timor-Leste from March 29, 2021, to April 4, 2021. The state of calamity was declared by the government on April 8, 2021, in Dili for a period of 30 days, and international assistance was requested. Even in this case, UNOSAT data were employed to identify the geographic scope of the Housing and Building Damage Assessment (HBDA).

The geographical scope concerns the five worst impacted municipalities in Timor-Leste, i.e., the municipality of Dili, which includes the capital city, Liquica, Manatuto, Baucau, and Ainaro. Different methodologies were applied for Dili municipality and for the other four municipalities' area, because of the varied nature of available baseline and secondary data, as well as limited resources and information needs on the populations of interest. The most affected areas in the municipality of Dili were identified using maps of satellite-derived imagery from UNOSAT, which pinpointed potentially affected structures (purposive sampling) as shown in Fig. 1. Subsequently, a random sample was then generated within each of these affected areas to identify individual buildings to be assessed, using the GPS

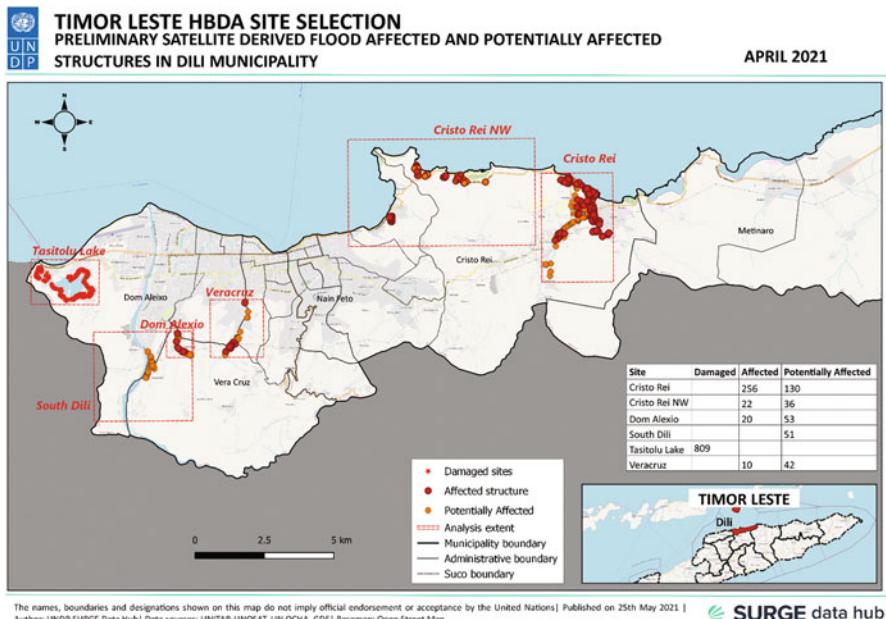

Fig. 1 Timor-Leste HBDA site selection

coordinates from UNOSAT's data. The size of the sample was calculated by applying a 95% level of confidence and 5% margin of error, using the number of structures identified by UNOSAT in each "affected area."

In the four municipalities outside of Dili (i.e., Liquica, Manatuto, Baucau, and Ainaro), potentially affected areas were identified using data on the estimated number of affected buildings and households based on the multi-sector rapid assessment by the Secretary of State for Civil Protection. Therefore, only a purposive sampling method was employed. Field teams traveled to the identified areas and then selected households for assessments in close cooperation with the local authorities, including municipal authorities, village and sub-village chiefs, and municipality statistics office staff. Contrary to the municipality of Dili, sample units (buildings/households to survey) were identified while in the field rather than prior.

Consequently, representative data was collected in the most affected areas within Dili municipality, while indicative data was collected in the four municipalities outside Dili. A summary of the data collected in this assessment can be observed in Fig. 2. This exercise emphasizes the need to adapt sampling strategies under available information, which may come in differing formats and data types. Nonetheless, the availability of UNOSAT processed satellite images allowed for a more representative analysis and a cost-effective approach.

In future studies, a few considerations in the use of these data and methodologies should be taken. First, UNOSAT damaged buildings are obtained from the observation of satellite images, and despite being often the most accurate data available, they

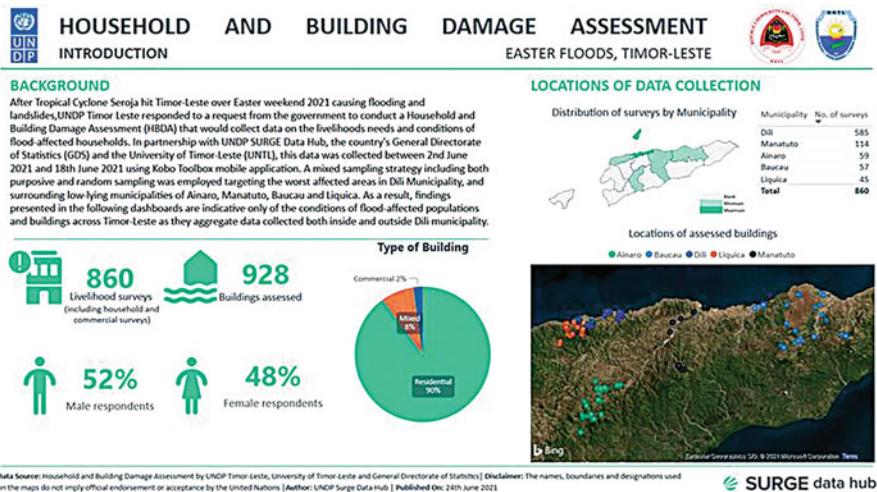

Fig. 2 Timor-Leste HBDA

may be subject to measurement error. The assessment of the level of damage is extrapolated from a view of the building roof, and this information may be not completely revelatory of the damage magnitude as it would be observing the building in the third dimension. For such reason, it is relevant that future studies could utilize UNOSAT data on damaged buildings as a benchmark to identify the affected areas to assess but also to combine them with other methods to increase our knowledge of this potential measurement error.

Spatial Sampling

Many low- and middle-income countries – especially those that are most in need of household surveys to guide data-driven decision-making in a crisis situation – lack precise and up-to-date information about their population impacted by a disaster. Some crises trigger population movements that add to seasonal patterns of internal or inter-country migration that make even more arguable the use of sample frames based on earlier population data. The standard approach to overcome this problem is to use a two-stage sampling design in which primary sample units (PSU) are selected with probability proportional to the population size estimated from the census and then a listing and a random sampling are conducted in the selected primary sampling units. A critique of this methodology is that the most vulnerable population is most likely to be left out of the survey. For example, the low-income population is the one growing faster and therefore may be underestimated by using the census and mobile population. For example, pastoral communities and refugees can be undercounted or signed as not respondents in between the listing phase and the interview phase. Furthermore, the SDGs are emphasizing the need for more disaggregated estimators,

especially in small areas, and census data may not have this geographical precision in a specific timeframe.

The most common approach to address representability in large-scale household surveys is to use a stratified two-stage design. In the first stage, census enumeration areas are set as the primary sampling unit (PSU) and selected with probability proportional to population size. In the second stage, a household listing operation is performed in the chosen PSUs, and households are selected using a simple random sampling. This approach allows using even outdated census data in the first stage, as long as a high-quality listing operation is done in the second stage to select the households to survey. Using out-of-date census data as a measure of size in PSU selection will result in estimates that are inefficient but still unbiased (Eckman & Himelein, 2020). Although this method is considered to be the best from a statistical point of view, it can present a high cost of implementation. A sample strategy that allows for reducing the cost of conducting a complete enumeration is the multi-stage cluster sample. In a multi-stage cluster sample, small areas are randomly selected from the geographical area of interest, usually with a probability proportionate to the population size. In this case, recent census data are needed, and then, a complete enumeration of all the households living in the selected small areas is conducted. Ultimately, households to interview are randomly selected from within the enumerated clusters (Miller et al., 2020).

Remote sensing data can be extremely useful to build a data frame when there are no available up-to-date data about the population distribution. There are a few methodologies that adopt technological advances in geospatial data and permit overcoming high costs, limited capacity, and difficulties in supervision and sample selection that often occur when using second-best or nonprobability approaches.

Spatial Sampling Methodology Matrix

One-stage sample	Two-stage sample
<ul style="list-style-type: none"> • Locate dwellings • Random draw 	<ul style="list-style-type: none"> • Sample PSUs with probability PPS • Conduct listing and interview
One-stage cluster sampling	Two-stage cluster sampling
<ul style="list-style-type: none"> • Cluster random sampling • Interview all households in the selected clusters 	<ul style="list-style-type: none"> • Cluster with probability PPS and replacement • Conduct listing and interview

The one-stage sample design locates dwellings using satellite images and then randomly selects the dwelling to be interviewed (Eckman & Himelein, 2020). The two-stage sample design draws primary sampling units with probability proportional to the georeferenced population estimates for each unit and then conducts listing and interviews (Kondo et al., 2014; Eckman & Himelein, 2020).

The one-stage cluster sampling randomly selects clusters with equal probability and then interviews all the household in the selected clusters (Yu et al. 2020), while

the two-stage cluster sampling draws clusters with replacement and with probability proportional to population size till the sample size is reached and then conducts listings and interviews (Miller et al., 2020).

The one-stage has the advantage of eliminating the time between listing and interview, while the two-stage reduces enumerators' mobility, but it may be less statistically efficient due to cluster homogeneity; in other words, people that lived in the same cluster may share similar characteristics. The one-stage cluster is the most efficient in eliminating enumerator mobility and the time between listing and interview, but it is at risk of cluster homogeneity and of overrepresenting rural areas that usually cover a larger portion of the land. The two-stage cluster instead is statistically efficient but at the same time requires covering a larger geographic area. Given potential limitations in resources and time, each of these designs may be better suited for different situations.

Here, the sample design that was customized for the province of San Rafael las Flores in Guatemala is proposed as an example. The municipality of San Rafael las Flores is divided into five micro-regions: San Rafael las Flores, Las Nueces, Media Cuesta, San Rafaelito, and San Juan Bosco. These micro-regions were used to stratify the sample and define the minimum population to survey for reaching representability with a 90% confidence interval. Once the number of questionnaires to collect in each micro-region was defined, the households to be interviewed had to be randomly selected. In the presence of a list of addresses for the entire population, a number of addresses equal to the required sample size could have simply been drawn. The municipality of San Rafael las Flores is composed of a mix of urban agglomerates and rural dispersed dwellings. In the absence of a list of registered households, a different sample strategy was employed. Using distribution population maps and GIS tools, a cluster sample method was adopted, with small geographical units to minimize the clustering bias but also reduce the movement cost for the enumerators' team.

As mentioned above, in this particular application, no list of registered households was available, and a stratification of the sample over five micro-regions was required, i.e., very small geographic units. Finally, cost efficiency was a key requirement. We decided then to use a one-stage cluster sample strategy. A grid of squares with sides of 0.03 radius (approximately 300 m) was generated, as shown in Fig. 3, and the population living in every cluster was calculated according to the high solution population density maps produced by the joint effort between Facebook, Columbia University, and the World Bank (Tiecke, 2017). The high-resolution population density maps issue estimates of human population distribution at a resolution of 1 arc second (approximately 30 m) for the year 2018 (University, Facebook Connectivity Lab and Center for International Earth Science Information Network (CIESIN), Columbia, s.d.). Commercially available satellite images and general population estimates based on publicly available census data and other population statistics are combined with machine learning to generate this extensive database. A cluster size was chosen to balance the trade-off between enumerators' mobility cost and cluster homogeneity (while those clusters that were estimated to contain zero households were excluded.) Then clusters were sampled progressively till the sum of the estimated population reaches the sample size. For example, to

Fig. 3 San Rafael las Flores, Guatemala, high-definition population distribution and 300×300 m grid cropped by the five sub-provinces' borders

sample 350 households, a first cluster would be drawn, and the number of the household contained counted, for example, 20, then a second cluster, counting 5 households, and continuing in this way until the cumulative counting reach 350 households. Additional clusters can also be selected precautionary if the response rate is inferior to 100%. As mentioned before, this method is cost- and time-efficient and allows to consider those households that don't live in stable dwellings, but it has the disadvantage of potentially oversampling rural areas (a smaller concern since this province doesn't contain major urban areas).

Multidimensional Vulnerability Index

The multidimensional vulnerability index (MVI) constitutes an important tool in informing targeted assistance to the most vulnerable households and businesses in the aftermath of crises in the sense that it summarizes the multiple deprivations that they face as the result of the crisis. Its calculations require solid and representative primary data collected just after the crisis. The representativeness of the data is achieved using either the geospatial sampling explained above, which is innovative, costless, and efficient in the case of natural disasters, or other classical sampling methodologies. With a solid sample, data is collected through face-to-face interviews using digital tools. After the data collection phase, datasets are cleaned by looking at duplicates, response errors, and missing values. Then, it becomes possible to calculate the MVI and disaggregate it by households' and businesses' socio-demographic characteristics.

The empirical calculation of the individual MVI for Afghanistan is based on the multidimensional approach developed by Alkire and Foster (2011). The rationale for choosing this methodology is that it is accessible to policymakers. It gives relevance to the joint deprivations faced by individuals, households, or businesses with regard to the indicators that compose the MVI. The MVI is an adjusted headcount ratio index designed to measure vulnerability and can be broken down into incidence, intensity, and dimensional composition.

The indicators included in the calculation of the MVI align with the framework of exposure-sensitivity-adaptive capacity in the case of businesses. Regarding households, although the MVI follows the same framework, the names of the dimensions were adapted to the MPI dimensions to allow comparisons between the two indexes.

Following the COVID-19 outbreak in Afghanistan, UNDP combined satellite imagery and primary data collection to understand the vulnerability of households and businesses in five provinces, Kabul, Balkh, Nangarhar, Kandahar, and Herat. Data were collected in two waves.

Figure 4 shows that businesses were particularly affected and vulnerable in Balkh and Kabul on both waves. Although Kandahar and Herat were the least affected, it can be highlighted that the businesses' vulnerability has more than doubled from wave 1 to wave 2 (Fig. 5). However, by focusing on households, it can be seen that Nangarhar and Kandahar are the provinces with the highest rate of households' vulnerability following the COVID-19 pandemic (UNDP, 2021).

Not only it is possible to take advantage of remote sensing products to optimize the sampling process by accessing up-to-date information about the population distribution or the location of the damages. It is even possible to use remote sensing to guide our research questions. With a pre-analysis based on rapidly accessible secondary data, the target of our assessment can be selected with more precision. This can help us identify more precisely the elements of vulnerability that require a deeper study.

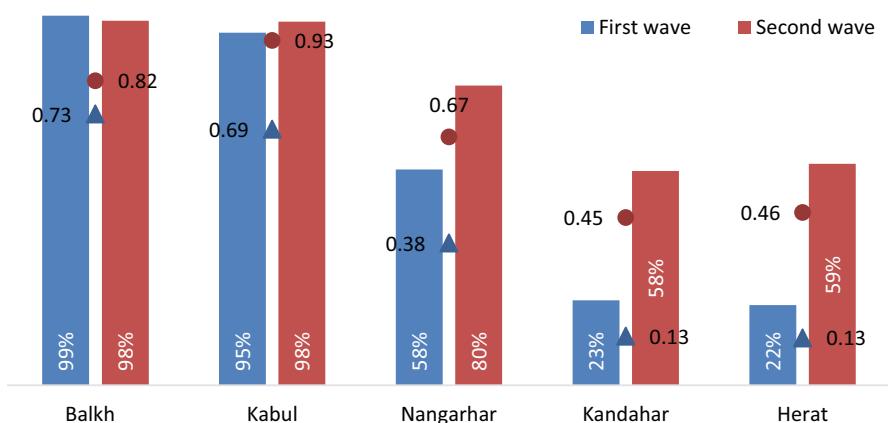

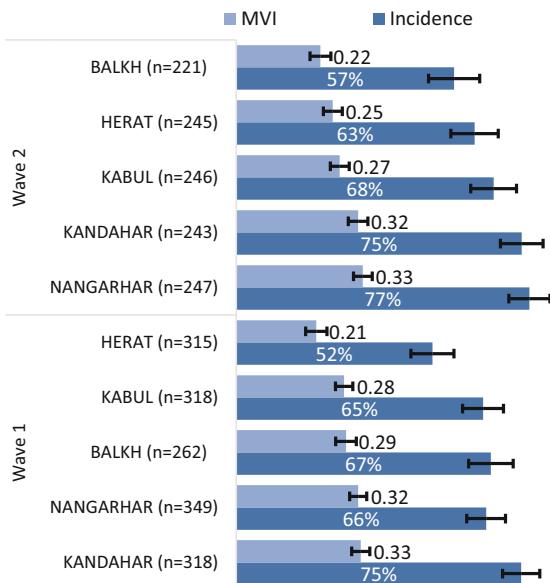

Fig. 4 Incidence and MVI for businesses by regions, both waves. Note: Columns represent incidence, dots and triangles stand for MVI

Fig. 5 Households' vulnerability by provinces

Nighttime Lights

Nighttime lights can improve the monitoring of disaster impacts, at a spatial and temporal resolution that provides ready and localized disaster for the disaster. For instance, nighttime lights are used by Román et al. (2019) to assess electricity restoration efforts in Puerto Rico after Hurricane Maria. They used daily satellite nighttime light data to estimate spatially disaggregated power outages by tracking electricity restoration efforts after the disaster strikes. Nighttime lights can even support monitoring of displacement via satellite-derived observations along with a short message service (SMS)-based emergency survey, like in the case of Cyclone Idai had made landfall in Beira, Mozambique, in March 2019 (Enenkel et al., 2020). In fact, under certain conditions, the spatial extent of power outages can serve as a proxy for disaster impacts and a potential driver for displacement. Moreover, nighttime light can detect changes in the extent of economic activities.

The use of satellite imagery in socioeconomic studies, particularly nighttime lights, has grown in popularity in the last 20 years. Nighttime light intensity captured through remote sensing is used as a proxy for different socioeconomic indicators. An increase in nighttime light may be interpreted as an actual increase in artificial lighting, which is, in turn, caused by an increase in electricity consumption. Therefore, an increase in nighttime lights can be the product of an increase in the intensity of economic activity or other socioeconomic indicators such as population density and quality of life. The use of night lights has many advantages: they can be used as a proxy for economic activity at temporal and geographic scales that are often not

available for traditional data; nighttime lights are available near real time and cheap to obtain; and, finally, they provide a proxy for aggregate economic activity including those that are illicit, providing so more comprehensive information about the economy of a region (Galdo et al., 2020).

Numerous studies have confirmed a robust relationship between nighttime lights and economic activity at the country level. In cross-sectional analysis, nighttime lights show a stronger relationship with GDP than population. Elvidge (Elvidge et al., 1997) finds an R² of 0.97 in the relation between GDP and NTL for 21 countries. In small geographic units, NTL are also a good proxy for human development. Anna Bruederle and Roland Hodler (2018) find that the georeferenced indicator of indicators of household wealth, education, and health, which they built from the Demographic and Health Surveys (DHS), is positively associated with nighttime lights. Their study suggests that the variation in nighttime lights can explain a substantial share of the variation in these socioeconomic indicators. And Pfeifer et al. (2018) use satellite data on nightlight luminosity at the municipality and electoral district level as a proxy for economic activity. They show that infrastructure investments for the 2010 FIFA World Cup in South Africa have a positive effect on economic activities, particularly in the rural areas.

The introduction of Visible Infrared Imaging Radiometer Suite (VIIRS) data has increased the possibilities in socioeconomic research. First, VIIRS nightlight data is more accurate, especially for less aggregated spatial units (Gibson et al., 2021). More specifically, it can detect NTL at higher spatial and radiometric resolutions than DMSP-OLS and sensibly eliminates three critical problems that beset the heritage satellite program: saturation, blooming, and a lack of on-board calibration (Bennett & Smith, 2017). Second, VIIRS nightlight data are a better proxy for local economic activity than are the more widely used DMSP data. VIIRS was proved to predict economic activities also in rural areas of Colombia with even better performance (Pérez-Sindín et al., 2021) and to study the economic impact of the 2015 earthquake in Nepal, violent conflict outbreaks in Afghanistan, and the 2016 demonetization in India (Beyer et al., 2018). The daily, monthly, and annually NTL are available almost in real time with a definition of 15 arc seconds from the NASA Black Marble project. The Nasa Black Marble is a daily adjusted, calibrated, and validated product. It removes cloud-contaminated pixels and corrects for vegetation, atmospheric, snow, topography, and lunar effects in Visible Infrared Imaging Radiometer Suite (VIIRS) (Wang et al., 2018).

Having access to data available at a hyper-local geographic definition and at a daily time interval allows for investigation in spatial and temporal dimensions. Below two methodologies applied to the 2021 Afghanistan institutional crisis are presented: the synthetic control method and the Night Light Development Index. The first is an econometric method to evaluate the effect of an event by comparing affected and non-affected countries over time. The second is an index to measure inequality distribution potentially at a very small geographic definition. VIIRS/NPP Lunar BRDF-Adjusted Nighttime Lights Monthly were employed and all grids that were low-quality flagged were discarded.

Afghanistan suffered a decrease in light intensity after the Taliban takeover. This can be observed in the exemplificative figure below. The province of Kabul presents

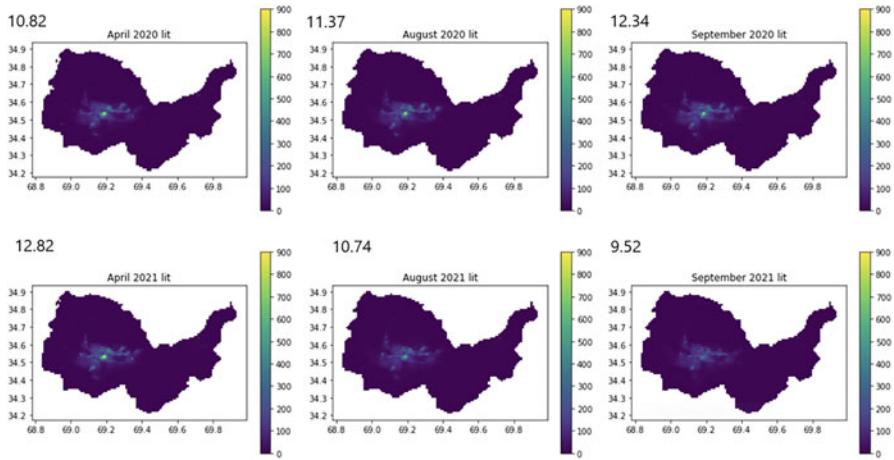

Fig. 6 Kabul province nightlight intensity. Average value of light intensity is shown in the top-left corner

a decrease in light intensity from April 2021 when the conflict started to September 2021. A critic can argue that the difference in light intensity may be due to seasonal effects, but this doesn't appear to be the case as there is not much difference comparing April and September 2020 (Fig. 6). Average light intensity is higher in September 2020 than in April 2020, while in 2021, the trend is the opposite. Moreover, the maximum light intensity per 15 arc seconds grid in September 2021 is 374.5 which is way below its value in the past months.

The synthetic control method, first presented by Abadie and Gardeazabal (2003) and Abadie et al. (2010), is a statistical method used to evaluate the effect of an intervention in comparative case studies. The fundamental idea behind this method is that a combination of units in the donor pool may approximate the characteristics of the affected unit substantially better than any unaffected unit alone. The synthetic control is calculated from a weighted average of the units that form the donor pool. The synthetic control method is a widely applied method in econometrics of policy evaluation. Abadie and Gardeazabal (2003) use a synthetic control approach to assess the impact of terrorism on the GDP per capita of the Basque country from 1955 to 1977. They define that day per capita GDP in the Basque countries declines by 10% relative to the control region without terrorism. Pfeifer et al. (2018) apply synthetic control methods for estimation using satellite data on nightlight luminosity at the municipality and electoral district level as a proxy for economic activity. They find significantly positive, short-run effects before the 2010 FIFA World Cup in South Africa tournament, corresponding to a reduction of unemployment by 1.3 percentage points.

First, the time dimension of the nightlight intensity was analyzed by computing the average light intensity over the entire Afghan territory for every month from 2016 to 2021. As shown in Fig. 7, projecting this trend (blue line in the image below), it can be seen that there is a seasonal effect on the light intensity; indeed,

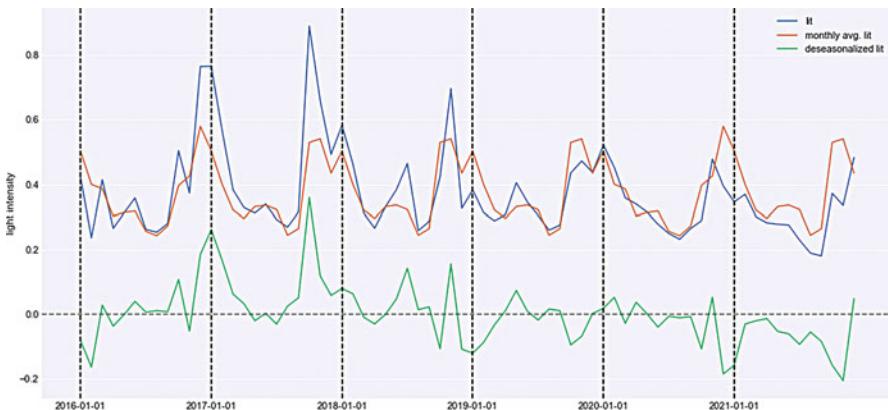

Fig. 7 Nighttime light intensity observed values, monthly average, and deseasonalized values

nightlight intensity decreases during the summer months (the orange line represents the average light intensity by month). By subtracting the monthly average (orange) from the actual data (blue), the deseasonalized light intensity (green) that reveals a decreasing trend was calculated. Particularly 2021 presents values below the average annual values.

Then a synthetic control was built using as donors Central Asian countries (Pakistan, Iran, Turkmenistan, Uzbekistan, Tajikistan, Kyrgyzstan, Mongolia, Myanmar, Syria, Iraq, Kazakhstan, Oman, Yemen, and Bhutan) that weren't directly affected by the institutional shock, and it was compared with the Afghanistan trend. The synthetic group is trained using nighttime light intensity monthly collected for 1 year before the Taliban officially took over the government. Using a synthetic control method, it can be observed in Fig. 8 that the trend after August is increasing for the observed and the synthetic series, probably because of an increase in electricity demand during the winter months. It can also be noticed that such an increase is less intense compared to the estimated trend (red dotted line) in the absence of the Taliban suggesting that the Taliban takeover may be the cause of electricity consumption inferior to the expected value.

This study should be considered preliminary as more advanced studies might be conducted in order to find a correct pool of countries to better approximate the Afghanistan pre-crisis trend. Moreover, while selecting the donor pool, the fact that these neighboring countries may have been indirectly exposed to the Afghan crisis should have been kept in account, for example, by the migration from Afghanistan. Therefore, more variables should be included in the model to balance the contribution of the units in the donor pool.

The “Night Light Development Index” (NLDI) measures inequality in the distribution of nighttime lights per capita. This index doesn't require data on monetary income, and it provides a spatial depiction of differences in development within countries. The spatial inequality is obtained by computing the Gini index of the distribution of nighttime light intensity divided by population. Like

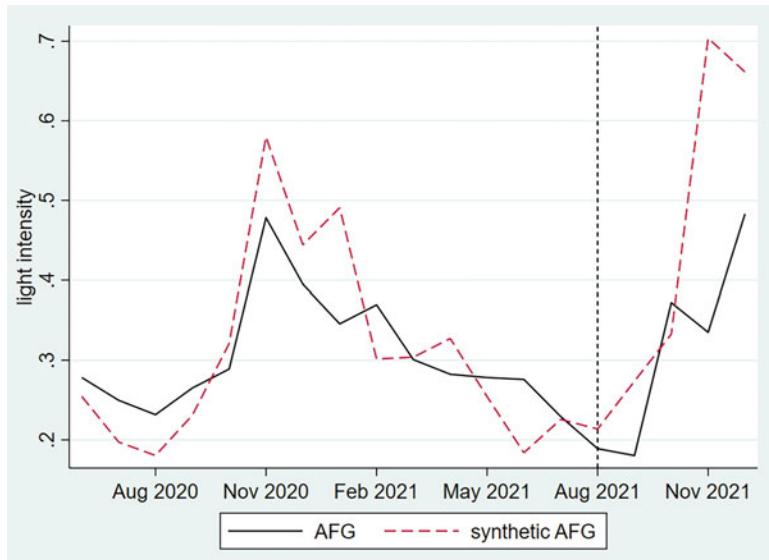

Fig. 8 Synthetic control method

the Gini index, the NLDI is used to measure the dispersion of a variable across a population, region, or nation in order to determine the inequality distribution, and it takes values in a range from 0 (equality in distribution) to 1 (Elvidge et al., 2012). One of the advantages of this measure is that it can be computed at the country, subregional, and grid levels. By using national-level NLDI, Elvidge et al. (2012) found strong correlations with the Human Development Index, electrification rates, and poverty rates, while the NLDI does not correlate with the traditional income Gini. They conclude, in fact, that NLDI is a form of development index rather than a monetary index. Ivan et al. (2020) found that the NLDI calculated from nighttime light (NTL) satellite images proved to be a good proxy for the real-time measuring of economic output in Romania. Levin and Zhang (2017) by analyzing the Central Asian countries of Kazakhstan, Kyrgyzstan, Tajikistan, Uzbekistan, and Turkmenistan discovered that per capita lighting is related to per capita GDP.

The NLDI takes values 1 when inequality is at its maximum. Overall, a decrease in inequality was detected during conflict months, followed by an increase in inequality from October onward (Fig. 9). A plausible interpretation suggests that the conflict had a larger impact on relatively wealthier areas, while under the Taliban regime, poorer areas have seen a decrease in light intensity per capita, thus increasing inequality. At the district level (Fig. 10), it can be observed that from April to September 2021, the light intensity distribution in the central and central-east areas becomes more unequal (this can be seen as a shift to darker red in Fig. 10).

Despite empirically observing that the variation in NTL is different in the year of the conflict with respect to the previous year, further investigations should be

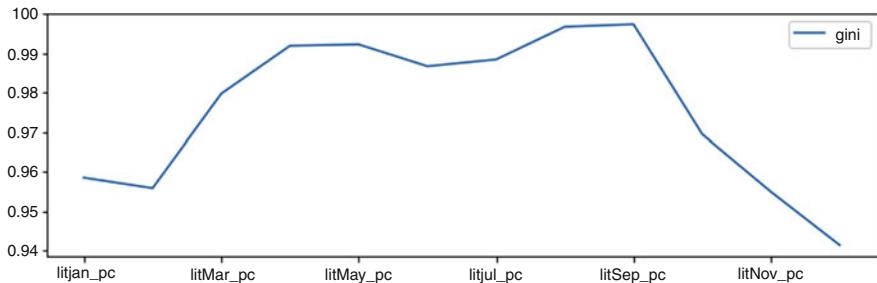

Fig. 9 Gini index at the country level for January–December 2021

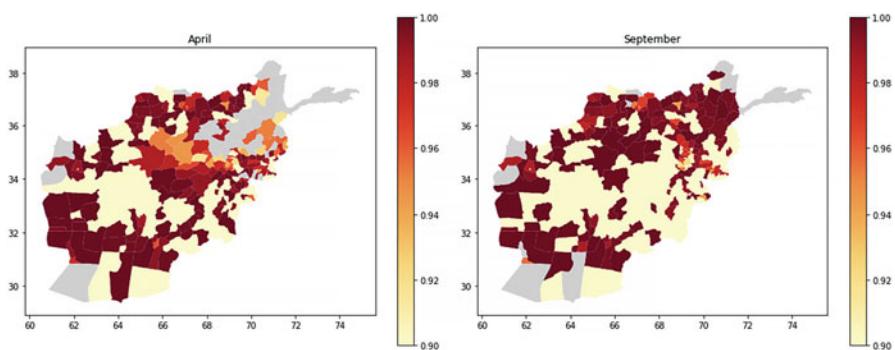

Fig. 10 Gini index measures the inequality distribution among sub-provinces (Administrative level 2) comparing April and September 2021

conducted to exclude the seasonal effect as a possible cause of the NLDI variation, for example, comparing annual data that are free from seasonal effects.

Conclusion

In this chapter, it was examined how different remote sensing tools play a role in relief, reconstruction, and recovery support after a natural or human-made disaster. Starting with satellite images and UNOSAT damages classification, it was discussed how remote sensing tools help to identify the most affected areas. Indeed, knowing where is optimal to address the disaster assessment efforts can save time and costs and produce tangible benefits for rapid and effective decision-making for relief and recovery. Moreover, having precise information about the location of the buildings makes it easier to identify those that are damaged. Even when it is not feasible to collect information for every damaged building or afflicted household, this information can support an effective random sampling to obtain a representative analysis. Population estimates generated by satellite images are another way to obtain a representative sample, especially when a study on the socioeconomic impact of a

disaster lacks of an up-to-date sample frame. High-definition population distribution maps can tell us about the distribution of the population and build representative samples to support primary data collection. Finally, it was observed how elaboration of satellite images, like nighttime lights, can provide data about socioeconomic factors in the case of the impact of institutional instability in Afghanistan. Such data have the advantage of a high geographic definition and timely availability. On the one side, there is a benefit from almost real-time hyper-localized indicators, but we must also consider the implicit assumption that the use of such remote sensing tools implies. For example, the use of nighttime lights is founded on the thesis that nighttime lights change along with socioeconomic indicators. Even if the correlation between nighttime lights and economic activities is well accepted by the academic community, nighttime lights remain a proxy for socioeconomic outcomes, and other unobserved causes can concur to a variation in nighttime lights. For this reason, traditional data collection plays an essential role in corroborating unconventional data applications. Remote sensing tools can provide rapid information to coordinate the intervention and in a second moment optimize the data collection plan, while primary data collection can integrate and verify the results obtained from the remote sensing data acquisition.

All considered, it is undeniable that remote sensing is a crucial tool in damage and socioeconomic assessments. Not only it is cost- and time-effective, but it also opens new frontiers to the exploration of data and methodologies that can shed light on critical events that afflict developing countries. The low cost of acquisition, standardization in data production, global availability, and robustness of validity allow to conduct multiple analyses and provide a well-rounded description of a natural or human-made disaster. For instance, an event can be studied in its temporal and spatial dimensions, observing how economic activities, emissions, and population movements reacted. In conclusion, there is an expectation that the increasing adoption of remote sensing generated data will find more applications in contexts where several inexpensive – although uncertain – measures can substitute single expensive measures.

Abstract

The use of social media today is not only ubiquitous and an integral part of everyday life but is also increasingly relevant before, during, or after emergencies. Data produced in these contexts, such as situational updates and multimedia content, is disseminated across different social media platforms and can be leveraged by various actors, including emergency services or volunteer communities. However, the dissemination of several thousand or even millions of messages during large-scale emergencies confronts analysts with challenges of

information quality and overload. Hence, crisis informatics as a research domain seeks to explore and develop systems that support the collection, analysis, and dissemination of valuable social media information in emergencies. This chapter presents the social media API (SMA), which is a multi-platform service for gathering big social data across different social media channels and analyzing the credibility and relevance of collected data by the means of machine learning models. Based on the lessons learned from both the implementation process and user-centered evaluations in multiple emergency settings, this chapter discusses core challenges and potentials of the SMA and similar services, focusing on (1) the multi-platform gathering and management of data, (2) the mitigation of information overload by relevance assessment and message grouping, (3) the assessment of credibility and information quality, and (4) user-centered tailorability and adjustable data operations.

Keywords

Big social data · Social media · Crisis informatics · Information refinement · Multi-platform services

Introduction

As of today, social media are not only well established for a variety of purposes in everyday situations (Robinson et al., 2017) but are also used during natural and man-made crises and conflicts as a valuable source of information (Reuter & Kaufhold, 2018; Riebe et al., 2021). Social media services coupled with smartphone technologies offer a permanent opportunity to create and gather valuable information, such as situation updates, eyewitness reports, multimedia files, or public mood information, anywhere at any time in large quantities. Thus, the multidisciplinary field of crisis informatics has combined knowledge, methods, and theories from computer and social science to investigate the effective usage and development of information and communication technology for the mitigation, preparedness, response, and recovery regarding critical situations (Palen & Anderson, 2016). Even though the emerging *big social data* (Olshannikova et al., 2017) has the potential to enhance emergency services' situational awareness (Vieweg et al., 2010) and establishes new bidirectional communication channels with both citizens and volunteer communities (Kaufhold & Reuter, 2016), the adequate deployment or implementation of *social media analytics* still presents a challenge (Stieglitz et al., 2018). Not only is relevant data scattered across numerous social media platforms (Hughes et al., 2014; Reuter et al., 2015a), but also technical or business-oriented restrictions limit data access (Reuter & Scholl, 2014), and the analysis of data must conform with the data exchange formats used (Reuter et al., 2016b). Furthermore, issues of chaotic use, serious information overload, and low information quality arise during emergencies and thus reduce potential contributions to emergency managers' situational awareness (Kaufhold, 2021; Kaufhold et al., 2019; Plotnick & Hiltz, 2018).

This chapter introduces related work on the challenges and potentials utilizing big social data by the means of social media analytics in the multidisciplinary field of crisis informatics. Based on this, it presents the architecture and development of the social media API (SMA), which is a multi-platform service for the gathering, processing, storage, and querying of social data from Twitter, Facebook, Flickr, Instagram, Reddit, Tumblr, and YouTube. The SMA has been deployed over several years in various application scenarios of the crisis management domain to evaluate its practical applicability, potentials, and limitations. Thus, this chapter continues with a discussion of our experiences and findings with respect to both the gathering of social media data across multiple platforms and their subsequent preparation for analysis. The results highlight that conversion and processing of heterogeneous social data into a unified data format are feasible (specification), although some metadata must be computed for comparative analysis if it is not provided by the source platform (comparability). It is shown how machine learning can be utilized to identify credible and relevant emergency information (classification), even though the context-dependent and highly individual character of information quality must be considered when analyzing social data (interpretability). In order to align tools with end-user objectives, sufficient search options and filter parameters (tailorability) using logical query operators (queryability) are required. Still, our findings show that social media platforms are subject to continuous change. Thus, frequent adjustments of social media tool implementations are required (adjustability).

Related Work

The increasing dissemination of mobile devices and the growing use of social media, such as Facebook or Twitter, led to the emergence of the term of *big social data*, which “is any high-volume, high-velocity, high-variety, and/or highly semantic data that is generated from technology-mediated social interactions and actions in digital realm, and which can be collected and analyzed to model social interactions and behavior” (Olshannikova et al., 2017). In addition to the regular usage of social media platforms, a variety of application programming interfaces (APIs) render the automatic retrieval and processing of large quantities of data feasible. In response, social media analytics has emerged as a novel research field, which is concerned with the process of collecting, analyzing, and interpreting social media data with regard to involved actors, entities, and relationships (Choi et al., 2020; Stieglitz et al., 2014). To achieve these goals, different methods and tools are combined, enhanced, and modified for the analysis of big social data (Fan & Gordon, 2014; Holsapple et al., 2018; Lee, 2018; Stieglitz et al., 2018). Especially against the background of large-scale emergencies that result in the dissemination of vast quantities of messages on social media (Reuter et al., 2019), this research area becomes increasingly important as emergency services are faced with the issues of severe information overload and poor information quality. Information overload can be induced by a number of issues, including personal factors; characteristics and parameters of information, tasks, and processes; organizational design; or particular information technologies

Table 1 Overview of existing mitigation techniques for information overload during emergencies, crises, or disasters

Technique	Description
Keyword search engine	Execution of simple keyword searches or complex searches using Boolean operators such as “AND,” “OR,” and “NOT,” either in embedded web interfaces or by using search APIs (Imran et al., 2015)
Metadata filtering	Filtering of information by different types metadata, e.g., social media platform, language, time, or location, often in combination with search functionalities (Kaufhold et al., 2020b)
Interactive visualizations	Usage of interactive visualizations, e.g., timelines, charts, maps, or word clouds, that enable a reduction of the displayed data to a particular subset using a specific gesture (Onorati et al., 2018)
Message classification	Application of supervised machine learning models for the classification of information in terms of relevancy (Mohanty et al., 2021) or according to humanitarian categories (Alam et al., 2020)
Message clustering	Categorization of similar text documents into groups utilizing similarity metrics and unsupervised machine learning techniques (Bayer et al., 2021; Fahad et al., 2014; Huang et al., 2021)
Information summarization	Use of automated and real-time algorithms based on extraction or abstraction techniques to generate comprehensive information summaries of individual disaster events (Rudra et al., 2018, 2019)

(Eppler & Mengis, 2004; Roetzel, 2019). In light of the characteristics of information and technology, information overload can be defined as “[too much] information presented at a rate too fast for a person to process” (Hiltz & Plotnick, 2013). Research has identified numerous potential consequences of information overload (Bawden & Robinson, 2020), including the risks of getting distracted by data material irrelevant to the current task, as well as of processing and presenting data in an inappropriate way (Keim et al., 2008).

Past research in crisis informatics studied and developed multiple techniques and artifacts for the mitigation of information overload during large-scale emergencies (Table 1). An initial and intuitive step for the identification of relevant (and the exclusion of irrelevant) information is the utilization of *search engines* that enable searches with basic keyword-based or complex Boolean queries. Whereas these are directly accessible to regular users of social media platforms, platform search APIs enable developers the integration of acquired results into more advanced third-party applications (Imran et al., 2015). These types of applications frequently enhance search engines with the option to *filter information* by different types of metadata, including social media platform, language, time, or location (Kaufhold et al., 2020b). Furthermore, *interactive visualizations* (e.g., timelines, charts, maps, or word clouds) facilitate the reduction of the displayed data using specific gestures (Onorati et al., 2018).

Furthermore, machine learning algorithms may offer assistance for the identification of relevant information after data collection. For instance, supervised machine learning techniques are often applied for *message classification* tasks, such as the binary classification of information relevancy for a specific type of emergency (Habdank et al., 2017; Mohanty et al., 2021) or the classification of information

according to humanitarian categories, including infrastructure and utilities, donations and volunteering, affected individuals, sympathy and support, caution and advice, other types of useful information, or not applicable (Alam et al., 2020; Burel & Alani, 2018; Pekar et al., 2020). Still, these techniques are often not universally applicable (i.e., designed for specific events), and their performance is dependent on the time-consuming labeling of data as well as the adequate training of models. In contrast, *message clustering* techniques categorize similar messages into groups utilizing similarity metrics and unsupervised machine learning techniques, thus not requiring labeled data for training (Bayer et al., 2021; Fahad et al., 2014; Huang et al., 2021). Existing research found that the “chunking” of messages from social media by distinct tools can have a positive effect on the disposition of emergency managers to utilize social media in emergencies (Rao et al., 2017). Since clusters often are not self-explanatory, they require a useful summary of the clusters’ contents or a descriptive labels (Gründer-Fahrer et al., 2018). Thus, automated and real-time algorithms using extraction or abstraction techniques for *information summarization* can be applied to generate summaries of entire datasets or subsets of events (Rudra et al., 2018, 2019).

Besides the rich availability of techniques to deal with issues of information overload and quality, a market study of 45 tools for social media analytics (Kaufhold et al., 2020b) highlights that most solutions are designed for commercial purposes and thus are not tailored for the objectives of the emergency management domain. Although they often provide multi-platform capabilities for communication and monitoring, they lack algorithms for detecting credible or relevant information in emergencies. While expert tools such as AIDR permit the annotation of data, enable the classification of disaster-relevant information in Twitter (Imran et al., 2014), and can be combined with an interactive monitoring dashboard to enhance situational awareness (Aupetit & Imran, 2017; Onorati et al., 2018), it still requires multi-platform tools – tested in user-centered evaluations – to support (I) the coordination of emergency response in volunteer communities, (II) the interaction between emergency services and volunteer communities, and (III) the situational awareness of emergency services.

Architecture and Deployment of a Multi-platform Social Media API

The SMA enables the gathering and processing of big social data. Using the underlying social media platforms as foundation, it comprises several services that can be leveraged by different client applications. Though initially intended as an enabling technology for emergency management, its design enables the support of a multitude of use cases in different application domains. To facilitate the acquisition of big social data and subsequent analysis, our initial step was the specification of a service for the gathering and processing of social media content. *Gathering* in this context refers to the capability to conduct one-time searches or to continuously aggregate social media activity (e.g., posts, news, or photos) from multiple platforms (Twitter, Instagram, Facebook, Reddit, Flickr, YouTube, and Tumblr) in a uniform

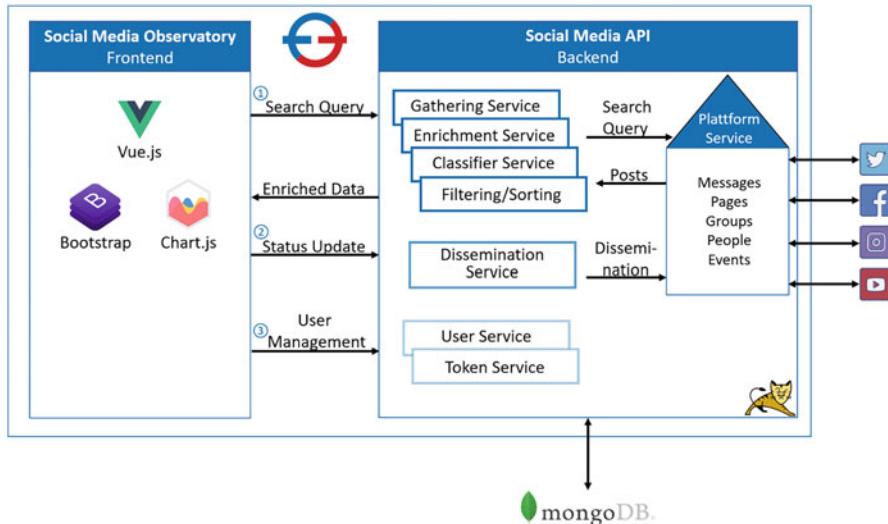

Fig. 1 Social media API architecture in conjunction with the Social Media Observatory client application. (Kaufhold et al., 2020a)

manner leveraging multiple search queries or filtering criteria. Moreover, *processing* refers to the SMA's capability to access, manipulate, enrich, store, and disseminate social media activities.

The SMA is implemented as a web-based application following a service-oriented architecture (Fig. 1). Designed as a Java Tomcat application, it utilizes the Jersey Framework for REST services and the MongoDB database for document-oriented data management. The underlying social media platform APIs, such as the Twitter Search API or the Facebook Graph API, are integrated by means of multiple libraries. To accommodate the diversity of data access and structures, the Activity Streams 2.0 Core Syntax (AS2) is used to process and store all gathered social media activities. Moreover, the SMA leverages Java interfaces that enable standardized implementations of additional social media, provided their APIs offer suitable data access. Although there are multiple service templates, developers must apply the *message service interface* as the basic template, which requires the implementation of four methods to search for multiple messages as well as to get, modify, or delete a single message. The SMA serves as foundation for multiple client applications which were deployed for three different scenarios.

Scenario I: Coordination of the Emergency Response in Volunteer Communities

Independently of the actions taken by official emergency services, volunteer communities often spontaneously emerge and complement relief efforts by performing tasks such as dike building and the distribution of material donations (Kaufhold & Reuter, 2016).

These tasks are increasingly coordinated across multiple social media. Therefore, a Facebook application named XHELP was developed allowing users to gather and disseminate information across media (e.g., Twitter and Facebook) and across channels (e.g., Facebook pages and groups) (Reuter et al., 2015a). It is specifically designed for digital moderators in emergency contexts who coordinate volunteers and material resources by providing an overview of their own joined groups, liked pages, and published posts. The central dashboard “My Posts” (Fig. 2) displays an overview of the user’s communication threads, comprising not only posts created with XHELP but also comments and posts set up on the source platform. The user has the options of (1) collapsing or expanding comments on a communication thread, (2) responding to any or deleting own comments, and (3) removing or finalizing own communication threads. The finalizing functionality offers the user the opportunity to draft a posting to notify relevant groups, media, and pages (e.g., if an emergency-related problem is solved). Subsequently, the post will disappear from the central dashboard but will still be accessible from the navigation bar. In addition, the cross-media search enables looking for publicly and privately (e.g., if the user belongs to a closed Facebook group) shared Facebook and Twitter posts and filtering them by time, geolocation, and radius. Due to the Social-QAS integration, the user may also sort their search results according to particular evaluation criteria.

Despite the content management features of XHELP, it is often hard for volunteer communities to find high-quality information that is tailored according to their specific situational needs. A social quality assessment service (Social-QAS), which strives to facilitate the assessment of social media content through the customizable weighting of information quality criteria, was developed and integrated into the

The screenshot shows the XHELP application interface. On the left is a sidebar with navigation links: SEARCH, MY POSTINGS (Create new Posting, Exemplarisch Gesuch), PRIVATE MESSAGES (Other Messages), GROUPS (Privates Helfer- und Hilfenn..., HJA Uni Siegen, Test der Applikation Freiwi..., Orkan Xaver - Hilfe um Laue..., Testgruppe 2014-02-04, UNI SIEGEN, Hochwasser Magdeburg - Hilf..., Hochwasser 2013 Helfen, spe..., HochwasserNiedersachsen - B..., Risiko Evolution), PAGES (Gemeinschaft unabhängiger T..., Hochwasser Niedersachsen), and SETTINGS. The main area is titled 'DESCRIPTION' and contains text about the application's purpose and features. Below this is a section titled 'MY POSTINGS' which lists several posts with their details and status indicators (green checkmark, red X, blue arrow).

SMO to mitigate these issues (Reuter et al., 2015b). Since the diverse circumstances of emergencies necessitate differing methods of assessment, the opportunity to combine these techniques could contribute to the improvement of quality assessment practice (Ludwig et al., 2015a). The concept encompasses 15 methods for the assessment of social media content, subdivided into four groups: metadata (author frequency, temporal proximity, local proximity, followers/likes, media files), content (frequency of search keywords, stop words), message classification (sentiment analysis, negative and positive sentiment, named entities, emoticons, slang), and scientific methods (term frequency-inverse document frequency, Shannon information theory). Social-QAS allows end users to determine the subjective information quality by selecting and weighting several evaluation methods. As part of an exemplary implementation in XHELP, users have the option of searching for information based on various quality parameters in order to conduct a quality assessment (Fig. 3). For this purpose, users can select and weigh assessment dimensions by the means of sliders.

Scenario II: Improving the Interaction between Emergency Services and Volunteer Communities

Although volunteer communities have the potential to make valuable contributions to crisis response, the sometimes chaotic and dangerous activities of citizens initiated via social media may lead to an increased complexity of tasks, uncertainty, and

The screenshot shows the 'SOCIAL MEDIA VOLUNTEERS-COORDINATION' interface. On the left, there are sections for 'SEARCH', 'MY POSTINGS', 'PRIVATE MESSAGES', 'GROUPS', 'PAGES', and 'SETTINGS'. The 'SEARCH SETTINGS' panel on the right contains fields for 'Search Term' (set to 'Pege'), 'Set Networks' (Facebook, Twitter checked), 'Define Period' (2013-12-02 00:00 - 2013-12-09 00:00), 'Select Location' (Hamburg, Deutschland), 'Search Perimeter (km)' (50.0), and a 'Search' button. Below these are sections for 'Evaluate Message Metadata', 'Evaluate Message Content', 'Evaluate Message Classification', and 'Evaluate with Scientific Methods', each with a slider from 'nonrelevant' to 'relevant'. At the bottom, the 'SEARCH RESULTS [54]' section shows two entries: 1. A tweet from @welt about a flood in Hamburg. 2. A post from Xaver (@orkantief_Xaver_aktuell) about a flood in St. Pauli.

Fig. 3 The social quality assessment service (integration in XHELP) for tailorabile data assessment during gathering and post-processing

pressure for emergency services (Perng et al., 2012). Thus, it is of utmost importance that the activities of both emergency services and volunteer communities are well-aligned. In an effort to improve their interaction, the web application CrowdMonitor (Fig. 4) was designed to enhance the meaningfulness of spontaneous volunteers' activities for emergency services during emergencies (Ludwig et al., 2015b). One challenge in crisis management is to gain awareness of activities of spontaneous volunteers and to coordinate these activities with those of the formal emergency services. To this end, the tool combines collective processes tracked through social media by the SMA with individual activities sensed by mobile devices. First, CrowdMonitor applies the SMA to allow responders the passive collection and display of information from social media (generated by ordinary people without their knowledge). Second, requests for specific information or targeted alerts can be created, which subsequently can be sent to users of a corresponding mobile app (within a specified area). Thus, CrowdMonitor combines the potential of a synchronized view of mobile-gathered data and information acquired on social media with additional capabilities to interact with people in order to provide situation pictures and reports during emergencies.

In long-term and large-scale emergencies (e.g., forest fires or floods), a large number of volunteers come together to help those affected. On the one hand, the helpers coordinate online within social media, but on the other hand, they travel physically to the site, where a number of local activities are also required. While CrowdMonitor is an interface designed for emergency services, important information about the ongoing event as well as current offers and requests for help must be disseminated to both the affected population and volunteers on-site. To this end, the public display application City-Share (Fig. 5) maintains a robust infrastructure for

communication and additionally incorporates situated crowdsourcing mechanisms to manage offers and requests related to on-site activities (Ludwig et al., 2017).

In this process, relevant information from social media is displayed based on the SME and is used to help coordinate volunteers. At the same time, important location-related information, such as warnings or assembly points, is provided. City-Share helps to improve disaster resilience in communities, particularly in terms of a collaborative type of resilience that emerges at the local level between official actors and spontaneous volunteers or involved citizens.

Scenario III: Enhancing the Situational Awareness of Emergency Services

Thousands of potentially relevant messages may be disseminated during an emergency, which can result in information overload. The Emergency Service Interface (ESI) was developed to improve emergency managers' situational awareness and decision-making by “transferring high volume, but unclear information content into low volume and rich content suitable for emergency services” (Moi et al., 2015). The central dashboard (Fig. 6) combines *app alerts*, which are received from a separate mobile emergency application (Kaufhold et al., 2018), and *social media alerts*, which are computed based on the data provided by the SMA (Kaufhold et al., 2020b; Reuter et al., 2016a), in a map and list view. Social media alerts consist of a set of classified messages with a similar context, which is determined by event type, platform, language, keywords, relevancy, quality, time, and location. Each alert

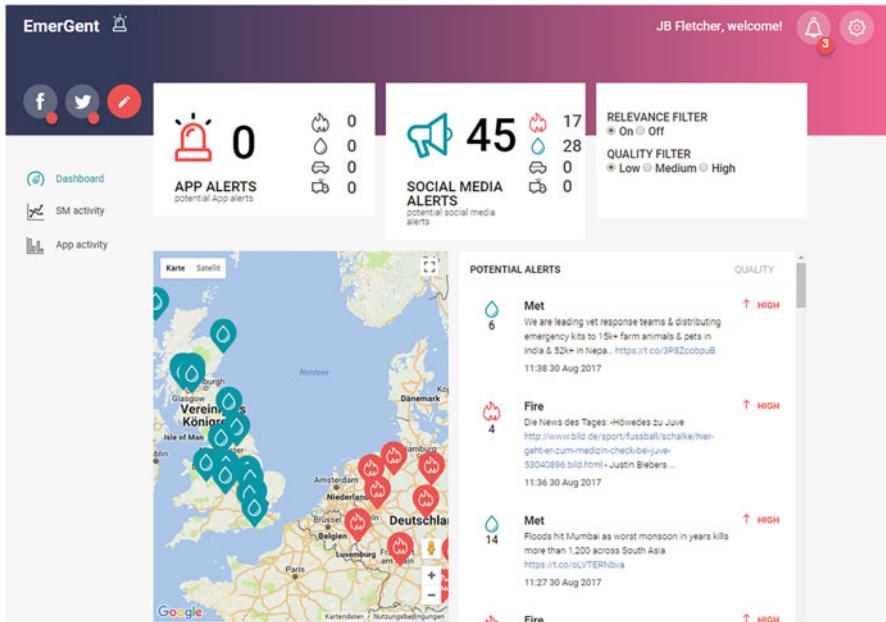

Fig. 6 Emergency Service Interface (ESI) for mobile and social media alerts

consists of multiple messages from different social media if they belong to the same setting. However, several steps are conducted before messages are grouped into alerts. After an initial data gathering and keyword-based filtering, relevance classifiers (e.g., for fire and flood scenarios) are used to reduce irrelevant information. Then, an information quality component measures the believability, completeness, relevancy, timeliness, and understandability of the remaining messages before they are grouped into social media alerts and directed to the interface. On the interface level, emergency managers can enable or disable both the relevance and quality filters and also click on alerts to investigate the individual messages.

Despite the generally positive reception of the ESI by involved emergency services, the tool lacked the capability to configure and tailor the analysis according to end-user requirements (Kaufhold et al., 2020b). The Social Media Observatory (SMO) is an interface that enables end users to monitor, analyze, and classify social media messages (Kaufhold et al., 2020a). More specifically, it facilitates the creation of social media datasets (based on one-time or continuous searches of the SMA), management of SMO users (e.g., to create, edit, or delete users), creation of machine learning classifiers, and dissemination of messages. In its first version, the SMO was simply an interface for the SMA to create and manage social media datasets (Reuter et al., 2016b). Now, its central feature is a real-time capable dashboard (Fig. 7) that displays characteristics of the loaded dataset (e.g., number of results, post frequency, sentiment, media, and language) besides visualizing posts on a map and in social feeds. If no exact location (green markers on the map) is given, named entity

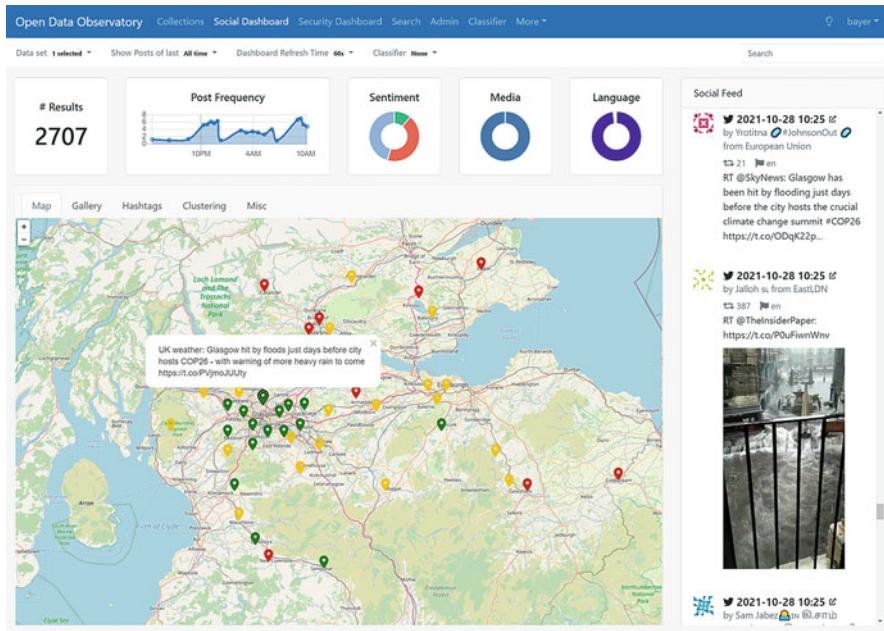

Fig. 7 Social Media Observatory (SMO) dashboard with interactive charts, feed, and list view

recognition is used to attempt extracting location information from either the individual post (yellow markers) or the author's profile (red markers). However, posts without a location will be displayed in the social feed only. Alongside with some basic settings (e.g., dashboard refreshing time), the dashboard supports visual interactive filtering (e.g., by clicking on the red part of the sentiment pie charts, only messages with negative sentiment are displayed in the interface). Furthermore, the SMO features an annotation tool to create datasets for machine learning classifiers. In this way, classifiers for credibility and relevance assessment can be designed and used to filter out unreliable and irrelevant information from the dashboard view. Additionally, the interface allows emergency services to correct algorithmic misclassifications to improve the classifiers' accuracy.

Discussion of Challenges

In order to evaluate these client applications individually, cognitive or scenario-based *walkthroughs* requesting participants to “think aloud” (Nielsen, 1992) were combined with follow-up semi-structured *interviews* to encourage the reflection on the evaluation procedure. For the results of both the walkthroughs and interviews, audio recordings and transcripts as material for a subsequent “open coding” analysis (Strauss & Corbin, 1998) were created. The evaluations’ philosophy followed the

Table 2 Key evaluation topics for client applications of the social media API

	Multi-platform usage	Information overload	Information quality	Tailorability
XHELP (N = 20)	×			×
Social-QAS (N = 20)	×	×	×	×
CrowdMonitor (N = 28)			×	
City-Share (N = 27)	×	×		×
Emergency Service Interface (N = 33)	×	×	×	
Social Media Observatory (N = 12, D = 2)	×	×	×	×

notion of “situated evaluation” (Twidale et al., 1994) drawing on qualitative methods and the involvement of domain experts to derive conclusions about real-world technology usage. Furthermore, machine learning algorithms for credibility and relevance assessment were evaluated with regard to accuracy, precision, recall, and time (Kaufhold et al., 2020a, 2021a). In both cases, the most suitable models were integrated into the SMO. Based on the lessons learned, the upcoming section presents potentials and obstacles of the multi-platform gathering and analysis of social media data (Table 2).

Multi-platform Gathering and Management of Social Media Data

Keyword parameters represent a problem for querying data across multiple social media platforms since the APIs of different platforms support various differing notations and types of logical query operators, such as OR, AND, NOT, parentheses, or phrases. Thus, there is a necessity for a uniform query language and layer that facilitates the translation of the uniform parameters to their platform-specific equivalents. Whereas Twitter and YouTube employ a uniform query syntax for basic logical operators with their API, Instagram’s API does offer a functionality for searching individual tags within media descriptions instead of keyword-based searches, and Facebook’s Graph API is restricted to the AND operator. For both platforms, this necessitated a downstream implementation of logical operators using the parser generator ANTLR. For example, the conjunction OR was transformed into several individual requests to the API. However, this resulted in a faster quota limit exhaustion (Reuter & Scholl, 2014) due to the greater quantity of sent requests (OR) and the acquisition of irrelevant data (NOT). Particularly in the case of quota-limited APIs, such downward implementations can reduce the access to available data.

The diverse social media platforms not only provide numerous information types such as multimedia files text and metadata (e.g. the number of retweets or interactions) but are often subjected to differing standards (e.g. tweets are restricted to a maximum of 280 characters). During our research on a common and standardized

approach for the representation and storage of gathered social media information the AS2 format in combination with MongoDB was found to be best suited for the task. While the flexibility of MongoDB's document-oriented approach enables the storage of clearly structured documents with a varying quantity of attributes AS2 follows an interoperable specification for the storage of attributes. However the possibility to compare and analyze social media activities is constrained with regard to diverging metadata. As it was impossible to map all attributes to the AS2 specification it was necessary to implement a custom class with divergent attributes for the mapping of platform-specific metadata such as the number of likes or retweets.

Besides, there exist two further valuable data types apart from publicly available data. First, data that is restricted to a distinct social media platform can be computed for the others. For example, there is the possibility to extract embedded mentions, hyperlinks, or tags from social media activities if not provided by metadata. Second, individual social media platforms lack some data required for quality assessment operations. Thus, the SMA is capable of manually computing classification attributes (slang conversion, emoticon conversion, positive or negative sentiment), content attributes (number of words, number of characters, words-to-sentences ratio, average length of words, entropy, number of syllables per word, number of punctuation signs), and metadata attributes (media files, location, tags, hyperlinks, language). Nonetheless, there are limitations to standardization, as it is uneconomical to map all available metadata attributes across all social media platforms into a singular specification. Against this backdrop, the storage of the native format as a string attribute per activity could be a feasible approach. This may also facilitate the transfer of data to client applications that support only certain native data formats.

Mitigating Information Overload by Relevance Assessment and Message Grouping

The presented client applications demonstrate several measures to reduce information overload during emergencies. For instance, a sophisticated information processing pipeline was established in the backend of ESI, which first gathers social data by keywords and metadata, then filters out irrelevant and incredible information using machine learning, and finally groups the remaining messages into social media alerts. By reducing social media content into alerts, the amount of displayed information on the ESI was reduced significantly. In their base implementation, social media alerts combine messages from all implemented platforms that are only connected by geographic and/or chronological proximity (i.e., Euclidean distance) since a more sophisticated clustering approach could not be realized within the scope of the project. A click on the alerts allows the user to inspect details on demand, i.e., to show the individual messages grouped into an alert. However, since the focus of the project was a human-centered evaluation of the tool, the used relevance classifiers were based on naïve Bayes, and the same classifier, which only achieved moderate classification accuracies, was applied to all implemented social media platforms (Kaufhold et al., 2020b). While the use of weak-performing classifiers

might result in the overlooking of important information by emergency managers, another challenge lies in the time-consuming nature of annotating machine learning datasets – in our case, ideally for a high-classification performance across multiple platforms – under the time-critical constraints of emergencies.

To address these issues, first, a random forest algorithm with good performance during relevance classification that incorporates social media metadata into a batch learning approach and, second, a novel relevance classification approach that includes active, incremental, and online learning to achieve a reduction of the required amount of labeled data and a correction of algorithmic misclassifications using feedback classification were developed (Kaufhold et al., 2020a). With the second approach, a well-performing classifier was created that requires only a quarter of the labeled data in comparison to the conventional batch learning approach. Still, since the classifiers were trained based on data from a single social media platform, further research is required on how well these perform on multi-platform data or how to design classifiers based on annotated multi-platform datasets. Furthermore, based on an improved relevance filtering, the grouping of similar messages into alerts could be further improved by more efficient (e.g., based on word embeddings) clustering algorithms (Bayer et al., 2021).

The Context Dependency of Credibility and Information Quality Assessment

The evaluations revealed issues of credibility and overall information quality on different levels and for most emergency scenarios. For instance, it was questioned whether the content of a post is actually relevant to a specific situation, whether a social media post's author is credible, or whether the location attached to a posted message has a sufficient level of detail. Furthermore, the context dependency and highly subjective character of information quality notions became apparent. Therefore, it can be concluded that the “fit of information to specific tasks is more important than generic assessments of information quality” (Ludwig et al., 2015a). The credibility of social media data is one key dimension of information quality. The dissemination of false information and a varying credibility of authors frequently pose challenges for the analysis of social media messages. It is often challenging for inexperienced users to decide whether a social media message is reliable, trustworthy, and relevant.

Thus, a multi-platform service that gathers and analyzes social media data should provide more contextual information by enriching existing data. This could be determined, for instance, by measuring retweets or likes (e.g., as in Social-QAS). Based on an analysis of relevant contextual data, three deep learning models for the real-time credibility assessment of Twitter posts, all performing well during evaluation, were designed within the scope of the SMO (Kaufhold et al., 2021a). However, if the data collected via multi-platform services is not sufficiently contextual or if the information is untrustworthy (e.g., because an author lacks credibility or the location is too narrowly defined), there must be additional means to validate the (semi-)automatically processed information. This could be achieved by means of individualized reports

from the scene that broaden the knowledge base of situation awareness practices. The trustworthiness and quality of information can be increased by the implementation of preprocessed ranking and filtering of social media messages gathered across platforms as well as by the provision of advanced options for additional validation.

User-Centered Tailorability and Data Operations

Considering some SMA client applications (particularly SMO and Social-QAS), it also became apparent that a completely automated processing of big social media would not be sufficient to fulfill the end-user requirement of tailorability. Due to the subjective character of situational assessment, the SMA must possess a tailorability that allows the selection of relevant source platforms and quality assessment criteria. As a consequence, factors such as experience, personal feelings, and the situation itself have an impact on the information requirements. When gathering or analyzing information and developing information systems to support these tasks, one key question always arises: how can information systems be designed that, on the one hand, allow for automatic selection of relevant data and, on the other hand, give end users the freedom to customize this automation to enable a tailorable quality and relevance assessment in accordance with their requirements? This becomes even more important when application scenarios and work contexts vary and user practices evolve with time. Thus, concepts such as Social-QAS can facilitate the articulation of end users' requirements (Reuter et al., 2015b).

Providing suitable service endpoints with adequate filter parameters that remain consistent across heterogeneous social media is one major challenge. To some extent, the provided APIs determine the flexibility of filtering: whereas filtering by location (YouTube, Twitter) or time (YouTube, Twitter, Facebook) is supported by some social media APIs, this must be implemented manually for other platforms. Furthermore, social media platform APIs are subject to permanent development and a steady adaptation to changes is needed. Whereas minor and early announced changes, such as the temporary need for a Google+ account when using YouTube, can be accommodated more easily, others exert a significant influence on implementation. Major issues occurred due to Facebook's removal of the public post search (2015), which severely limited access to public data, as well as the shutdown of the Google+ service and YouTube's reduction of API request quota (2019). The progressively growing restrictions of researchers' data access are a constant challenge for developing and maintaining multi-platform social media services and were thus also labeled as an "APIcalypse" (Bruns, 2019).

Conclusion

Without doubt, social media are of great significance and interest to various stakeholders involved in emergencies, including official emergency services and communities of voluntary helpers. This chapter discusses the challenges and opportunities for utilizing big social data in emergencies and presents the development of an extensible

Table 3 Summary of the identified challenges for multi-platform social media services in emergencies

ID	Challenge	Description
C1	Specification	Most, yet not all, social media metadata can be stored in accordance with an interoperable specification, e.g., Activity Streams 2.0
C2	Comparability	The extraction or computation of metadata is sometimes necessary for cross-platform comparisons of (big) social data
C3	Classification	The creation of social media classifiers is time-consuming despite the time-critical constraints of emergencies, and classifiers must perform well on multi-platform datasets
C4	Interpretability	Interpretations of evaluative metadata, e.g., trustworthiness and information quality, are context-dependent and highly individual
C5	Tailorability	To address end users' objectives, the gathering of social data requires sufficient filter parameters (e.g., by location or time), which sometimes require a downstream implementation
C6	Queryability	Official social media APIs support a variety of logical query operators (e.g., AND, OR, and NOT), and the emulation of such operators often results in a high quota consumption
C7	Adjustability	Frequent modifications of official social media APIs, e.g., the Facebook or Instagram API, require corresponding adjustments or can cause the loss of data access

and standardized social media API (SMA), which supports the gathering, processing, and retrieval of acquired data from multiple social media platforms. The SMA has been deployed and evaluated in three scenarios to assist volunteers across social media (XHELP), facilitate the tailored quality assessment of social data (Social-QAS), combine social media with movements of volunteers for emergency services (CrowdMonitor), manage the tasks of spontaneous volunteers through public displays (City-Share), create social media alerts for emergency services (ESI), and filter for credible and relevant social data (SMO). Although the challenges for such multi-platform services are mostly determined by the research goals, client applications, and use cases, Table 3 outlines some of the challenges encountered in the evaluations.

Abstract

Management of the distribution of emergency resources is a key requirement in the midst of any disaster. This task is especially challenging because of the lack of relevant firsthand information in real time. From discussions with professionals engaged in post-disaster relief operations, we understand that two specific categories of knowledge are crucial in a post-disaster situation – (i) resource-needs, i.e., what resources are required, and (ii) resource availabilities, i.e., what resources are available in the disaster-affected region or potentially available from elsewhere. The key question is how to get such information in real time in a post-disaster scenario. Online social media are renowned repositories of vital real-time information during disasters. Nevertheless, reliable and automated methods are needed to extract this important information which is usually hidden

amid thousands of conversational posts. We have developed natural language processing-based methods for automatically identifying social media posts that inform about resource needs and resource availabilities and for understanding the semantics of such posts. We have also developed a method for matching resource needs with the resource availabilities that can potentially fulfill the needs. This chapter summarizes the methods we have developed for identifying and matching resource needs and resource availabilities from social media during post-disaster situations.

Disaster · Online social media · Twitter · Resource management · Natural language processing · Neural models

Introduction

Due to the ubiquity of smartphones and handheld devices across the globe and availability of Internet connectivity during most of the disasters, relief workers as well as the affected population nowadays make frequent use of online social media (OSM) during disaster situations. Several recent studies have proven that OSM provides firsthand information from the affected population in real time during any mass emergency (Imran et al., 2015; Nazer et al., 2017; Li et al., 2017; Alam et al., 2018; Ghosh et al., 2018; Reuter et al., 2018, 2019). However, in OSM, often the presence of misinformation and conversational contents like prayer or sympathy for affected population and victims are more prevalent than the critical situation information. Thus, several studies focused on extracting various trustworthy critical information from the OSM, such as identification of situational information (Rudra et al., 2015, 2018; Zade et al., 2018), location extraction and tracking from social media posts during emergencies (Karimzadeh et al., 2013; Lingad et al., 2013; Paule et al., 2018), detection of rumors and fake news from social media posts (Mondal et al., 2018; Wang & Zhuang, 2018), detection of important events and event-specific actionable tweets from OSM during a disaster (Hasan et al., 2018; Laylavi et al., 2017), and use of social media in the diffusion of critical information during mass emergency (Kim et al., 2018). Social media has been shown to be useful in disseminating disaster information among the volunteers (Abedin & Babar, 2018) as well as in reaffirming the roles of various stakeholders (Liu & Xu, 2018).

In this chapter, we focus on utilizing OSM for post-disaster resource management during the relief operation. To ensure efficient management of resources using social media posts during a relief operation, we consider three related research problems in this chapter – (1) identifying social media posts informing about needs of resources or availability of resource, (2) understanding the posts that inform about need or availability of resources, and (3) matching the posts informing about resource needs with posts that inform about appropriate resource availability.

For the first problem of identifying resource need posts and resource availability posts, we experimented with unsupervised retrieval and pattern matching methods,

as well as supervised classification methods. For the second problem, we developed a natural language processing-based methodology to understand the semantics of resource need and resource availability posts. Finally, we developed a method for matching resource need posts with resource availability posts, considering both resource similarity and geographical distance between where the resource is needed and where it is available. We applied our proposed methods to tweets posted during several real-world disasters (e.g., an earthquake in Nepal, an earthquake in Italy, and floods in the city of Chennai, India) and observed that our methods work satisfactorily on such real-world data. We describe these works briefly in this chapter; further details are available in our prior works (Basu et al., 2018, 2019; Dutt et al., 2019).

Utilizing Social Media for Post-Disaster Resource Management: Opportunities and Challenges

When a natural disaster strikes, to save human life, the rational and efficient distribution of the emergency resources in real time becomes utmost priority. According to the World Disaster Report 2018, however, critical resources are *not* reaching millions of victims of natural disasters. To understand the challenges faced by responding authorities in distributing resources in the aftermath of a disaster, we consulted NGOs such as SPADE (<http://www.spadeindia.org/>) and Doctors For You (<http://doctorsforyou.org/>) who work in disaster-prone areas on a regular basis. The NGOs pointed out *the lack of real-time information on the need and availability of resources* as the major reason behind the fact that resources are frequently dispersed on an ad hoc basis without understanding how much resource is actually necessary or where it is needed. Hence the key question is from where such real-time information can be obtained.

Online social media (OSM), such as Facebook, WhatsApp, and especially microblogging sites like Twitter and Weibo, have been demonstrated to be repositories of critical real-time information during disasters (Imran et al., 2015; Li et al., 2017). Hence it is natural to investigate if such information (as stated above) can be extracted from OSM. There are three key challenges in effectively using social media posts (e.g., tweets) for post-disaster resource management. We briefly describe these challenges here.

- (1) **Identifying social media posts informing about needs of resources or availability of resources** – the main challenge is that such critical information is often hidden among thousands of conversational/opinion posts. Hence automated methodologies are needed to identify posts containing these critical information.
- (2) **Understanding the need or availability of resources** – it is essential to understand the posts that inform about need/availability of resource. Specifically, it is necessary to extract some important information from these posts, such as the particular resource name, the quantity that is needed/available, the location where the resource is needed/available, and so on. It is challenging to extract

such information, since social media posts (especially tweets) are often written informally, without obeying the rules of natural languages. Hence traditional natural language processing and information extraction methods often do not perform well on such posts.

- (3) **Matching resource needs with appropriate resource availabilities** – once the needs and availabilities are identified, the next challenge is to match the need for a particular resource with an availability of the same resource. It must be noted that, during a post-disaster scenario, resources may be available at some selected places (e.g., prominent locations that are close to an airport/rail station), whereas resources may be needed at many distinct places. Also, need locations (where resources are needed) may be at different distances from availability locations (where resources are available). If an availability location is far away from a need location, it may take several days to transport relief material. However, during disasters, urgent requirement of critical resources like medicines, food, and water must be catered quickly. Thus the matching of resource needs with resource availabilities should consider both the similarity between the resource needed/available and the geographical proximity between the location where a resource is needed and the location where the resource is available.

We have developed methodologies to address the challenges mentioned. We have specifically focused on Twitter due to the ease of data collection and the real-time nature of Twitter conversations. Our works are summarized in the rest of this chapter.

Identifying Social Media Posts Informing About Needs of Resources or Availability of Resources

The first step in managing relief activities during a disaster is to determine what resources are required and available in the affected region. To this end, we developed methods to detect the two categories of tweets – **(1) need tweets** that include information regarding the requirement of various critical resources, such as food, tent, medicine and medical resources, etc., and **(2) availability tweets** that report the availability of such resources.

Dataset. In most of our works, we applied our methods over tweets that were posted following two earthquake events – (i) the Nepal earthquake in 2015 (https://en.wikipedia.org/wiki/April_2015_Nepal_earthquake) and (ii) the Italy earthquake in 2016 (https://en.wikipedia.org/wiki/August_2016_Central_Italy_earthquake). The Twitter Search API (<https://dev.twitter.com/rest/public/search>) was used to collect English tweets posted during the 7-day period immediately after each event. Then human annotators were appointed for identifying all need tweets and availability tweets from the datasets (which comprised of the gold standard). Some sample need tweets and availability tweets that were posted during the Nepal earthquake are reported in Table 1. Further details of these datasets are available in our prior works (Basu et al., 2018, 2019; Dutt et al., 2019).

Table 1 Examples of need tweets and availability tweets posted after the earthquake in Nepal in 2015 (from one of our datasets). Each need tweet is shown alongside a matching availability tweet, and the matching resource(s) in the two tweets are highlighted in bold

Need tweet	Availability tweet
Lack of electricity and drinking water aggravating problems for the locals specially for Earthquake Victim	@AmeriCares We would like to offer solar powered 500 l and up water filtration systems
Chirayu hospital has been evacuated after cracks after #NepalQuake, ishan hospital treating patients on the road	Four planes to leave for #Nepal tmrw carry meds, med team, 30-Bed Hospital , rescue experts, dry food, tents
People are searching for tent , at BICC area. No foods, no water	#ArtofLiving Nepal Centre providing shelter to hundreds of ppl. Volunteers providing food and water

Methods. We conducted an extensive analysis of two types of methods for detecting OSM posts that report about resource requirement/availability during an ongoing disaster event – (i) unsupervised pattern matching and retrieval methods and (ii) supervised classification methods.

(1) **Unsupervised pattern matching and retrieval methods:** During an ongoing disaster, preparation of ground truth in real time often becomes expensive. Thus, unsupervised methodologies are preferred in such situations as labeled training data is not required. We considered two pattern matching techniques – (i) Purohit et al. (2013) presented a set of regular expressions to identify tweets indicating donation requests/offers of different resources, and (ii) Temnikova et al. (2015) provided a large number of patterns (EMTerms) to match various categories of critical information contained in tweets posted during a disaster situation. We utilized these patterns to identify need/availability of resources; details are available in Basu et al. (2019).

We also employed language model-based information retrieval (search) methodologies. We also experimented with a variety of neural network-based models, such as models using word-level embeddings (e.g., Word2vec (Mikolov et al., 2013)), models that incorporate both word-level and character-level embeddings (Chen et al., 2015), and models that employ a combination of such embeddings with attention (Cao & Rei, 2016). We also proposed two models combining word-level and character-level embeddings – details are available in our prior work (Basu et al., 2019). These IR methods start with a base query for preliminary retrieval (e.g., the terms “need” and “require” are used to construct the base query for need tweets) and then perform *query expansion* for the final retrieval.

(2) **Classification methods:** We employed an assorted set of classical and deep learning classifiers to categorize tweets into three classes: need tweets, availability tweets, and other tweets (the class containing tweets that are neither identified as need tweets nor identified as availability tweets by the annotators). Traditional classifiers like gradient-boosted decision trees (GBDT), support

vector machines (SVM), and naive Bayes (NB) were used, along with neural classifiers such as convolutional neural networks (CNNs); details are available in Basu et al. (2019). Since it is impractical to label large amounts of training data during an ongoing disaster, the only practical option is to train models on data collected during past disasters. Thus, we employed classifiers in *cross-domain* settings, i.e., classifiers were trained on a dataset of tweets related to a preceding disaster event and then applied on tweets related to the ongoing (unseen) disaster event.

Comparing performance of various methods. We used standard metrics such as precision, recall, and F-score to compare the performance of various methodologies. Among unsupervised methods, pattern matching methods achieved high recall but very low precision, thus resulting in low F-scores. The retrieval methods achieved reasonable results. Among supervised methods, CNN-based methods were found to perform better than other classifiers in most cases.

Our experiments led to the following practically useful insight. The quality of data used to train classifier models has a substantial impact on the performance of the model. Supervised classifiers should be preferred for recognizing need tweets and availability tweets, if adequate training data from a similar disaster event is available. On the other hand, unsupervised retrieval strategies may be favored if there is a scarcity of high-quality training data from previous disasters.

Understanding Social Media Posts That Inform About Need or Availability of Resources

Once the need tweets/availability tweets have been identified, the next important task is to automatically understand these tweets and to extract some critical information from such tweets that would later help to match resource needs with resource availabilities.

According to the recommendations of the humanitarian aid workers with whom we discussed, we focused to extract five specific information from a given need tweet/availability tweet – (i) the specific *resource* that is required/available, (ii) the *quantity* of resource required/available, (iii) the *location* of resource need or resource availability, (iv) the *source* of the resource offerings, and (v) *contact* details (e.g., email, phone number) of the source or the victim requiring the resource. We developed an unsupervised approach in order to obtain these five kinds of information from a need/availability tweet. Our method, detailed in Dutt et al. (2019), does *not* require labeled data for training (which is difficult to obtain during an ongoing disaster).

Standard preprocessing techniques were employed on the tweet texts to remove URLs, mentions, emoji brackets, “RT” (retweet marker), and non-ASCII characters (such as “#,” “&,” ellipses, etc.). Next, CamelCase words and combined alphanumeric phrases were also split into separate terms (e.g., “Nepal2015” was split into

“Nepal” and “2015”). Then the five types of information stated above were extracted as follows.

Extracting resources. The algorithm performs *dependency parsing* on the pre-processed tweet text to construct a dependency tree for a tweet. From this dependency tree, some specific words were identified as *head words*, e.g., terms frequently used to express need (e.g., “require,” “need”) and availability (e.g., “available,” “distribute,” “donate”). Then the dependencies of the child nodes of these head words were observed. As resources are mostly nouns, only those words that had been tagged by a part-of-speech (POS) tagger as a common/proper noun were considered as *possible* resources. Next, these possible resources were compared to a list of resources designated by the United Nations Office for the Coordination of Humanitarian Affairs (UNOCHA) as being often required in disaster situations, and the matching words/phrases are finally identified as resources.

Extracting geographical locations. An unsupervised methodology was adopted for detecting location inference from tweet text. The steps of the algorithm are as follows – (i) a statistical word segmentation algorithm (Norvig, 2009) is used for hashtag segmentation, (ii) proper nouns were identified using a POS (part-of-speech) tagger and a list of common suffixes of location names (e.g., “street,” “city,” “NW,” “SE”) were utilized to recognize potential locations from among these nouns, (iii) regular expression match is used to recognize phrases that encompass one of some common suffixes or prefixes of locations (e.g., “street,” “avenue”), (iv) dependency parsing of need tweets and availabilities is employed. Noun phrases were extracted from the dependency graph, and then a named-entity recognition (NER) tagger was used to identify potential locations. (v) Finally, among the extracted list of potential locations, those which correspond to real-world locations were retained using a gazetteer (OpenStreetMap) (<https://geocoder.readthedocs.io/providers/OpenStreetMap.html>). For further details of the algorithm, readers are requested to refer to our work (Dutt et al., 2019).

Extracting quantities. The method examined if the resource names (already identified, as described above) are prefixed by a numeric token in the tweet text. In addition to checking for numeric tokens, we also checked if such a token corresponds to a real number orthographically (e.g., “5000”) or semantically (e.g., “100”). If a token of any of these types is found to precede a resource name, that token is identified as a quantity.

Extracting sources. As stated earlier, we constructed a dependency tree for a tweet. From this tree, subjects of the corresponding head words which were also tagged as proper nouns were extracted. Note that proper nouns corresponding to locations, persons, and organizations had already been identified from the tweet text. The words which had been identified as resources or locations were filtered out, and the rest are identified as viable sources. As an example, from the tweet text “ArtofLiving distributes food for 1000 victim at Kathmandu,” the algorithm identified “food” as a resource using the steps described above. Since “ArtofLiving” is tagged as a proper noun and is a nominal subject (nsubj) to the verb “distribute,” it was then identified as a source.

Extracting contact. We applied common regular expressions on preprocessed tweet text to identify email IDs and phone numbers as contact information.

Performance evaluation of the above method. We considered 50 need tweets and 50 availability tweets that were randomly selected from the two datasets described in section “[Identifying Social Media Posts Informing About Needs of Resources or Availability of Resources](#).” Thus, 200 tweets were randomly selected from the two datasets combined, 100 being need tweets and 100 being availability tweets. Next, the five aforementioned important fields were extracted by the proposed algorithm from each of the selected tweets. The same tweets were also given to human annotators, to identify the same pieces of information. The information extracted by the human annotators comprises of the gold standard. Comparing the gold standard with the information extracted by the algorithm, we computed (i) precision, (ii) recall, and (iii) F-score, separately for each of the five fields.

We observed that our approach is capable of extracting the five categories of information with reasonably high precision and recall. In extraction of resource, location, and contact fields, our proposed approach achieved F-score values greater than 0.8 for both Nepal-quake and Italy-quake datasets. Our method also worked fairly well at retrieving source and quantity information with F-score value greater than 0.7. Further details are available in our previous study (Dutt et al., [2019](#)).

Matching Resource Needs with Appropriate Availabilities

We presume that the methods discussed in section “[Identifying Social Media Posts Informing About Needs of Resources or Availability of Resources](#)” have been used to identify a set of need tweets and availability tweets. Then the important fields in these tweets have been identified by employing the method discussed in section “[Understanding Social Media Posts That Inform About Need or Availability of Resources](#).” Now, the challenge is to match a need tweet with appropriate availability tweets from among the ones identified. A few examples of need tweets and matching availability tweets have been given in Table 1.

The few previous studies that attempted to match resource needs with resource availabilities solely looked at the resources (Purohit et al., [2013](#)), with no attempt to comprehend other characteristics of need tweets and availability tweets that are important for realistic matching. In contrast, we utilized some of the specific information that are extracted from need tweets and availability tweets using the methodology depicted in section “[Understanding Social Media Posts That Inform About Need or Availability of Resources](#).” We proposed two techniques for matching needs with availabilities based on the extracted data: one that considers only resources and the other that takes into account both resources and the proximity of the location where the resource is needed (need location) and the location where the resource is available (availability location). We briefly describe these methods below.

Matching algorithms considering resource similarity. We propose two categories of algorithm based on resource similarity.

- (i) *Matching based on resource names:* We identify if there are common resource names mentioned in a need tweet and an availability tweet. We observe what fraction of the resources mentioned in a need tweet is also mentioned in an availability tweet.
- (ii) *Matching based on resource embeddings:* Typically, different tweets may refer to semantically similar resources but use different terminology (e.g., the need for “shelter” and the availability of “tents”). We employed word embeddings to find such matches because it can capture the semantic context of terms. To this end, we proposed two different models; the first model uses the local Word2vec (Mikolov et al., 2013) embeddings learned over the collection of tweets relevant to the present disaster (e.g., the Nepal-quake and Italy-quake datasets), and the second model employed Word2vec embeddings pretrained over tweets posted during a large number of past disaster events (provided by Imran et al. 2014).

Matching based on resources and location proximity. We proposed a method for matching tweets that considered both the resources and the geographical locations specified in the tweets. Given a specific need tweet and an availability tweet (both of which mention resources and locations), resources and locations were extracted from both using the methodology described in section “[Understanding Social Media Posts That Inform About Need or Availability of Resources](#).” Then the following similarity scores between the two tweets were computed.

Resource similarity score. We utilized the cosine similarity of the resource vectors generated from the two tweets using pretrained Word2vec embeddings, to determine the level of similarity between the two resources referenced in the tweets.

Proximity score. The distance between a need location (obtained from a need tweet) and an availability location (obtained from an availability tweet) was computed from the geographical coordinates of the two locations. A bounding box around the country/city where the incident happened was used to normalize the distance and thus get a proximity score.

The final matching score between a need tweet and an availability tweet is calculated as a weighted sum of the resource similarity score and the proximity-score. The two scores are given equal weighting of 0.5.

Performance evaluation. Each matching method (as described above) generates a ranked list of availability tweets for a particular need tweet. We used each matching method to find five top-matching availability tweets for each need tweet. These matching need-availability tweet pairs are examined by human annotators to ascertain if the matchings are appropriate, i.e., if both tweets mention the same resources and if the availability location is sufficiently close to the need location. The following evaluation metrics are then used to assess a matching method – (i) *precision of matching*, the fraction of tweet pairs that are accurately matched (according to the human evaluators) by a matching methodology is called precision. Essentially, we calculated Precision@5 (since we considered five top-matching availability tweets for a particular need tweet). (ii) *Recall of matching*, the percentage of all need tweets for which a method is able to locate at least one accurate match (based on the annotators’ judgment) is called recall. (iii) *F-score of matching*, finally, a matching method’s F-score is the harmonic mean of recall and precision.

Table 2 Performance of methods for matching need tweets and availability tweets. Results reported here are over the dataset related to tweets posted during the 2015 Nepal earthquake. (Reproduced from our prior work (Dutt et al., 2019)). Highest values marked in boldface

Need-availability matching method	Precision	Recall	F-score
Based on common resource names	0.79	0.92	0.85
Based on local embeddings of resources	0.75	0.88	0.81
Based on pretrained embeddings of resources	0.84	0.96	0.89
Based on pretrained embeddings of resources and location proximity	0.73	0.91	0.81

Table 2 reports the result of several matching methods for the Nepal-quake dataset. It can be observed that our proposed methods for resource-based matching attain a precision of more than 80% and recall of higher than 95%, outperforming baseline methods by a significant margin (details are available in our prior work (Dutt et al., 2019)). Our proposed matching method that takes into account both resources and geographical proximity is also quite effective. This algorithm can identify availabilities that are geographically close to the location of the need for more than 90% of need tweets that include a location.

Note that the evaluated result of the matching method based on pretrained resource embeddings only (F-score 0.89) is slightly higher than that of the method based on both resource embeddings and location (F-score 0.81). Since we considered a threshold for the distance between the location of demand and the availability (e.g., 100 km), some matches in terms of location and resources were not deemed to be correct in the final evaluation if the distance between the two locations was higher than this threshold.

To our knowledge, the Dutt et al. (2019) study was the first effort to build techniques for matching resource needs with available resources, while taking into consideration critical factors like geographical proximity (which was not taken into account in previous studies).

Conclusion

Management of the allocation of emergency resources from where they are offered to where they are needed is a vital requirement in the midst of any disaster. Given the shortage of resources during a disaster, this distribution must be done in a sensible and efficient manner. Because there is a dearth of real-time knowledge on resource needs and availability, this task is extremely challenging. In this chapter, we look at social media services (particularly, the Twitter microblogging site) as potential sources of real-time information in the aftermath of a disaster. Various techniques are presented to develop a holistic framework for resource distribution in a post-disaster scenario.

Future directions. There are several possible future directions of research extending the works described in this chapter. We briefly mention a few possible extensions.

-
- (i) The methods for identification and matching of resource need with resource availabilities described in this chapter consider only tweets in English. However, it has been observed that during disaster events in various parts of the world, a lot of information is also posted in local/regional languages (such as Hindi in case of disasters occurring in the Indian subcontinent) (Rudra et al., 2018; Basu et al., 2017). Hence the methods can be adapted to handle tweets in both English and local/regional languages, as well as code-mixed tweets (in which many languages are utilized in the same tweet).
 - (ii) The works in this chapter consider information collected from one social media (Twitter) only. However, when a disaster strikes, information is scarce and critical; hence, for a comprehensive analysis of the situation, responding authorities frequently need to identify resource needs and resource availabilities by integrating data from multiple social media channels such as Twitter, Facebook, WhatsApp, Telegram, etc. There are several challenges in analyzing such heterogeneous data sources simultaneously, which should be explored.

Any attempt toward developing a comprehensive framework for utilizing social media for post-disaster resource management should explore these challenges in the future.

Abstract

Reliance on social media has become quite prevalent to initiate and assist rescue operations for humanitarian organizations. Their information needs vary greatly, from a general summary to specific needs (e.g., infrastructure damage, missing people, and injured or dead individuals). These humanitarian classes also contain several small-scale subevents that cover information from diverse dimensions. Recent methods tried to identify subevents as an event-action pair from tweets. Further, such subevents are jointly optimized with informative words, humanitarian classes using an integer linear programming framework to generate the summaries. This chapter covers the details about such subevent detection and summarization strategies. Extensive evaluation over three diverse disaster events shows that such strategy performs 6–30% better than the state-of-the-art approaches. The entire subevent and summarization framework is optimized to generate summaries in near real time.

Keywords

Humanitarian categories · Subevent identification · Summarization

Introduction

Volunteers and crisis responders can use information reported by people on the ground via social media to get an overall idea of the situation. However, they would prefer summaries of tweets due to information overload (Imran et al., 2015). Furthermore, the need of different stakeholders varies a lot. Some are looking for a generic report for a particular day (**high-level information need**). In contrast, others look for class-specific updates (e.g., “**infrastructure damage**,” “**missing person**”) or personal updates about missing family members.

In general, the information posted during a crisis event is scattered into different humanitarian classes/categories such as “infrastructure damage,” “injured or dead people,” “shelter service,” “volunteer and donation supplies,” etc. Imran et al. (2014) proposed a classification system AIDR that can classify the tweets into aforementioned classes. Further, to get a concise view of the situation, summarization of the tweets is one of the requirements of the agencies. Crisis-related summarization algorithms portray a general view of the situation (Kedzie et al., 2015; Rudra et al., 2015, 2016; Nguyen et al., 2015). However, in most of the cases, it does not address the multidimensional information needs of different stakeholders such as field experts, NGO agencies, rescue workers, etc.

A long-ranging natural disaster such as earthquake, flood, typhoon, cyclone, etc., consists of many small-scale subevents containing updates like “toppling of buildings,” “shutdown of airport,” “dispatching of medical aid,” etc. Apart from information summarization, identification of such subevents is also necessary for the responders. Such subevents are basically event-action pairs that help agencies to detect actionable information, and based on that they can initiate rescue operations

on ground. These subevents are also helpful to boost the performance of the summary and make the summaries more comprehensive.

In some classes (e.g., “missing people,” “injured or dead”), the information frequently gets updated. For example, at time instant t_1 , there are reports of x injured people, but at $t_1 + \epsilon$ there are updates about more than x injured people (Rudra et al., 2015). Hence, the additional challenge is to make the summaries factually consistent over time. Along with that, explainability of the models is also a crucial factor. This provides a real hindrance in the deployment of the models in real-life applications. In recent times, interpretability of the models gain a lot of attention (Zhang et al., 2021). This is really useful in the automated decision process such as *dispatch of relief material*.

So far, existing approaches deal the subevent detection problem through the lens of topic discovery (Blei et al., 2003; Yan et al., 2013). However, such approaches have significant limitation in terms of comprehensibility. Recent approaches (Badgett & Huang, 2016; Rudra et al., 2018b) focused on the pos-tag information of the words and the dependency relations among them. Subsequently, these short snippets are also used to improve the quality of the summary by jointly optimizing them along with the informative words. Such strategies are able to boost the summarization performance by 6–30% in terms of ROUGE-1 F-score. In this chapter, such methods are covered in detail.

The organization of the chapter is as follows. An overview of existing approaches and comparison of the trade-offs of different strategies are reported in section “[Related Work](#).” Finally, we select one of the recent methods and elaborate its functionality in next sections. Section “[Dataset and Humanitarian Category Identification](#)” provides the data statistics. The method details are explained in sections “[Sub-Event Detection](#)” and “[Summarization Algorithm](#).” Performance of the selected approach is highlighted in sections “[Evaluation of DEPSUB](#)” and “[Evaluation of SCC](#).” Finally, section “[Conclusion and Future Directions](#)” concludes this chapter with some future directions.

Related Work

Vulnerable communities post real-time updates in the aftermath of a disaster (Sakaki et al., 2010; Varga et al., 2013). This information is a useful resource for disaster responders and NGOs (Imran et al., 2015; Castillo, 2016).

Subevent detection during crises: Several approaches extract subevents from crisis-related tweets (Abhik & Toshniwal, 2013; Pohl et al., 2012). Recent methods tried to detect subevents/topics from tweet streams evolving during disasters (Meladianos et al., 2015). Most existing methods tried to form clusters from the tweets using different approaches (latent dirichlet allocation (Blei et al., 2003), self-organizing map (Pohl et al., 2012), and biterm topic modeling (Yan et al., 2013), etc.), and further, some highly frequent words from each cluster are chosen as subevents or topics.

End users find it difficult to comprehend a bag of words as a representative topic. For example, a topic is represented by traditional biterm topic models using most probable terms such as “relief,” “material,” “to,” “Nepal,” “NDRF,” etc. However, if the subevents can be identified in a more structured way such as “building topple,” “people strand,” “medicine supply,” etc., it will provide useful information for the responders. They can easily understand and operationalize their resources. We tried to avoid bag-of-words and clustering-based subevent identification strategies and designed more meaningful, user-friendly, and comprehensible subevent detection strategies that rely on noun-verb pairs that are useful in disaster scenarios. For example, a subevent like “building topple” is easy to understand than a collection of words such as “building, work, field, topple,” and users could easily understand that it is related to the destruction of buildings based on the immediate context.

Recently, Badgett and Huang (2016) proposed a dependency parser-based strategy to detect subevents from news articles that rely on sentential cues. This method also explores the dependency relations present in a sentence. However, their strategy, designed for formal text, is not able to capture dependencies from noisy tweet texts. Additionally, their method works in an iterative fashion, i.e., it starts with a small set of sentences and adds new sentences that contain subevents to the existing set in an incremental fashion. The iteration continues until the convergence of the method and may have a severe impact on the running time. Hence, for large datasets, this method fails to produce output in real time. Recent approaches also extend this idea toward tweets and develop methods to detect meaningful subevents from crisis-related tweets (Rudra et al., 2018b; Arachie et al., 2020; Chen et al., 2018). Specifically, Belcastro et al. (2021) developed a subevent detection approach, SEDOM-DD, to identify the subevents and their associated areas.

Tweet summarization: The evolving nature of Twitter makes the summarization method more difficult compared to standard static document summarization. Researchers tried to incorporate important situational updates from tweets to generate summaries to generate crisis-related summaries. Some of these approaches focus on topic detection, pagerank-based strategies (Nguyen et al., 2015), and multi-objective optimization (Saini et al., 2019) whereas others focus on ILP-based optimization strategies (Rudra et al., 2015, 2018a). Real-time general tweet summarization approaches are also proposed (Shou et al., 2013; Olariu, 2014). Shou et al. (2013) used clustering to find similar tweets and finally apply LexRank (Erkan & Radev, 2004) to retrieve extractive summaries. Apart from extractive methods, Rudra et al. (2016, 2019) proposed an abstractive summarization method for crisis events that build bigram-based word graphs and combine information from multiple related tweets. Kedzie et al. (2015, 2016) proposed an extractive summarization strategy over news articles that computes the saliency score of sentences using an affinity clustering-based setup. More recently, BERT-based sentence similarity strategies have been used for better representation learning and summarization (Zheng & Lapata, 2019). Li and Zhang (2021) proposed semantic terms and a graph network-based Twitter event summarization approach.

Neural approaches have shown significant improvement in both extractive and abstractive document summarization. Most of these models exploit the power of large pretrained language models (e.g., BERT, BART) and provide effective summaries for CNN/DailyMail, Gigaword, X-sum datasets (Zhang et al., 2020; Zhong et al., 2020). A major drawback of such models is the requirement for a large amount of annotated data. This hinders the application of such models toward evolutionary tweet streams. It will be an interesting direction to apply self-supervised and semisupervised learning strategies to overcome labeled data scarcity issues for tweet summarization.

Big Data Management During Crisis: Song et al. (2022) presented an overview of big data and emergency management and highlighted technologies and applications across six different categories (e.g., remote sensing, resilient communication networks, etc.). They also highlight the need for mathematical models for evacuation-oriented optimized scheduling, resource allocation optimization model, etc. Xia et al. (2019) measured spatiotemporal accessibility to emergency medical services through GPS data. Methods were also proposed to process actionable information from the incident tweet streams (McCreadie et al. 2019). Recently, TREC is also organizing the task for crisis-related fact summarization TREC (2022). Along with text, image analysis also gained a lot of attention. Disasters also cause damages to the heritage sites and buildings. Kumar et al. (2020) developed a method to detect such damages from social media images. Lots of benchmark datasets are also made available to the research community to make progress in multimodal analyses of crisis images (Alam et al., 2020, 2021a, b). Prior studies showed that actionable updates are more necessary than situational updates (Zade et al., 2018; Kropczynski et al., 2020). Coche et al. (2021) proposed a model that embeds the concept of actionable information into Endsley's model of situational awareness (Endsley, 2017). Chassera et al. (2021) extracted concept-instance relations from the disaster-related text to populate the crisis-specific ontologies. Such kind of unsupervised knowledge-based construction will be helpful for future crisis-related event summarization.

This chapter primarily covers the unsupervised subevent and summarization approach proposed in Rudra et al. (2018b). It also proposed the ideas for processing actionable information. The methods were developed based on the following observations – (i) a disaster consists of several small-scale subevents, and the final summary can be improved by including such subevents; (ii) different stakeholders have multidimensional needs such as rescue agencies, NGOs, government, etc. They proposed an approach to generate summaries at various granularities and satisfy the needs of different end users; and (iii) some updates are time critical, and it should be processed separately along with the generic summarization.

The performance of the method is evaluated for three disasters: the 2015 Nepal earthquake (1.87 M), the 2014 Typhoon Hagupit (0.49 M), and the 2014 Pakistan flood (0.25 M). The approach shows comparatively better performance over state-of-the-art subevent detection (Abhik and Toshniwal (2013), Badgett and Huang (2016), Pohl et al. (2012), Yan et al. (2013) and summarization Kedzie et al. (2015), Rudra et al. (2015, 2016), and Nguyen et al. (2015)) approaches.

Table 1 Dataset description for three disaster events. NA indicates that a specific class is absent for an event (i.e., no labeled data or very few tweets are present in the class (≤ 500))

Category	NEQuake	Hagupit	PFlood
Missing, trapped, or found people	10,751	NA	2797
Infrastructure and utilities	16,842	3517	1028
Donation or volunteering services	1530	4504	27,556
Shelter and supplies	19,006	NA	NA
Caution and advice	NA	25,838	NA
Displaced people and evacuations	NA	18,726	NA

Dataset and Humanitarian Category Identification

AIDR (Imran et al., 2014) is used to collect the disaster-related messages from Twitter posted during three major disaster events – **(1) Typhoon Hagupit (Hagupit):** Around 0.49 million tweets are collected between 6 and 8 December 2014 by searching via keywords such as “TyphoonHagupit,” “TyphoonRuby,” “Hagupit,” etc.; **(2) Nepal Earthquake (NEQuake):** Around 1.87 million tweets are collected between 25 and 27 April 2015 based on different keywords (e.g., Nepal Earthquake, NepalQuake, NepalQuakeRelief, etc.); and **(3) Pakistan Flood (PFlood):** Related tweets are collected using different keywords (e.g., pakistanflood, PakistanFlood, Pakistanflood, etc.) on September 7–8, 2014. This dataset contains around 0.24 M tweets.

Humanitarian organizations such as UNOCHA and UNICEF identified that tweets are scattered in different humanitarian categories/classes (Vieweg et al., 2014). Such classes may vary across different disasters (Castillo, 2016). AIDR (Imran et al. 2014) system is used to classify the tweets into different humanitarian classes. AIDR system was trained on manually annotated tweet sets over diverse disaster events (Imran et al., 2013, 2016). Detailed data statistics of three events are reported in Table 1.

Subevent Detection

A humanitarian class such as “infrastructure damage” contains information about subevents such as “building collapse,” “airport shut,” etc. Latent topic distribution approaches (Blei et al., 2003; Yan et al., 2013) may be used to generate such subevents, but they represent subevents as a collection of most probable words. However, domain experts at the United Nations Office for the Coordination of Humanitarian Affairs (OCHA) identified that such subevents are very generic and not that useful in decision-making process (Vieweg et al., 2014).

A thorough analysis of a few hundred tweets from web sources (Telegraph, 2015) was performed to understand the pattern of subevents. Broadly, subevents comprising of two nuggets – (a) entity (noun): the main topic/entity of an event (e.g., person,

Table 2 Popular subevents learned from the first day of the Nepal earthquake (Apr 25, 2015)

Class	Subevents
Infrastructure	“Airport shut,” “service affect,” “building collapse,” and “road crack”
Missing	“Tourist strand,” “family stuck,” and “database track”
Shelter	“Medicine carry,” “aircraft deploy,” and “emergency declare”

organization, place, etc.), (b) action-part (verb): describes the occurrence of an incident on the given entity.

Some examples of such subevents from different classes are reported in Table 2. These subevents are from the Nepal earthquake, and they represent short and important information snippets. The objective is to generate such noun-verb pairs (e.g., “family stuck”) automatically.

Identifying noun-verb pairs: Twitter POS tagger (Gimpel et al., 2011) is used to extract nouns and verbs present in each tweet. The next task is to associate the corresponding nouns and verbs which is a nontrivial task. For example, in the tweet: ANI says relief material dispatched for Nepal, both “dispatched” and “says” were marked as action verbs. The term “dispatched” is related to the noun “material,” but “says” is not associated with the corresponding noun (“material”). It is not always necessary that nouns must appear prior to or adjacent to the verbs in a tweet. Earlier, dependency grammar-based subject-verb evaluation in formal sentences is proposed by Cai et al. (2009). Such strategy is also followed to extract and make the appropriate association of a noun to a verb (Kong et al., 2014).

Ranking subevents: The number of subevents identified based on the approach proposed above is quite large. Apart from that, some of the associations are not appropriate mostly due to the noisy nature of tweets and the limitation of the dependency parser. Hence, the subevents are ranked based on different factors described below. A subevent, i.e., a noun-verb pair (e.g., “road,” “cracked”) is important if the probability of the separate occurrence of the constituent words in the pair is less. This indicates that the noun-verb pair together covers different contexts like “road cracked” in multiple places. Finally, the weight of a subevent $S(N, V)$ is computed using Szymkiewicz-Simpson coefficient (Sharma & Singh, 2016) (Eq. 1):

$$\text{Score}(S) = \frac{|X \cap Y|}{\min(|X|, |Y|)} \quad (1)$$

where X and Y indicate the set of tweets containing N and V , respectively.

However, the frequent and infrequent occurrence of subevents cannot be discriminated based on Eq. 1. Hence, a discounting factor δ (Pantel & Lin, 2002) is applied to Eq. 1 to reduce the score of infrequent events.

$$\delta(S) = \frac{|X \cap Y|}{1 + |X \cap Y|} * \frac{\min(|X|, |Y|)}{1 + \min(|X|, |Y|)} \quad (2)$$

We compute the weight of a subevent S as follows:

$$\text{Weight}(S) = \text{Score}(S) * \delta(S) \quad (3)$$

The subevents are ranked based on their weights. This DEpendency-Parser-based SUB-event detection approach is referred as **DEPSUB** (Rudra et al., 2018b).

Summarization Algorithm

The information needs of different humanitarian organizations are quite different. Summarization frameworks should be able to satisfy such a diverse set of needs. For example, some may only be interested in high-level summaries of the situation whereas others are looking for class-specific summaries. A good disaster-specific summarization strategy should contain the following components: (i) presence of highly ranked subevents for each of the classes; (ii) information about humanitarian classes; and (iii) coverage of important content words (numerals, nouns, and verbs). Prior studies showed that content words (third criterion) play a significant role in generating disaster-specific summaries (Rudra et al., 2015; Nguyen et al., 2015). All such criteria can be combined and jointly optimized using an integer linear programming (ILP) framework. The tf-idf weight (with sublinear tf scaling) (Manning, 2008) represents the importance of the content word, and Eq. 3 presents the weight of subevents.

This subevent-based category-specific content words summarization method is termed as SCC.

ILP Formulation: Following ILP, objective function (4) is used to obtain a summary of L words that returns highest scoring *tweets* as the summarization output. The ILP problem is solved using the GUROBI optimizer (Gurobi, 2018). After solving this ILP, the summary is represented by the set of *tweets* i such that $x_i = 1$. Table 3 explains the symbols used in the following equations.

$$\begin{aligned} \max & \left((1 - \beta_1 - \beta_2) \cdot \sum_{i=1}^n x_i \cdot ICL(CL(i)) \right. \\ & + \beta_1 \cdot \sum_{j=1}^m \text{Con_Weight}(j) \cdot y_j \cdot \max_{i \in TC_j} (ICL(CL(i))) \\ & \left. + \beta_2 \cdot \sum_{k=1}^p \text{Sub_Weight}(k) \cdot z_k \cdot \max_{i \in TS_k} (ICL(CL(i))) \right) \end{aligned} \quad (4)$$

The scores of the content words and subevents are normalized in the [0–1] range to represent them in same scale. A content word or subevent may be part of different information classes. Hence, the weight of the highest informative class is multiplied to the scores of content words and subevents. For example, “building” is part of both “infrastructure” and “shelter” classes. The weight of “building” gets multiplied by either infrastructure or shelter class whichever possesses higher informative score.

Table 3 Notations used in the summarization technique

Notation	Meaning
L	Required length of summary (word count)
n	Total tweets count for summarization
w, m	Count of distinct subevents and content words in the n tweets
q	Humanitarian classes considered for summarization (each tweet belongs to some class)
i, k, j, b	Represents the tweets, subevents, content words, and classes
x_i	Binary indicator for tweet i (1 for tweet i that is part of summary, otherwise 0)
y_j	Indicator variable for content word j
z_k	Indicator variable for subevent k
$\text{Length}(i)$	Word count for tweet i
$\text{Con_Weight}(j)$	tf-idf weight of content word j
$\text{Sub_Weight}(k)$	Weight of subevent k
$ICL(b)$	Class b informative score
TC_j	Set of tweets where content word j is present
S_i, C_i	Set of subevents and content words present in tweet i
TS_k	Set of tweets where subevent k is present
$CL(i)$	Class of tweet i
TCL_b	Set of tweets belonging to class b
β_1, β_2	Tuning parameter – relative weight for content word, and subevent score

The objective function 4 is optimized with respect to the following constraints (Eqs. 5, 6, 7, 8, 9, 10, and 11).

$$\sum_{i=1}^n x_i \cdot \text{Length}(i) \leq L \quad (5)$$

The objective of the length constraint (Eq. 5) is to ensure total words present in the summary should not exceed the desired user-specified length L .

$$\sum_{i \in TC_j} x_i \geq y_j, j = [1 \dots m] \quad (6)$$

$$\sum_{j \in C_i} y_j = |C_i| \times x_i, i = [1 \dots n] \quad (7)$$

The goal of Eq. 6 is to ensure the coverage of content word. If $y_j = 1$, i.e., content word j is selected in the summary, then at least one tweet covering this content word must also be selected. Equation 7 ensures that all the content words of a tweet are present in the summary if a tweet is chosen to be part of the summary.

$$\sum_{i \in TS_k} x_i \geq z_k, k = [1 \dots w] \quad (8)$$

$$\sum_{k \in S_i} z_k = |S_i| \times x_i, i = [1 \dots n] \quad (9)$$

Similar to content words, Eqs. 8 and 9 guarantee the coverage of the subevent.

$$\sum_{b=1}^q ICL(b) = 1, b = [1 \dots q] \quad (10)$$

Equation 10 ensures that the sum of weight/importance of all the classes is 1.

$$\sum_{i \in TCL_b} x_i \geq \rho, b = [1 \dots q] \text{ if } ICL_b > 0 \quad (11)$$

As the summarization involved multiple classes, representative tweets from each class should be present in the summary. Equation 11 ensures that at least ρ tweets from each class having importance > 0 are present in the summary.

Scenario-specific summarization: As mentioned in section “Introduction,” the requirements of different agencies scatter a lot. Hence, the constraints need to be adjusted accordingly in Eq. 4.

High-level summary: Equal importance is given to each class, and the minimum tweet coverage from each class (ρ) is set to value 2.

Class-based summary: To summarize information from a specific class, the weight of the desired class is set to 1 and weights of others are set to zero.

Missing person summary: It is observed that relatives of the victims post information about their missing relatives, friends, during a crisis. The missing class contains such types of updates and is hidden within other information such as helpline number, launching of tools, etc. Ground-level rescue workers look for personal information like the name, last location, contact number, etc. of the victims.

Content words (nouns, verbs, and numerals) and subevents are missing from such tweets, and “name” and “relation” of the missing person carry the most important information. It is a special case of class-specific summarization. The weight of the missing class is set to 1, and others are set to 0. Subevents have no role. Hence, β_2 is set to 0.

Tweets of this category contain personal details such as the name of the missing person, and the relation of the missing person (e.g., “brother,” “wife,” “son,” etc.), to the user who posted the tweet. An example of such a tweet is “Missing my friend **Azhar**. 23 years age. Last location Sindhupalchok. Pls help.” The proposed summarization method is customized to consider name, relation, as content words.

Experimental Setup and Results

The accurate identification of the underlying subevents (DEPSUB) plays a major role in the success of the summarization scheme (SCC). Hence, the performance of DEPSUB is evaluated before SCC. Table 1 provides details about the three datasets:

(i) Nepal Earthquake (NEQuake), (ii) Typhoon Hagupit (Hagupit), and (iii) Pakistan Flood (PFlood). The tweets are further divided by date: NEQuake (25–27, April, 2015), Hagupit (6–8, December, 2014), and PFlood (7–8, September, 2014). NEQuake and Hagupit contain 4 classes and 3 days, hence, total $3 \times 4 = 12$ instances. Similarly, PFlood contains $3(\text{class}) \times 2(\text{day}) = 6$ classes. In total, there are 30 instances.

Evaluation of DEPSUB

Automatically identified subevents are evaluated both qualitatively and quantitatively using standard metrics (e.g., accuracy).

Baseline approaches: Following NLP and cluster-based subevent detection approaches are considered as baselines.

- (a) **Two-phase approach (TWS):** Badgett and Huang (2016) proposed a subevent detection approach for news articles that relies on dependency relations. Some adjustments are applied to make it applicable to tweets.
- (b) **COS-clustering:** Abhik and Toshniwal (2013) proposed a clustering-based subevent detection approach. Twitter-specific tags are discarded using a Twitter POS tagger. Finally, the top four words having the highest frequency from each cluster represent that cluster.
- (c) **LDA-clustering:** Blei et al. (2003) proposed a latent dirichlet allocation-based topic detection approach. The top four words having the highest probability of belonging to each topic cluster represent that subevent/topic cluster.
- (d) **BTM-clustering:** Biterm topic modeling (Yan et al., 2013) approach is designed for small informal texts (e.g., tweets). Clusters of related tweets are formed, and representative terms from each cluster are chosen as topic words.
- (e) **SOM-clustering:** uses a self-organizing map (SOM)-based strategy to detect the subevents (Pohl et al., 2012).

Evaluation methodology: The utility of identified subevents is measured both qualitatively via CrowdFlower (<http://www.crowdflower.com/>. Now known as Appen) and quantitatively using the ground-truth subevents.

- (a) **Evaluation using CrowdFlower workers:** Six lists of 15 subevents, one from each competing methods, are provided to the crowd workers. DEPSUB and TWS provide top 15 subevents based on their scores. For COS and SOM, clusters are ranked based on the number of tweets they contain. Finally, for LDA and BTM the number of topics is set to 15 and the top four representative words are chosen from each cluster. The crowd workers are instructed to go through the lists and choose the best one out of the six lists for the following three questions:

(Q1) Which of the six methods is able to identify most number of relevant subevents?

Table 4 Crowdsourcing-based evaluation of subevents for proposed approach DEPSUB and baselines

Datasets	Method	Evaluation					
		(a) Fraction of instances where a method wins			(b) Fraction of users voted for a method		
		Q1	Q2	Q3	Q1	Q2	Q3
	DEPSUB	0.58	0.75	0.68	0.43	0.38	0.38
	COS	0.17	0	0.08	0.13	0.12	0.23

	LDA	0.16	0	0.08	0.13	0.12	0.15

(Q2) Which of the six methods summarizes the situation (through subevents) in disaster region well?

(Q3) Which of the six methods helps the crisis-responders most in assessing the situation in the disaster region?

Table 4 (columns [3–5]) reports the statistics showing the fraction of times a technique has won. Similarly, columns [6–8] present the fraction of user votes received by a particular method. DEPSUB performs significantly better for Q1 and Q2, i.e., crowd workers find our subevents are most useful and least irrelevant. TWS is the second best, and it shows that methods that do proper association of words (DEPSUB, TWS) could help in better understanding of the subevents.

(b) Evaluation using gold standard subevents: Apart from qualitative evaluation, performance of DEPSUB is also evaluated against the ground truth in terms of precision, recall, and F-score.

Establishing gold standard subevents: Three human volunteers independently prepared noun-verb pair-based subevents for each of the instances (6 for PFlood and 12 for both Hagupit, NEQuake). The Fleiss κ score is 0.67, and it itself depicts the

complexity of the task. Finally, subevents that were selected by at least two volunteers are included in the ground truth. Performance of DEPSUB and TWS is measured due to their similarity in the output format. Some of the identified subevents of TWS contain more than two words, but such subevents are dropped because most of them are of poor quality. This also ensures a fair comparison with DEPSUB.

Overall, DEPSUB achieves average F-score 0.75, 0.76, and 0.77, and TWS gets average F-score 0.53, 0.55, and 0.46 for NEQuake, Hagupit, and PFlood, respectively. On average, DEPSUB performs 30% better than TWS. The performance of TWS is heavily dependent on the accurate identification of dependency types (e.g., “amod,” “ccomp,” etc.), but the Stanford parser does not work well for Twitter. On the other hand, DEPSUB identifies subevents as a simple pair of entity (noun) and the action (verb) taken on that entity. However, some spurious pairs (“afternoon fly,” “terminal flee”) also get selected in the process. Twitter dependency parser is used to identify the noun-verb association, but it suffers from the noisy nature of tweets. The precision of the system gets affected by $\approx 30\%$ due to these shortcomings.

Evaluation of SCC

In this section, the performance of SCC is compared with other state-of-the-art disaster-related summarization strategies, and results are reported for different scenarios.

Establishing gold standard summaries: Altogether, there are 30 instances over three different datasets. Three volunteers independently identify 200-word summaries for each of the instances. A moderate agreement is observed in the selection process (Fleiss Kappa = 0.77). Finally, the tweets that are chosen by all the volunteers are considered for the ground truth summary of a specific instance. Next, the tweets that are selected by majority of volunteers are chosen until word limit of 200 is reached. For high-level summaries, volunteers chose tweets for each day from all the available classes, and finally the same approach is followed to generate 200-word-length summaries.

Baseline approaches: The following four state-of-the-art crisis-related summarization approaches are chosen as baselines.

1. **COWABS.** is an abstractive disaster-specific summarization approach that optimizes both tweets and paths (Rudra et al., 2016).
2. **COWTS.** is an extractive summarization approach that maximizes the coverage of content words (Rudra et al., 2015).
3. **TSum4act.** is a crisis-specific approach that relies on topic detection and pagerank-based weighting scheme (Nguyen et al., 2015).
4. **APSAL.** is an affinity-clustering-based strategy designed to summarize disaster-related news articles (Kedzie et al., 2015). In our case, this is applied over clean tweets.

Evaluation metrics: Quantitative evaluation is performed using ROUGE (Lin, 2004) metric. Specifically, ROUGE-1 F-score is chosen due to the noisy nature of tweets. System summaries are generated each of length 200 words to compare their performance with the ground-truth summaries. Different values of δ_1 and δ_2 for SCC are chosen, and the best weights are fixed based on the ROUGE score. $\delta_1 = 0.5$ and $\delta_2 = 0.5$ are the best weights for NEQuake. Weights for the Hagupit and PFlood are $\delta_1 = 0.5$, and $\delta_2 = 0.3$.

Performance Evaluation of Class-Based Summarization

The ILP method selects the tweets that comprise the extractive summary for a specific disaster class. It is important and effective to highlight a subevent in a tweet if it plays a role in selecting that tweet in the summary. Further, a qualitative analysis is also performed via CrowdFlower to judge the human comprehensibility of SCC summaries.

Evaluation using gold summaries: ROUGE-1 F-scores of SCC are reported in Table 5. It shows the scores for the five algorithms for 24 instances from all three datasets. It is evident that SCC performs better than the baseline approaches. The average improvement of SCC over COWTS, APSAL, and TSUM4act are 6%, 24%, and 30%, respectively, in terms of ROUGE-1 F-score. SCC also performs better around 20% than COWABS (Rudra et al., 2016) which is an abstractive summarization technique.

Evaluation using crowdsourcing: Apart from ROUGE-based evaluation, crowd-based qualitative evaluation is performed to judge the human understandability of the summaries generated by SCC and four baselines. The results are reported in Table 6.

Given the summaries and their topic, the following four questions are asked to the workers: **(Q1)** Which method covers most of the information? **(Q2)** Which method covers less amount of redundant information? **(Q3)** Which summary is most effective in quickly understanding and comprehending the situation? **(Q4)** Do highlighted topics help in understanding the summaries over the nonhighlighted version?

Q1. Information coverage captures the content richness of a summary. A summary is considered better in terms of information coverage if it covers more crisis-related informative sentences. It is clear from Table 6 that SCC is able to capture better information over the baselines (50% of the cases). The performance of other baseline methods varies across events; hence, there is no second-best strategy that consistently performs well.

Q2. Summary understanding tries to capture the comprehensibility aspect of the summary. Volunteers are asked whether the given summary helps them in understanding the situation and the actions that could be taken at that instant. It is observed that SCC facilitates users to get a quick grasp of the situation.

Q3. Diversity captures the redundancy aspect of the summary, i.e., the variation of information in the summary. Our proposed SCC framework tries to maximize the coverage of highly ranked content words in the summary (Eq. 4). Equation 4 considers the weight of each of the content words and subevents only once (y_j and z_k are binary indicators). We observe a significant variation in the performance of

Table 5 Summarization results (ROUGE-1 F-scores) for the proposed method (SCC) and the baselines (COWABS, COWTS, TSUM4act, and APSAL) on the same situational tweet stream for each day, for each class, and for each dataset

	TSum4act	0	0	0	NA
	APSAL	0.17	0.08	0	NA

SCC. SCC performs well in 33%, 50%, and 83% cases for NEQuake, Hagupit, and PFlood, respectively.

Q4. Necessity of subevent highlight tries to measure whether the comprehensibility of the summaries gets improved due to subevent highlighting. From Table 6, we found that a significant majority of respondents (NEQuake-83%, Hagupit-92%, and PFlood-83%) admit that highlighting subevents helps to get a quick grasp of the summary.

Discussion on performance: APSAL is a clustering-based summarization strategy that creates clusters of related tweets and selects an exemplar tweet from each cluster. This method is designed for news articles, and the importance of sentences is determined based on its position in a document, pos tag of words, probability of a word belonging to an event based on language model, etc. However, most of such features are missing for tweets. Some of the features are noisy because tweets are not written in a formal way. TSum4act also maintains a cluster of information, but it assumes equal importance for each cluster. This assumption does not always hold, and summaries could be improved by providing more importance to some clusters. SCC also performs better than the abstractive summarization method COWABS and COWTS. COWABS builds a bigram-based word graph and generates paths from the related tweets. However, bigram nodes reduce the probability of combining similar tweets. Hence, some important tweets might be dropped because such tweets cannot be combined with others to form a path. On the other hand, subevents play an important role in the summarization (section “[Sub-Event Detection](#)”), and SCC outperforms COWTS which relies only on the content words.

Effect of content words and subevents: Content words and subevents are both optimized by the SCC framework. Hence, it is important to judge the influence of individual components on the overall performance. F-scores (averaged over 3 days) of SCC are compared with those obtained in the absence of one of these components.

Table 7 Comparison of ROUGE-1 F-scores for high-level summaries of SCC and the four baseline methods

Datasets	Day	SCC	COWABS	COWTS	TSum4act	APSAL
NEQuake	25/04/2015	0.4117	0.3413	0.3662	0.3241	0.2215
	26/04/2015	0.3055	0.2087	0.2896	0.2666	0.3055
	27/04/2015	0.3853	0.3353	0.3726	0.3087	0.2866
	07/09/2014	0.4524	0.3316	0.4141	0.3014	0.2016
PFlood	08/09/2014	0.4145	0.3575	0.3085	0.2030	0.1823
	06/12/2014	0.3223	0.3204	0.3008	0.2460	0.1943
Hagupit	07/12/2014	0.4124	0.2832	0.3569	0.2492	0.2314
	08/12/2014	0.3475	0.3315	0.3002	0.2359	0.2128

Dropping of subevents reduces the F-score by 7%, 1.5%, and 3.6% for NEQuake, Hagupit, and PFlood, respectively. Similarly, dropping of content words hampers the performance by 13%, 25%, and 7% for NEQuake, Hagupit, and PFlood, respectively.

Performance Evaluation of High-Level Summary

SCC method also generates a high-level summary, and it contains the following components: (i) selected tweets, (ii) classes are mentioned from which tweet gets selected, (iii) subevents present in a tweet, and (iv) distribution of tweet classes in the summary. For example, NEQuake's high-level summary on 26 April contains 30%, 20%, 15%, and 35% tweets from infrastructure, missing, shelter, and volunteer classes, respectively. Crowdsourced experiment suggests that such metadata information helps in improving the comprehensibility of the summary.

Performance: ROUGE-1 F-scores for SCC and baselines for the three datasets over different days are reported in Table 7. SCC not only outperforms other baselines but also its performance is much better than class-based summaries (Table 5). One of the benefits of SCC is that it can proportionately select tweets from different humanitarian classes. This is ensured via Eqs. 10 and 11. On the other hand, the baseline methods take the entire data as input, but the class information is missing, and such strategies do not explore that information.

Performance of Missing Person Information

Existing class-based and high-level summarization methods do not capture such specific needs. Hence, separate ground truth is prepared and coverage of the proposed approach is measured.

Establishing gold standard summaries: This kind of information is sparse in nature. Hence, a different strategy is adopted to generate the ground truth. There is no restriction on the word limit of ground truth summary. The objective is to capture all such tweets. Ground truth summary contains the tweets that are unanimously selected by all (three) volunteers. Finally, summaries of 30, 305, and 130 words are created for 3 days (25–27 April) for the NEQuake event, respectively. For PFlood

event, summaries of 110 and 80 words are prepared for the 7 and 8 September, respectively. SCC also generates summaries of the same length as the ground truth.

Evaluation: Since such events are time critical, coverage of all such information is essential. The primary focus is on the coverage/recall score of ROUGE-1. 100%, 82%, and 87% scores are obtained for NEQuake over 3 days (25–27 April), respectively. Similarly, for PFlood, recall scores for 7 and 8 September are 81% and 83%, respectively. In some cases, the method is not able to capture some related tweets. This is because sometimes (in 25% of cases) only a relationship is mentioned, e.g., *My brother is missing*. Apart from that, spelling mistakes and the use of shorthand expressions (doughter, bro, etc.) also affect the performance of the system.

Conclusion and Future Directions

During interaction with disaster responders, NGOs reveal the need of identifying small-scale subevents and summarizing the tweets from different perspectives. Accordingly, the proposed perspective-based summarization approach can generate summaries in different scenarios. This chapter has shown three different scenarios: (a) generating summaries for individual humanitarian classes, (b) high-level summaries, and (c) missing person summarization. The proposed subevent detection algorithm DEPSUB is able to identify more relevant and useful subevents. Further, such subevents help to identify important tweets in the summaries generated by SCC. It increases the diversity and understandability of the summaries. SCC performs better than the other summarization baselines by 6–30%. The importance of different humanitarian classes also varies over days. For example, infrastructure damage is more prevalent in the first couple of days whereas shelter- and volunteer-related updates become essential afterward. The proposed approach SCC can capture this and make the necessary adjustments to address those needs.

Future Direction: There are three open directions as follows:

- (i) Existing crisis-related subevent detection and summarization methods do not consider geographical information in the framework. However, spatial updates are also important along with the temporal direction. It will be useful to develop spatially aware subevent detection and summarization methods.
- (ii) Interpretability and fairness are other important aspects of model development. Existing crisis-related subevent detectors, humanitarian classifiers, and summarizers do not consider such aspects. As a disaster covers information from heterogeneous sources and multiple classes, it is important to ensure that all kinds of information get a fair representation in the final level of output.
- (iii) The actionability nature of the tweets is more important than normal situational updates. It helps responders and rescue agencies to take prompt actions based on the current requirements. Identifying and ranking actionable information is an important task.

information needs of crisis managers. In examining research on mobile phones, the chapter reveals the pivotal role they play in helping people participate in more conversations that can increase their chances for receiving help and for providing early alerts. But during disasters, power goes out and Internet connections can be lost, revealing fragile infrastructure and inequities, and underpinning current disaster communication. Mobile phones also provide a primary avenue to access social media, an important communication channel for people to share their calls for help. The chapter discusses the vast quantity of data generated by social media and how scholars are using textual, visual, geo-referenced, and network data to train machines to provide meaningful situation awareness for crisis managers. As AI-infused information technologies are being developed, often by incorporating human expertise, they are making progress toward being an integral partner in disaster response and recovery. The future of research on using ICTs to bridge some of the existing gaps includes considering additional methods, expanding to consider cultural variables, and including disaster practitioners on even broader interdisciplinary research teams.

Mobile phone · Social media · Artificial intelligence · Communication · Disaster rescue

Introduction

During disaster response and recovery, it is common for people to need help. Whether they need to be rescued, lack basic supplies to recover, or have lost property, the past two decades have seen a serious rise in the role information and communication technologies (ICTs) play in and around disasters such as earthquakes (Bean et al., 2021b; Chaoxu et al., 2019; Meier, 2012), hurricanes (Imran et al., 2020; Nieves-Pizarro et al., 2019), floods (Stephens et al., 2020), tornados (Imran et al., 2013), and fires (Meier, 2012). Furthermore, the increased accessibility of various ICTs has been linked to saving lives (e.g., Meier, 2012; Toya & Skidmore, 2015) as well as helping in thousands of rescues (Stephens et al., 2020). ICTs are also facilitating increased volunteer efforts around coordinating and providing help (Hughes, 2019; Palen & Hughes, 2018; Smith et al., 2021). Simply put, ICTs have become lifelines during disasters.

This chapter hones in on these technologies by focusing on mobile devices, social media, and the use of artificial intelligence (AI) in the form of AI-infused information technologies, and it describes what these technologies offer for crisis managers. The first part of the chapter examines why mobile phones have the potential to positively influence disaster response and recovery. It also discusses the challenges and gaps faced when mobile phones cannot be used due to infrastructure failure and digital divide issues that still marginalize many people. Next, the connection between mobile phones and social media is explained now that myriad forms of

data can be generated by social media. The chapter also compares concepts similar to one another that include humans in the loop when helping identify meaningful data. Finally, the chapter elaborates on the rise of using AI-infused information technologies to process more data and begin to assist emergency responders and disaster managers and discusses privacy concerns. The chapter ends with suggestions of key areas for future research that can bridge the gaps between these technologies and the needs of crisis managers.

Mobile Phones and Disasters

During a disaster situation, it is essential for people to communicate their need to be rescued. The global diffusion in mobile devices has greatly impacted how people use them during times of crisis and disasters (Chaoxu et al., 2019; Stephens et al., 2020), as well as during preparedness drills (Stephens et al., 2022). Maintaining effective communication like knowing what information to share, with whom, and through which channel is a pressing issue for individuals facing an emergency. The increased availability and usage in mobile devices, such as smartphones, tablets, and wrist watches, have provided people with the ability to take an active role in their own rescue (Stephens et al., 2021).

Prior to the availability of mobile devices, disaster rescue communication heavily depended on either official emergency personnel receiving information or people located in close proximity providing assistance. People who owned or had access to a two-way radio that could receive and transmit information communicated that way, but these devices were rarely used by anyone other than military personnel (Farnham, 2006). Aside from limited usage of two-way radios, people in communities with a working one-way radio or those within close proximity to the disaster were able to hear updates, and if sirens were broadcast, they also provided an auditory warning. Researchers studying local radio broadcasting during a tsunami in Indonesia found that one-way radios were important communication devices that allowed people to mitigate disasters and provided key information for preparedness, especially for under-resourced and underrepresented communities, but it depended on information being sufficient, accurate, and owning a radio (Romo-Murphy et al., 2011).

Mobile Alerts and Warnings

Mobile and cellular devices have improved from one-way communication systems to large-scale applications of alerts and warnings through text-based messaging. In the United States, Wireless Emergency Alerts (WEAs) are short emergency messages that crisis managers can send to people's mobile or cellular devices without the need to (a) live in the area of the emergency (i.e., geo-targeting); (b) the requirement to download an extra app; or (c) subscribe to a new service (FEMA, 2020). The emergency alerts issued through WEAs are short 360-character messages and have

recently added support for Spanish language alerts, although how this feature is used depends largely on the capabilities of authorities translating and distributing the messages (FEMA, 2020). WEAs are not unique to the United States; countries such as Japan also use alerts and messages through mobile or cellular devices to communicate emergency information (Bean et al., 2021a, b).

Automated emergency alerts through mobile phone communication allow quick delivery of potential or ongoing emergency events. As a result of geo-targeting on mobile phones, many people can receive alerts and warnings pertinent to their active current location. The effectiveness of WEAs is largely contextual, and lack of environmental or social cues to gauge the urgency of an emergency may delay rescues in disaster situations (Kim et al., 2019). In addition to understanding the limitations of reduced contextual cues, it is important to consider the political and cultural differences based on location (Bean et al., 2021b). Including a combination of features like newsfeeds commonly found in social media and/or the ability to mark individual safety through alert notifications may help improve the utility of the technology and better meet the information needs of crisis managers (Dijl et al., 2019).

Integrating Mobile Health

Public emergency alerts like WEAs are also being applied to contexts outside of weather-related disasters. Mobile health communication, or mHealth, better understood as “medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants (PDAs), and other wireless devices” (WHO, 2011, p. 6) can also be effective in helping people prepare and respond quickly to imminent threats (Bean et al., 2021b). mHealth alert systems have promising findings in helping slow the spread of infectious diseases (Bean et al., 2021a) and deliver support in resource-poor disaster settings (Callaway et al., 2012).

In hospitals, the use of mHealth mobile communication has increased practitioner’s efficiency by providing more timely and accurate patient assessments and improving response to patients in disaster scenes (Yarmohammadian et al., 2015). Experimentation with technologies in health settings has facilitated the implementation of mHealth in regions like Southeast Asia, the Americas, and Europe, but knowledge insufficiency, conflicting health system priorities, and lack of support from policies remain notable challenges (WHO, 2011).

Coordinating Search and Rescue

The coordination processes used during search and rescues have also experienced a change with the integration of mobile phones into disaster communication. Before, emergency personnel had to wait to receive distress signals through one-way communication channels prior to planning and enacting search and rescue missions

(Farnham, 2006). Now the affordances of mobile phones allow them to assist with the coordination and planning process by providing rescue information to crisis managers in real or near to real time. For example, emergency personnel in search and rescue teams are able to better know where clusters of people are located before and after a disaster, and they can track emergency personnel movement in the disaster area through the use of mobile phone location services (Chaoxu et al., 2019). Wireless search technologies also assist crisis managers in detecting and locating disaster victims even when phones are out of order (Hamp et al., 2014). This type of timely location data helps the planning and coordinating of search and rescue victims during critical emergency events.

Challenges Faced When Mobile Phones Cannot Be Used

Mobile Infrastructure and Reliance

The integration of mobile devices into daily activities has created a dilemma: people are so dependent on these devices for their day-to-day interactions that they also expect them, and their related cellular or Internet services, to be available during disaster events (El Khaled & Mcheick, 2019). When mobile infrastructures fail, the reliance on mobile devices creates new challenges both for the public in need of help and for crisis managers who provide assistance. In the United States, the collapse of mobile infrastructure was felt throughout Puerto Rico during Hurricane Maria in September of 2017. This made one- and two-way communication through mobile devices difficult and, in some instances, impossible due to power outages and loss of cellular connectivity (Nieves-Pizarro et al., 2019). Even in disasters, such as Hurricane Harvey in Houston, Texas, USA, where complete service was not lost, diminished service and the inability to recharge cellular devices change how people communicate their needs for help and rescue (Stephens et al., 2021). Although infrastructure failures impact everyone in the disaster area, they are felt most adversely by people already under-resourced and underrepresented, further impacting social and digital inequalities (Madianou, 2015).

Accessibility and Overcoming Global Disadvantages

While not everyone has access to a mobile device and the quality of Internet connection varies, around the globe, over 59% of people do have access to Internet services, and over 92% of this global population accesses the Internet through a mobile device (Johnson, 2021). In developing areas where opportunities to access the Internet are limited due to a lack of communication infrastructure, technology leapfrogging (i.e., the adoption of modern systems by companies or organizations allowing emerging countries access to modern technologies, such as mobile phones, without going through a lengthy infrastructure process) has provided a way to gain connectivity making cellular service more accessible (Tan et al., 2018). As mobile

Table 1 Mobile device possibilities and challenges during disasters

Mobile devices helpful during disasters	Challenges of relying on mobile devices during disasters
Accessibility:	Lack of mobile device access: <ul style="list-style-type: none"> Under-resourced individuals and communities may not have mobile devices.
<ul style="list-style-type: none"> Use devices to text, call, and post on social media. Access documents/information on websites. Communicate disaster help needs. 	Lack of access to power for the mobile device: <ul style="list-style-type: none"> The two-way nature of communication is not possible, and people must rely on radios or waiting to receive help.
Connectivity beyond the device:	Uncertain reliability of connectivity: <ul style="list-style-type: none"> Mobile infrastructure collapses—No cell service and no ability to get help. The two-way nature of communication is lost, and sharing requests for help is no longer possible. Help options are only possibly from face-to-face interactions.

devices have become more affordable, locations such as Asia and Africa have been able to increase mobile usage and connectivity by utilizing leapfrogging techniques in areas that previously lacked the necessary sustainable mobile infrastructure (Cilliers, 2021). China saw an impetus of leapfrogging digitalization in digital industries and applications brought forth by technology demands during the rapidly evolving COVID-19 pandemic (Xiong et al., 2021). Having greater accessibility to mobile devices in areas that previously lacked strong mobile infrastructure connectivity can be lifesaving when seeking help during a disaster.

Table 1 provides a summary of how mobile devices have created helpful ways to communicate during disasters, as well as what happens when social and economic inequities make them unusable or unusable and when infrastructure breaks down. Over time, leapfrogging has helped expand the number of people with access to digital devices, but that access is fragile and dependent on having access to power and ways to transmit signals (Stephens et al., 2020).

Mobile Phones and Social Media

This chapter uses the term social media to mean more than just social network sites. They are communication platforms where people “consume, produce, and/or interact with streams of user-generated content provided by their connections on the site” (Ellison & boyd, 2013, p. 158), as well as discussion forums and platforms such as Twitter, Facebook (Meta), WhatsApp, WeChat, and private platforms such as Nextdoor. Public, semipublic, and private social media platforms play important roles during disasters. Next, this chapter discusses how people use them to seek help,

how they are used by volunteers and crisis managers, and how they function to provide an important data source for situational awareness during response and recovery.

Social Media and Getting Help

Mobile phones with Internet capability can provide people with direct access to social media, and when people need help during a disaster, these platforms provide an effective way to make their rescue needs visible. For example, people can take photos to show the seriousness of their situation, they can post a call for help that can be forwarded to others, and they can have their friends and family post messages on their behalf if they are unable to recharge a failing mobile device (Stephens et al., 2020). Social media can also be used to connect people to sources of volunteer help and to coordinate the delivery of help resources (Palen & Hughes, 2018; Smith et al., 2021). Having platforms that connect people are important because there are often limits to the type of help official disaster responders can provide.

Social Media and Emergency Managers

While social media of many different forms have infiltrated most parts of everyday life, crisis managers are underutilizing social media in their decision-making (Lachlan et al., 2018; Peterson et al., 2019). The biggest reasons they are reluctant to use social media are policies that are unclear or forbid them to use social media, a lack of staff and skills to monitor and respond, and concerns around trustworthiness and the sheer volume of messages generated through social media platforms (Plotnick & Hiltz, 2016). When people need help during a disaster and emergency personnel are not providing the public with timely responses, they turn to public platforms, like social media, to share their stories and request help (Seeger & Sellnow, 2016; Stephens et al., 2020).

Using People to Help Identify Meaningful Data

As the prevalence and accessibility of mobile devices have increased, so has the use of social media. As more people use social media, vast quantities of text, image, and geo-location data are being generated (Alam et al., 2018; Qazi et al., 2020). Social media platforms—e.g., Twitter and Facebook (Meta)—provide content including posts related to requests for help, offers of help, locations where help is needed, and contextual information that can be leveraged to benefit disaster response (Li et al., 2019; Murthy & Gross, 2017; Stephens et al., 2020). These data can be collected and studied in myriad ways, including analyzing the content posted on social media, examining user interactions with one another, and tracing behaviors like joining groups or following/linking to another user or web pages (Senarath et al., 2021). By

analyzing social media content, public behavior during disasters can be characterized, which can enhance disaster-related decision-making.

Crowdsourcing and Disasters

Considerable research in the area of crisis informatics has identified the roles that volunteers play during and after disasters (e.g., Palen & Hughes, 2018). Research studying the use of social media during Hurricane Harvey in the United States identified specific types of rescue roles that volunteers play ranging from physically rescuing others to locating transportation and food, as well as coordinating responses for people in need (Smith et al., 2021). Additionally, these scholars found that volunteers used many different publicly available platforms beyond just social media—e.g., shared Google docs, mapping apps, radio apps, and websites—that allowed them to connect people who needed help to resources, including other volunteers who rescued people stranded on the roofs of their homes (Smith et al., 2021).

Some of the biggest problems for crisis managers with the data being generated by social media are sorting through it and finding the meaningful posts in a sea of irrelevant information (Murthy & Gross, 2017). To address this, one solution has been to include volunteers to assist in searching through the data, and thus they have become a vital part of disaster response. For example, during the Haiti earthquake in 2010, a live crisis map was launched to map out citizen's locations. Volunteers from the community were recruited and trained to process the large amount of location information received from citizens. The Haiti crisis map aided the disaster rescue and saved hundreds of lives (Meier, 2012). In the same vein, other disaster rescue teams employ a trusted group of volunteers as the backbone of disaster rescue efforts, such as Community Emergency Response Teams (CERTs) and Virtual Operation Support Teams (VOSTs) (Senarath et al., 2021).

Crowdsourcing is another approach to describe the contributions from a large, often undefined network of people, which has become an important method of processing social media data during disasters (Kirilenko et al., 2017). Crowdsourcing can be understood as lying at the intersection of a crowd (of people), outsourcing (labor), and advanced Internet technologies (Saxton et al., 2013). Platforms such as Amazon's Mechanical Turk are often used to pay people to perform crowdsourced disaster work (Kirilenko et al., 2017).

With the rise of employing volunteers and crowdsource workers to assist disaster management, a key concern has been the quality of workers' contributions. Researchers have found that volunteers and crowdsourcing workers are willing to devote more time to their tasks and produce higher-quality work when they are excited to participate and the tasks are perceived as meaningful (Tang et al., 2021). Studies have also found that crowdsourcing workers can be more efficient compared to employing volunteers, but the accuracy of the processed data warrants high-redundancy design, which leads to higher expense, therefore, to improve the accuracy. Kirilenko et al. (2017) suggest limiting the workers' pool to countries where the

research topic is actively discussed by the public. In an effort to overcome some of these quality concerns, Pandey et al. (2022) have found that while humans can make mistakes due to lack of attention or incomplete knowledge, AI-infused ICTs can help people identify the systemic sources of the mistakes they make. Therefore, by pairing humans with machines, there may be ways to further enhance the performance of identifying important information for disaster response and recovery.

Rise in Using AI-Infused Information Technologies

With more artificial intelligence (AI) technologies and machine learning practices being developed to aid in disaster rescues and management, the demand for efficient ways to process large amount of data that can be used to train AI-infused technologies is on the rise. Situational awareness refers to the understanding of the “big picture” in an emergency situation that allows for interpreting situations, making decisions, and predicting future outcomes (Vieweg et al., 2010). Scholars have demonstrated various technological capabilities to obtain situational awareness and assist crisis management efforts by leveraging different types of social media content and putting humans in the loop of processing this data. Existing technological systems, such as Artificial Intelligence for Disaster Response (AIDR) and CitizenHelper, use visual displays that provide a summary of social media content during the crisis according to temporal, spatial, and thematic aspects (Imran et al., 2015; Imran et al., 2020; Karuna et al. 2017). Some of these systems are being further developed to more fully leverage AI (Pandey et al., 2022; Senarath et al., 2021). Furthermore, with the advancement of artificial intelligence, researchers can build models not only to successfully classify social media disaster content but also to enable the training of real-time classification of social media with a smaller training dataset than in the past (Johnson et al., 2020). Regardless of the system being developed, they often rely on textual content, visual image analyses, and geo-location data.

Leveraging Textual Content

Given the importance of on-topic social media messages for situational awareness, AI-infused technologies are helping to extract relevant information from social media. Imran et al. (2013) describe a system that automatically extracts information nuggets from Twitter messages and uses machine learning techniques to effectively classify messages by creating structured information from unstructured textual content. Similarly, other researchers have developed various machine learning models by using social media textual data that are labeled with relevant and classified behavior types (e.g., Purohit et al., 2018). These models can assist decision-making during disasters and serve specific purposes such as automatically inferring risk behaviors from social media posts (Senarath et al., 2021) and discovering and ranking serviceable requests posted on social media (Purohit et al., 2018).

In addition, to accommodate automated systems functioning in environments where information is posted in various languages, researchers have built disaster-specific multilingual terminology resources and language-specific natural language processing (NLP) tools to support language translation of social media messages and cross the language barriers (Bügel & Zielinski, 2013).

Leveraging Image Content

Social media allows users to easily share information with more detail by providing ways to post images during disasters. Visual content can provide more information about the severity and extent of damage caused by a disaster than texts alone and offer more detailed understanding of the situation (Imran et al., 2020; Robertson et al., 2019). Researchers have explored how various AI techniques, such as NLP, machine learning, advanced data visualizations, and human computation, can move beyond textual content and leverage visual content generated during disaster events (Alam et al., 2018; Imran et al., 2020; Robertson et al., 2019). For example, Imran et al. (2020) launched an automatic image processing system during Hurricane Dorian to collect tweets relevant to the disaster and identify images useful for decision-makers responding to the disaster. The damage reports identified by the system were assessed by experts, who determined that the classifications were fairly accurate. Further investigations found ways to improve the models that included incorporating more training data on flooded and strong wind scenes (Imran et al., 2020). In addition, imagery content can be combined with textual content for damage analysis to enhance or complement the information contained in a single modality (e.g., text). This practice has led to studies on multimodal social media content, consisting of both images and text with the goal of improving the overall model performance (Alam et al., 2018; Mouzannar et al., 2018; Sosea et al., 2021).

Geo-referencing Information

In addition to textual and image content, geo-referencing information can provide an additional layer of data for analysis. Social media data with geo-referencing information—defined as identifiable location data—can be used to create an interactive map-based visualization that provides additional geographic context for analysis. This can be used to better identify social media users who are geographically vulnerable to impending disasters and make rescue decisions (Anderson et al., 2019). During a pandemic, location data are essential for many tasks such as disease tracking and predicting (Brennan et al., 2013). For example, during the COVID-19 pandemic, researchers collected a large-scale, multilingual, geo-located Twitter data and employed computational models to gain a better understanding of how societies are collectively coping with the unprecedented pandemic (Qazi et al., 2020). This can inform the development of AI-based systems to forecast disease outbreaks, which depend on having geographic data incorporated into their forecasts.

Network Data

A final type of data that could be useful in a disaster is network data, ties among social media users that can be utilized to create a more complete view of crisis-related information posted on social media. For instance, researchers used a network-filtering method for social media data collection and discovered that by combining this approach with location and keyword-based methods, their models can contribute significantly more insight into disaster situational awareness (Grace et al., 2019). However, getting complete network data can be a real limitation of this method, especially considering that so many people limit access to their location information, often due to privacy concerns.

Privacy Issues

Since the data fed into disaster-related AI technologies is most often social media data, several characteristics of this data must be considered. Because social media content is directly created by end users, it can carry personally identifiable information, something that raises privacy concerns. For example, geo-location may reveal users' exact location which can be used to rescue people (Stephens et al., 2020), but it can also be used for surveillance purposes (Qazi et al., 2020).

Due to the typical time-critical nature of disaster response, privacy is often not prioritized during active disaster management (Löchner et al., 2020), yet retaining data and using personally identifiable data can be an important privacy concern. For example, social media users may share their personal information publicly on social media platforms to receive timely rescue during a disaster, and then once they are safe, they may try to delete their post afterward. However, the post may not be fully deleted because it can remain as a copy in a dataset downloaded and stored by a third party. Such data retention opens the risk of possible abuse, theft, and accidental public exposure (Miller, 2020). While many researchers are trying to tackle this issue, one team has developed a method to store and process data from any social media service in a privacy-aware fashion by immediately splitting data into its atomic pieces upon data collection and dissolving direct relations between data (Dunkel et al., 2020). While such an application cannot eradicate privacy issues associated with collecting publicly available social media data, it provides a basis for a better integration of privacy considerations in disaster management.

The integration of geo-referencing data into crisis analysis also entails challenges. For example, there are distinctions between different forms of geo-referenced data such as geo-coordinates (latitude, longitude), place field, and content field (Qazi et al., 2020). Geo-coordinates are received from social media platforms' geo-location service if enabled by users, and these geo-coordinates offer the most accurate user location information. Place field provides location information tagged by users, which may or may not reflect users' actual location. In addition, users may indicate explicit or implicit location information in the content field using text, which often entails ambiguity about geo-/non-geo-information (Imran et al., 2015). A

geo-/non-geo-ambiguity can create confusion for a person or a computer when trying to understand and label social media data. For instance, in the message “Let’s play Texas hold ‘em,” the word, “Texas,” does not refer to a location in the state of Texas in the United States; Texas hold ‘em is actually the name of a game that people play, and thus this geo-/non-geo-ambiguity can create serious data issues (Imran et al., 2015).

Future Research on ICTs and Disasters

ICTs are changing, and their capabilities are increasing almost daily, yet people cannot be separated from the study of ICTs since they will ultimately decide how and when they use these technologies. This invites a host of research opportunities centered around mobile devices, social media, and AI-infused technologies. This chapter provides several directions forward as scholars continue taking cues from practitioners and people experiencing disasters.

While there is a growing body of research trying to understand how mobile devices are used to seek and provide help during disasters, there are still opportunities to better grasp the role that images play in helping people get rescued. It is also important to study the range of capabilities when people only have access to low-bandwidth Internet and thus must rely on text-based options or applications that work in lean bandwidth conditions. This is often the case in disasters; therefore dialing down the range of communication options could provide some of the most wide-reaching, helpful research. Using mobile device capabilities to deliver early warnings also is promising, but moving forward, scholars need to consider culture as well as how to use language to motivate people to action (Bean et al., 2021b). Messages delivered in brief formats need to be designed for maximum impact; therefore, experimental designs testing actual messages can provide insight into what will motivate people to action.

Social media data can be very helpful during disasters, yet several big challenges can impact the usefulness of this form of data. Data privacy and access issues are very real considerations during disasters, and scholars should further explore these. Another challenge that needs considerably more research is identifying mis- and disinformation and separating these from actionable situational awareness data. Not only is this a challenge for people needing help during a disaster, but it can undermine the trust that crisis managers have in using social media data. While it is difficult to get access to private social media data, in the few studies that have researched, it appears people try to provide accurate information, but even with good intentions, people can mistakenly post incorrect information and can be influenced by their own personal beliefs (Li et al., 2019; Stephens et al., 2020).

AI-infused technologies offer considerable promise, but scholars need to better understand the limits of these technologies and where other research methods might reveal richer or more accurate data. For example, Robertson et al. (2019) compared

human-coded content analysis and supervised machine learning results and found that unique disaster experiences are not always captured through machine-learned methods. There are likely times when hand-coding data will yield the best results, but that will likely be in smaller datasets where the manual task is possible. Qualitative research methods can also capture many more narratives around disaster research and response (e.g., Stephens et al., 2020, 2021), as well as serving as a method useful in tandem with AI technologies to provide richer insight into AI findings.

Scholars studying AI-infused technologies in disaster contexts are increasingly working with emergency practitioners (e.g., Pandey et al., 2022; Peterson et al., 2019), and this is vital to understanding the needs of official emergency response communities. Around the globe, the emergency and disaster response communities need more resources than they often receive (e.g., Peterson et al., 2019), and with the proliferation of social media data, they can rarely capitalize on using this data for situational awareness. Yet making the leap from using AI-infused technology for research to getting it into the working operation of crisis managers is difficult. This will require expanding research teams to include experts in user-centered design and human-AI teaming and communication, along with improving the accuracy of machine learning. It will also be important to have crisis managers on the team with researchers, because they can help overcome another challenge: getting the broader emergency response community to trust these automated systems and when to keep humans in the loop. This interdisciplinary endeavor is important to advance the meaningfulness of this research area.

Conclusion

ICTs play a pivotal role in disaster response and recovery because their features can meet the information and communication needs of crisis managers. People who have mobile devices are capable of participating much more broadly in conversations that include social media and thus increase exposure to their calls for help. As more people use social media during disasters, this creates new data volume and quality issues for crisis managers, gaps that disaster scholars are actively trying to bridge. AI-infused technologies offer one solution, but for the near term, keeping humans in the loop will be essential because their local knowledge can fill gaps that machines cannot comprehend. Not all solutions to these disaster data challenges involve technologies, but quite often ICTs open additional possibilities as we improve situational awareness for official disaster responders and save more lives.

Abstract

Once a disaster occurs, the common practice nowadays is that people check social media platforms, where the news usually breaks, to find out up-to-the-minute situational updates. In fact, news agencies do likewise, not only individuals. Among the important information that is needed during disaster events is

geolocation information (e.g., where the disaster event has happened, where affected people are situated at that moment, etc.). Such information plays an essential role in disaster management for affected people and also for response authorities such as the Intergovernmental Organizations (IGOs) and Non-governmental Organizations (NGOs). It helps affected people to share accurate updates on their status, their needs, and the emerging incidents, which enable a rapid response. Furthermore, the geolocation information allows response authorities to manage their response activities (e.g., routing rescue teams), and reduce the impact of disasters by planning future activities (e.g., evacuation). This chapter links stakeholders' requirements with existing computational methods for geolocation inference and introduces the computational tasks that fulfill the stakeholders' unmet needs. It also discusses the Location Mention Prediction (LMP) task due to its key role for tackling all geolocation tasks. Moreover, it discusses different categories of challenges associated with LMP subtasks, reviews the existing solutions for each and their drawbacks, and sheds light on a few future directions.

Introduction

Disaster response authorities rely on *Crisis Maps* built using situational and actionable information gathered from heterogeneous data sources to activate response efforts, ideally, within the first 48–72 h of a disaster (Five essentials first 72 hours disaster Ziemke, 2012). Crisis maps leveraging situational information provide the big picture of a mass emergency and help response organizations understand various impacts of the disaster event in different geographical areas (Vieweg, 2012), for example, the cities that are most affected after a severe hurricane, the areas with high flood inundation, or the parts of a city with electricity outage. In all these cases, although at the coarse level, the geolocation information plays a critical role for authorities to understand affected geographical areas. Actionable information, on the other hand, refers to a particular type of information that contains a specific request that demands actions from a particular response authority (Zade et al., 2018). One important factor that makes such requests actionable is the location information specifying where the request is needed (Zade et al., 2018). Examples of crisis maps with actionable information include urgent needs of items such as food, water, and shelter in a specific area, location of a site where some people are trapped, areas where urgent medical assistance is required, or reports mentioning severe damage to critical infrastructure such as bridges, roads, and hospitals.

Crisis or disaster mapping refers to the real-time acquisition, analysis, and visualization of relevant information during a crisis (Ziemke, 2012). The process

of crisis mapping leverages multiple heterogeneous data sources such as mobile and web technologies, hotlines, volunteering, crowdsourcing, and physical surveys, to generate different types of maps useful for response organizations for timely decision-making and actions. However, during large-scale disasters, relying on traditional sources to perform real-time crisis mapping becomes challenging. As an alternative, several studies demonstrated the effectiveness of nontraditional data sources such as social networking sites and remote sensing to acquire real-time crisis information (Weber et al., 2021). For instance, the use of Twitter, which is a microblogging social media site, during disasters has been proven as a useful information source to gather time-sensitive situational and actionable data directly posted by the affected people (Hughes & Palen, 2009).

This work explores the use of Twitter to acquire different types of geolocation data to generate different types of crisis maps. Specifically, we analyze location information shared via Twitter messages during disasters to understand its effectiveness for crisis mapping. To determine the usefulness of location information present in tweets, we list down several response tasks and their information needs, specifically in terms of geolocation information, and discuss corresponding computational tasks useful to extract location information from Twitter messages to fulfill stakeholders' information needs. Although the chapter states several computational tasks, two of them, i.e., Location Mention Recognition and Location Mention Disambiguation, are discussed in detail.

The contributions of this chapter include an attempt toward linking stakeholders' requirements with existing computational tasks around geolocation inference tasks. Moreover, it defines new computational tasks that fulfill stakeholders' unmet needs. Lastly, it focuses the discussion on the *Location Mention Prediction (LMP)* task due to its vital role in all geolocation tasks and the entire emergency response pipeline. It describes the current status from the literature, associated challenges, and future directions. We refer the reader to the thorough survey of Zheng et al. (2018) for studies on *Tweets and User (or Home) Location Prediction* tasks. We are not aware of surveys for the remaining geolocation tasks. Additionally, a large body of existing studies tackle the LMR task in different data (e.g., news articles, research articles, etc.) and task domains (e.g., POI recommendation, traffic monitoring, etc.). However, this chapter is restricted to the research that has been conducted over Twitter in emergency scenarios.

The rest of the chapter is organized as follows. Section “[Response Information Needs and Computational Tasks](#)” links stakeholders' requirements and existing computational tasks. Section “[Location Mention Prediction](#)” provides an overview of the *Location Mention Prediction* task. Sections “[Location Mention Recognition](#)” and “[Location Mention Disambiguation](#)” discuss the *Location Mention Recognition* and *Location Mention Disambiguation* tasks, respectively, in detail including the problem formulation, associated challenges, existing literature, and evaluation tools. Section “[Challenges](#)” discusses further the Twitter- and emergency domain-specific challenges that have to be taken into account when developing LMP systems. Section “[Future Directions](#)” emphasizes limitations and shapes a few future

directions toward achieving the responders' requirements. Section “Conclusion” concludes with a brief summary of the chapter.

Response Information Needs and Computational Tasks

To model the stakeholders' information requirements into real-time computational tasks, this section elaborates on the specifications of their needs and formulates the problems accordingly.

Different experts in the disaster domain have participated in a study conducted by Hiltz et al. (2020) to understand the information needs of response authorities that can be supported by computational tasks. Their responses to surveys manifested the need for situational and actionable information accompanied by geolocation information.

What makes Twitter content invaluable is that witnesses to incidents do usually mention fine- (Kropczynski et al., 2018) and coarse-grained (Grace et al., 2018) locations while reporting incidents or stating needs. Several successful real-world examples of exploiting Twitter for disaster response are inspiring the responders from around the globe to cope with the new tools at hand, for instance, the deployment of the Ushahidi platform ([The ushahidi platform](#)) to map geotagged tweets during the Port-au-Prince earthquake in Haiti, 2010 ([Innovative uses of social media in emergency management](#)). Similarly, the geolocation information was used to map damages and requests during Typhoon Haiyan in Southeast Asia, in 2013. Furthermore, Fairfax County in Virginia, USA, offers an excellent case in point when they explored the usefulness of employing the Geofeedia platform to monitor and aggregate data from various social media platforms including Twitter. The platform is no longer available. Nevertheless, Twitter announced removing the geotagging feature in tweets, in June 2019.

There are different geolocation tasks defined in the literature over Twitter as follows:

- *Location Mention Prediction* (LMP): extracting toponyms from the tweet's text (Location Mention Recognition) and pinning them on the map (Location Mention Disambiguation) (Zheng et al., 2018). Bold text in tweets in Fig. 1 refers to the location mentions that have to be extracted and resolved.
- *Locational Focus Prediction*: inferring the most probable locational focus of a tweet, if multiple locations are mentioned (Yin et al., 2014). For example, the fourth tweet in Fig. 1 mentions multiple locations where different floods happened. The locational focus of this tweet is “Chennai” as the user is listing the number of donations by a celebrity for the Chennai floods among other floods.
- *Tweet Location Predicting*: estimating the geotags from where a tweet is posted (Zheng et al., 2018). Tweets in Fig. 1 are not geotagged by the user (the geotags feature had been removed by Twitter), hence this task should assign a location to every tweet. These locations could be mentioned within the tweet text or not.

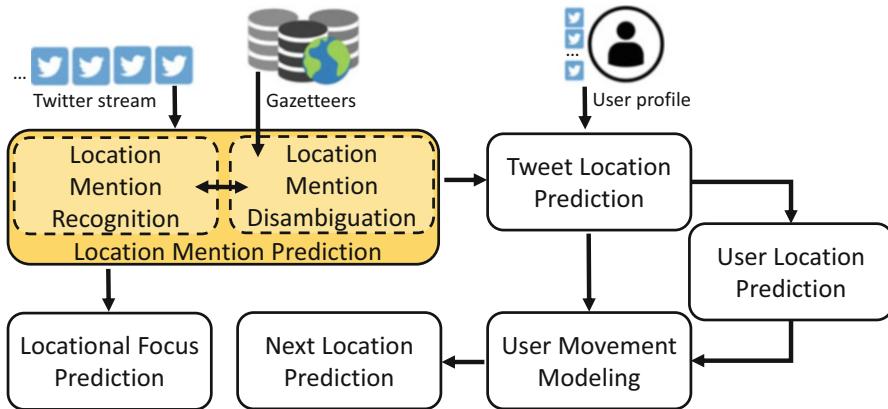

Fig. 2 Geolocation tasks and the interactions between their output

- *User (or Home) Location Prediction*: inferring the exact location where a user is living (Zheng et al., 2018). As shown in Fig. 1, the user set his location to “Chennai” which typically indicates his coarse-grained home location. This task is concerned with predicting the home (empty or ambiguous locations) or the current location of the user that could be outside her homeland.
- *User Movement Modeling*: mining the pattern of a user movement over time. People tend to write tweets while traveling over time.
- *Next Location Prediction*: forecasting the next place where a user might go (Wang & Gerber, 2015).

Figure 2 illustrates six geolocation tasks and the interactions between them.

The underlying usage of these six tasks enables responders to operate effectively and efficiently through several real-time applications such as disaster-specific routing, geographical-based recommendation, and geographical tracking based on social sensing. The usage of these real-time applications is delivered to stakeholders through different types of maps that are discussed below:

- **Situational awareness maps**: High-level situational awareness helps response organizations understand different types of impacts to different geographical areas (Vieweg, 2012). Situational maps assist response authorities in identifying the most affected areas, and the most vulnerable people, among other information that could be observed and acted upon such as planning evacuations ahead of upcoming developments. To map the disaster using Twitter data, a geolocation system should extract informative tweets about the disaster, perform *Locational Focus Prediction* on informative posts, and encode this information in *choropleth maps* that depict the aggregated information based on their locational focus in different geographical levels (e.g., state, city, street, etc.). The *locational focus* was not sufficiently studied in literature (Yin et al., 2014), and crisis mapping was studied in the aftermath of disaster events (Middleton et al., 2014) using different types of maps. Therefore, more attention has to be paid to this research direction.

- **Disaster development and impact maps:** Pinning different incidents on the map, especially the destructive ones, helps response authorities manage relief activities. Generally, disaster events cause infrastructure damages, power outages, airport closures, transportation outages, etc. Locating the consequences through choropleth and heat maps helps response authorities assess the impact to plan for recovery. Dynamic disruption maps (Roy et al., 2020) can present the severity of the disaster impact after applying statistical analysis of the information (e.g., the frequencies of locations could be an indication). This indeed aids in the planning of relief activities, for example, changing routes of responders to avoid damaged roads and bridges. Up to our knowledge, *disaster-specific routing systems* are not explored in the literature. To map the incidents and consequences during disaster events, a geolocation system has to detect on-topic tweets about incidents, perform *Location Mention Recognition* and *Disambiguation*, and put them on the map. In cases where the locations of incidents and consequences are not mentioned, the system could perform *Tweet Location Prediction* to understand whether the user is talking about a location he is currently visiting or living in to increase the reliability.
- **Eyewitnesses and resources maps:** Locating eyewitnesses, first responders, and resources are important to support assessing urgent needs. Visualizing eyewitnesses is needed to determine potential first aid treatment performers, for example. Linking the people in need to the first responders is a potential activity that could be achieved through specialized *real-time geographical-based recommendation systems*. Similarly, resources could be mapped using *proportional symbol and dot-density maps* to identify their status, shortage, adequacy, or abundance. Resources include human resources (e.g., volunteers and expert responders), facilities (e.g., shelters), funding (e.g., donations), and supplies (e.g., food and water), among others. To locate eyewitnesses and resources, a geolocation system may simultaneously perform *Tweet* and *User Location Prediction* tasks supported by content-based analysis and *Location Mention Prediction*.
- **Population mobility maps:** When a disaster event occurs, people living in the affected area have to evacuate in most cases which requires tracking their mobility and behavior. People displacement impacts the resource allocation and recovery plans; thus, *real-time geographical tracking systems based on social sensing* using *animated time-series maps* are of great support to trace the movement of the affected people. Also, modeling the user movement requires applying *User Movement Modeling* component that requires *Tweet Location Prediction*, *User Location Prediction*, and *Next Location Prediction*. Current studies rely on mobile Call Detail Records (CDR) but not on social media data. Additionally, modeling the dynamics and flow of evacuation is important during disaster events.
- **Response planning maps:** To plan relief activities, a major aspect to manage is the transportation of relief personnel from their location to the location of people in need. The planning maps could support various relief activities such as rescuing trapped people, tracing missing people, providing first aid for injured people, etc. While the subsequent incidents and consequences are mapped

already, performing the relief activities would be safer when responders are aware of and can avoid dangerous or out-of-service areas in their routes. *Real-time development-aware routing algorithms* that are up-to-date concerning the mapped incidents and consequences are required. The areas of incidents and consequences have to be avoided in planning the routes (Refer to the *Disaster development and impact maps*). Moreover, the routing algorithm has to collectively apply all geolocation tasks as applicable to decide the starting point, the multiple stop points, and the destination point.

As it turns out that the Location Mention Prediction (LMP) task is intrinsic to the other geolocation tasks that require content analysis of tweets to perform the prediction and modeling, this chapter focuses on the LMP task.

Location Mention Prediction

To articulate the role of an LMP module in the emergency management domain, a high-level computational response pipeline is depicted in Fig. 3. While the Twitter are noisy and shared at a very high rate, the responders demand high-quality situational reports and actionable tweets to make decisions and deploy relief activities accordingly. Hence, prefiltering modules have to be implemented – upstream tasks are shown in Fig. 3.

Among these tasks are (i) relevance filters: to discard all irrelevant content to the target disaster event; (ii) qualification filters: to filter out spam, rumors, bot-generated content, etc.; and (iii) informativeness filters: to filter out sympathy, opinions, criticism, etc. The prequalified tweets continue to the LMP module that constitutes two main components for (i) Location Mention Recognition (LMR) to extract toponym spans from the text of tweets, and (ii) Location Mention

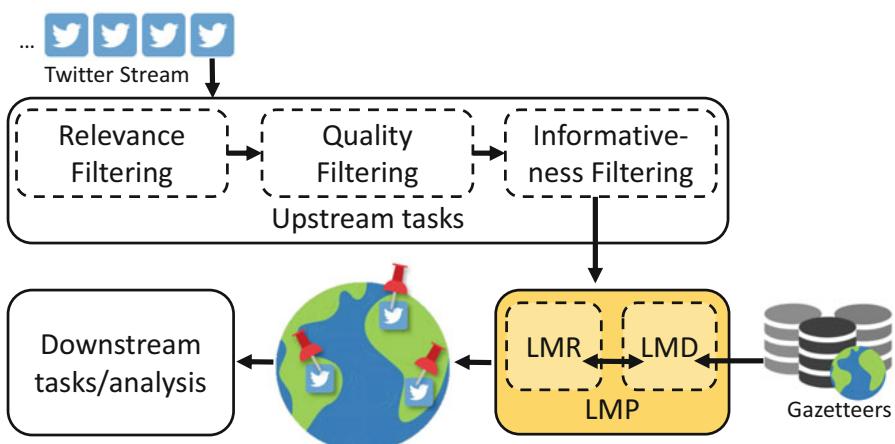

Fig. 3 Locating the LMP task in the disaster response pipeline

Disambiguation (LMD) to link the potential-extracted LMs to existing toponyms in a geo-positioning database (i.e., gazetteer). The output of the LMP module can be then directly used by the disaster response authorities, or fed into other downstream tasks such as mapping services.

The recognition and disambiguation tasks have different naming in literature. Some studies refer to recognition as extraction or geoparsing. The disambiguation is alternatively named resolution, linking (looking up a geo-positioning database to find matches), or geocoding (assigning geo-coordinates to LMs regardless of the sources used). In rare cases, geoparsing could refer to both LMR and LMD tasks. For clarity, recognition and disambiguation terminologies are used throughout this chapter.

Location Mention Recognition

This section starts with the formulation of the LMR task in section “[Task Formulation](#).” It then discusses the challenges associated with it in section “[LMR-Specific Challenges](#),” dives into different categories of proposed solutions in the existing literature in section “[Literature Review](#),” and finally presents the evaluation tools and their shortcomings in section “[LMR Evaluation](#).”

The LMR task is generally defined as *the automatic extraction of toponyms from text*. The scope of this section is limited from two angles: The extraction is focused on *tweets*, and more specifically *disaster-related* tweets that are posted *during disaster events*. Figure 4 illustrates the high-level overview of the LMR task.

Task Formulation

The LMR task is formally defined as follows: Given a tweet t that is related to a disaster event e , the LMR system aims to identify all location mentions (LMs) : $L_t = \{l_i; i \in [1, n_t]\}$ in tweet t , where l_i is the i th location mention and n_t is the total number of location mentions in t , if any. The location mention may constitute one or more *tokens* in the tweet text. The location type can also be fine-grained (e.g., street, building, natural feature, etc.) or coarse-grained (e.g., country, state, city, etc.). Thus, the LMR task can be tackled in two setups: (i) *Type-Less Recognition*, where the

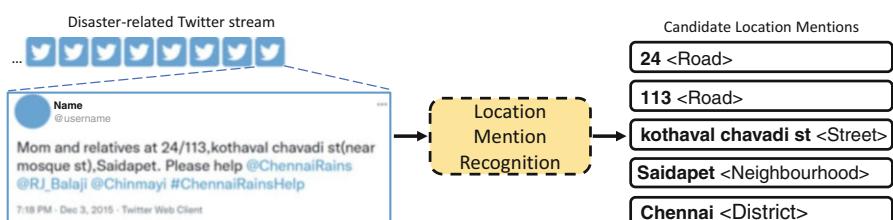

Fig. 4 High-level overview of the LMR task

Table 1 Tweets from real-world disaster events with location mentions (underlined). HRC, EQK, and FLD refer to hurricane, earthquake, and floods, respectively

Dataset	Tweet #	Tweet text

	#9	Flooding at <u>East 8th</u> and <u>Avenue C</u> before the blackout (GIF) [url]

system detects all potential LMs in the tweet text regardless of their types, and (ii) *Type-Based Recognition*, where the system detects LMs and predicts their types (e.g., city, country, street, POIs, etc.). All the existing LMR studies in the disaster domain propose *Type-less Recognition* approaches.

Table 1 shows a few example tweets shared during different real-world disaster events including *Chennai floods 2015*, *Houston floods 2016*, *Louisiana floods 2016*, *Christchurch earthquake 2012*, and *Hurricane Sandy 2012* (Al-Olimat et al., 2018; Middleton et al., 2018). These tweets are important for the relief organizations and first-responders, who rely on Twitter for effective management, as the tweets contain (i) situational reports such as incident or casualty statistics, the status of resources, etc., or (ii) actionable information, including the calls for rescue, requests for resources, need for volunteers, etc.

The LMs appear in different forms in tweets, such as:

- *Full address*: Examples include the location where rescue boats are needed in tweet #1, and the location of reported water levels in tweet #3.
- *Administrative divisions*: Different levels of administrative divisions are commonly mentioned during disasters. For instance, states are mentioned for high-level updates, such as “TX” and “LA” in tweets #3 and #5, respectively. Cities are also reported, such as “Valley Mills” and “Ocean City” in tweets #4 and #8, respectively. Neighborhoods are also mentioned, such as “Greens Bayou” in tweet #3.
- *Points-of-interest (POI)*: Examples include the location of a natural POI where a flood warning is issued, e.g., “Bosque River” in tweet #4, the location of a

human-made POI to report the status of children, e.g., the “Cashmere kindergarten” in tweet #7, or worship places, e.g., “Tangipaho Parish” in tweet #5.

- **Streets:** Examples include bridges, e.g., “Adayar Bridge Saidapet” and “TVK bridge” in tweet #2, and flooded streets, e.g., “East 8th” and “Avenue C” in tweet #9.

Moreover, due to the short length of tweet text limited to 280 characters, Twitter users lean to use abbreviation forms, such as “TX” and “LA” in Tweets #3, #5, and #6 and shortcuts such as “Rd” and “St.” in Tweet #3 and #5, respectively. The abbreviations and shortcuts cause the mismatch challenge that is discussed among other challenges in section “[LMD-Specific Challenges](#).”

LMR-Specific Challenges

The following different challenges arise when tackling the LMR task:

- ***Emerging location:*** Over time, the disaster event develops over the Twitter stream with new incidents and discussions. Hence, new unseen LMs emerge. Therefore, The LMR systems have to learn detecting the patterns of locations instead of memorizing the vocabulary of toponyms to generalize well to unseen data.
- ***Toponymic Polysemy:*** Location mentions might have different meanings referring to different entity types other than locations. For example, “Sabah Al Ahmad” could mean the “Sabah Al Ahmad city, Kuwait” or could refer to the former Emir of the State of Kuwait “Sabah Al Ahmad.” Thus LMR systems have to accurately distinguish locations from other entities, especially the unusual toponyms.
- ***Temporary locations:*** Temporary facilities (i.e., medical camps and shelters) are constructed during emergencies to provide resources and support the affected people. However, these facilities are disassembled (e.g., quarantine centers) once the emergency is over. Additionally, the names of some locations could change during emergencies, such as converting schools into shelters and giving them new expressive names (e.g., “main shelter”). Once the disaster event is over, schools will return to providing their original services. The difficulty of detecting and disambiguating these temporary locations is due to the need to comprehend their context.

There are challenges associated with the gazetteer-based solutions, including the “mismatch” and “incompleteness of gazetteers” issues, that are discussed in section “[LMD-Specific Challenges](#)” in detail.

Literature Review

Existing studies exploit different techniques and features to extract location mentions (LMs) from text (Zheng et al., 2018). It is worth mentioning that, comparing the performance across approaches is unattainable due to the absence of a unified evaluation framework for a long time including datasets with standard training and test splits, and public evaluation scripts. Recently, Suwaileh et al. (2023) released the largest to date public and generalizable LMR datasets. Hence, the discussion and comparison of approaches in this section will solely focus on the methodology.

NER-Based Approaches with Domain Transfer

LMR can be considered a subtask of a more general task of detecting entities (e.g., people, organizations, locations, etc.) in text, which is known as Named Entity Recognition (NER). Therefore, a naive solution would be to start from NER by applying the existing NER models for extracting LMs. Interestingly, the explored transfer-learning directions are not limited to only employing the existing NER models, but researchers have also used the NER datasets to train their LMR models. For instance, Lingad et al. (2013) explored the effectiveness of four off-the-shelf NER models on toponyms extraction over disaster-related tweets. The models are StanfordNER (Finkel et al., 2005), OpenNLP (Apache, 2022), Yahoo! PlaceMaker (No longer available), and TwitterNLP (Ritter et al., 2011). Both StanfordNER and OpenNLP allow custom training; hence, Lingad et al. retrained them using Twitter data. TwitterNLP provides the option to expand the Freebase dictionary. The study showed that StanfordNER is the top-performing tool after retraining it with Twitter data; otherwise, it poorly detects LMs. The OpenNLP comes next with the same retraining condition. Following this intuition, Gelernter and Balaji (2013) developed GeoLocator tool that uses OpenCalais NER tool to extract toponyms and facilities (i.e., buildings). In an effort to combat the gazetteer incompleteness issue, they augmented OpenCalais with a list of building types to improve its recall when detecting buildings.

Later, the StanfordNER tool was commonly employed in LMR studies due to its superiority (Ghahremanlou et al., 2015; Liu et al., 2014; Mao et al., 2019; Nand et al., 2014; Yin et al., 2014). The original StanfordNER model is trained on newswire articles. The first LMR shared task organized by the research community was part of the Australasian Language Technology Association (ALTA) Workshop 2014 (Molla & Karimi, 2014). Among the four participating teams, a couple of them used the StanfordNER tool for toponyms recognition. One team used it in a data transfer mode, as a pretrained model within an ensemble LMR system with rule-based modules that identify abbreviations and location specifiers in text (Nand et al., 2014). Alternatively, Liu et al. (2014) retrained the StanfordNER model over the ALTA training data. Ghahremanlou et al. (2015) and Yin et al. (2014) had also retrained StandfordNER using tweet datasets aiming at improving its effectiveness. Furthermore, Mao et al. (2019) compared three NER models including the original StanfordNER model, a retrained version of it with tweets, and Bi-LSTM model to map the places where power outages happened using Twitter data.

Recently, Nizzoli et al. (2020) have used the NER dataset from the Named Entity rEcognition and Linking (NEEL) challenge (Rizzo et al., 2015) to train their LMR model. They then employed the off-the-shelf TAGME tool (Ferragina & Scaiella, 2010) to capture meaningful short phrases in the text and match them to Wikipedia articles to identify the LMs in the text. Wang and Hu (2019a), alternatively, retrained the three top systems from the Toponym Resolution in Scientific Papers task, which was held at SemEval 2019 (Weissenbacher et al., 2019), on CoNLL 2003 NER Web dataset (Tjong Kim & De Meulder, 2003). The systems are, namely, *DM_NLP* (Wang et al., 2019), *UniMelb* (Li et al., 2019), and *UArizona* (Yadav et al., 2019). These systems recognize and disambiguate entities using independent components. The recognition components of all of these Toponym Resolution systems are, at their core, Bidirectional Long Short Term Memory (BiLSTM) models (Discussed further in section “[Riding the Wave of Deep Learning Models](#)”). The disambiguation components of these systems are discussed in section “[Literature Review](#).[“](#) Furthermore, to create dynamic disruption maps during disaster events, Roy et al. (2020) extracted LMs from tweets’ text using the NLTK-NER model (Bird et al., 2009).

Following this line of research, Cite Suwaileh et al. (2020) and Suwaileh et al. (2022). empirically investigated the usefulness of transfer learning over multiple datasets from two angles: (i) training LMR models on Web (CoNLL-2003 (Tjong Kim & De Meulder, 2003)) versus Twitter (BTC (Derczynski et al., 2016)) general-purpose NER data, and (ii) training LMR models using all types of entities versus only the location entities. They composed four setup combinations and compared them to training on only disaster-related LMR Twitter datasets. Their study recommends a preference of dataset types based on the performance gains when used for training LMR models. The best scenario is to train the LMR models on disaster-related LMR data whenever available. Otherwise, Twitter general-purpose NER data is put forward, then the Web general-purpose data is recommended when no other resources are available for training. Additionally, Cite Suwaileh et al. (2020) and Suwaileh et al. (2022) suggest limiting the training on location entities, rather than using all types of entities, to remarkably improve the LMR performance.

Takeaway Messages: The key motivation of the *domain transfer recognition* approaches is to mitigate the response latency of relief authorities at the onset of a disaster event. The latency might occur due to the costly annotation of target disaster data. Directly applying the NER models trained on web data is not the best option during emergencies. Hence, when data from disaster-related data is not available, the Twitter NER datasets, with solely location entities, provide a valuable resource for training acceptably performing LMR models.

Gazetteer-Based Approaches

The subsequent research direction was to develop disaster-specific LMR models. To achieve this, the intuitive approach is to verify the potential LMs against a geolocation database (i.e., gazetteers) while detecting them. Many of the existing LMR models are gazetteer-based models with two main components (Al-Olimat et al., 2018; Dutt et al., 2018; Gelernter & Balaji, 2013; Malmasi & Dras, 2016; Middleton et al., 2018): (i) *extraction*: aims to detect potential LMs in text, and

(ii) *retrieval*: aims to link the candidate LMs with toponyms in gazetteers. Hence, these approaches could be categorized under joint recognition and disambiguation, as the resulting LMs correspond to existing toponyms in gazetteers.

Several existing gazetteers were employed in the gazetteer-based approaches, including Geonames (Dutt et al., 2018; Malmasi & Dras, 2016), OpenStreetMap (Al-Olimat et al., 2018; Dutt et al., 2018; Middleton et al., 2018), and National Geospatial Intelligence Agency gazetteer of New Zealand (Gelernter & Balaji, 2013), among others.

The gazetteer-based approaches extract LMs from the textual content; however, they do not qualify LMs before verifying them against a gazetteer. For example, after extracting candidate LMs using OpenCalais NER model, the GeoLocator (Gelernter & Balaji, 2013) matches (exact matching) the extracted toponyms and building names against a gazetteer after correcting misspellings. To alleviate the mismatch issue between the user-generated text (tweets) and gazetteers, GeoLocator expands tweets with abbreviations and acronyms using a C4.5 decision tree classifier. Middleton et al. (2018) proposed *map-database* approach that relies on direct matching with the gazetteer. An index of locational phrases is constructed by augmenting different variations of LMs in OpenStreetMap gazetteer using a set of heuristics. The collected variations are represented in n-grams before being indexed and searched. All combinations of n-grams tokens of the input tweet are issued against the index of the locational phrases.

Another direction for matching gazetteers is utilizing language models. For instance, Middleton et al. (2018) adopted a language modeling approach, namely, the *lmtags-gazetteer* proposed by the top team in the MediaEval 2016 Placing Task (Kordopatis-Zilos et al., 2016) after extending it for location entities. The extended system uses gazetteers and a large geo-tagged social media dataset (Flickr posts) to build a language model. The language model is computed on a regional basis to account for highly indicative terms of specific locations.

Similarly, Al-Olimat et al. (2018) proposed an unsupervised statistical approach to construct regional language models. Their tagger identifies the LMs by traversing a tree of n-grams while matching them against a prebuilt region-specific gazetteer. Alternatively, Dutt et al. (2018) apply syntactical heuristics to identify candidate LMs before matching them against gazetteers. After identifying the nouns in text using a POS tagger, they consider the candidate nouns followed by common suffixes as LMs. A suffixes list is precompiled using different naming conventions of locations (e.g., streets, cities, etc.). They also constructed a prefix list of prepositions (at, in, etc.) and directions (north, south, etc.) to tokenize text.

Takeaway Messages: Acquiring labeled data is a key bottleneck during emergencies. The elegance of gazetteer-based solutions lies in their essence being unsupervised approaches that enable them to evade the need for acquiring annotated data at all. Additionally, the gazetteer-based approaches do achieve high precision levels. However, albeit being training-free models and highly accurate, they have two main drawbacks. First, the noisiness of Twitter streams causes the mismatch issue between textual content of tweets and gazetteers which introduces two challenges: (i) the need for careful preprocessing (e.g., spell checking), and (ii) the need

for augmenting all variations of the LMs including their abbreviations and acronyms into gazetteers for more effective matching. As an alternative, these steps could be replaced by semantic text representation models. Second, the incompleteness of gazetteers affects the performance of LMR models when detecting correct LMs that do not exist in the used gazetteer. These two challenges are discussed further in section “[LMD-Specific Challenges](#).”

Learning-Based Approaches

The machine learning-based (ML-based) LMR models alleviate the limitations of the gazetteer-based LMR solutions. The virtue of ML-based approaches lies in their promising ability to generalize beyond the seen data if supported with (or inherently learned) useful features.

Before discussing the ML-based models, we first discuss the different features used to train those models. Note that all features are token-level features (except one type of the geographical features and the temporal features), as the LMR task here is defined to be a sequential token-level tagging/classification task.

Textual features: While words are the essential component of tweets, they constitute the basic feature to be used in all ML-based approaches. Tweet text is tokenized using different techniques, and the resultant tokens are used to represent each tweet as a bag-of-words. *N-grams* are employed at both word- (Finkel et al., 2005; Han et al., 2014; Li & Sun, 2014) and character- (Xu et al., 2019) levels for the LMR task.

Lexical features: Following the NER tools behavior that heavily relies on *capitalization* to identify entities, especially in formal documents, different cases of capitalization are used by the LMR models (Han et al., 2014; Li & Sun, 2014) including all characters uppercased, all characters lowercased, only the first character uppercased, mixed capitalization, the prior probabilities of the lowered form of the token having the first character capitalized, and the prior probabilities of having all characters capitalized. While capitalization shows a strong signal for entities, in Twitter, and social media in general, users typically ignore capitalization; thus, letter case correction could be applied before recognition. In addition to that, an indicator feature for whether a token is numeric or alphanumeric was also used for the LMR task (Li & Sun, 2014).

Contextual features: The bidirectional context of tokens is usually considered for the Conditional Random Fields (CRFs) classifiers to capture the boundaries of locations by adding the adjacent words within a window of a maximum size of 2 (Finkel et al., 2005; Han et al., 2014) or 5 (Li & Sun, 2014). Furthermore, *word embeddings* have been used for the LMR task (Kumar & Singh, 2019; Suwaileh et al., 2020; Xu et al., 2019) to contextually represent tokens/tweets using pretrained models such as GloVe (Pennington et al., 2014) and BERT (Devlin et al., 2019).

Syntactic features: Assigning the *Part-Of-Speech tags* (POS), e.g., noun, verb, and adjective, among other types, to words (or tokens) showed to be effective when combined with other features (Finkel et al., 2005; Han et al., 2014; Li & Sun, 2014).

Geographical features: To trade-off between precision and recall, a few studies (Han et al., 2014; Li & Sun, 2014; Xu et al., 2019) prelabeled the tweet tokens using

a toponym inventory which has been proven to be influential on the LMR performance. To build the toponym inventory, Li and Sun (2014) labeled the common names of POIs mentioned in tweets with the associated Foursquare check-ins. This method generates a Twitter-like noisy POI inventory. Alternatively, Han et al. (2014) combined GeoNames gazetteer with a manually crafted list of location abbreviations and codes to account for the incompleteness and mismatch challenges. Both Wikipedia and Google are mined to compile this list. They leveraged the ConceptMapper (Tanenblatt et al., 2010) to link locations (extracted from gazetteers) and use them to represent tweet tokens for the LMR task. Xu et al. (2019) assigned the BIO-like LMR prelabels that are predicted by a CRFs model to represent the tweet tokens alongside their distributed word and character representations. Note that crafting this type of features is equivalent to the *extraction* of candidate LMs phase in the gazetteer-based approaches (refer to section “[Gazetteer-based Approaches](#)”).

Entity features: This type of features is more general than the *Geographical features* in which the LMR models are fed with the NER tags extracted by NER models and their confidence scores (Nizzoli et al., 2020). In addition to that, some entity features are extracted from knowledge bases such as the DBpedia ontology class of the entity, the number of classes and superclasses of the entity, the node degree of the entity, and the length of the corresponding Wikipedia article in characters, among other features (Nizzoli et al., 2020).

Temporal features: The goal of these features is to capture common words based on chronology. Li and Sun (2014) manually complied a time-trend list of 36 common English verbs, auxiliary verbs, adjectives, or adverbs with scores of 1, 0, and –1 representing the future-, present-, and past-trends, respectively. These scores are then used to compute the time-trend score per tweet by averaging the scores of the tweet tokens occurring in the time-trend list.

Note that the Stanford NER tool employs a linear chain CRF model in its core (Finkel et al., 2005), hence all studies that leverage it are considered ML-based as long as their output is not interrogated by a gazetteer verification. The first employment of LM-based approaches for the LMR task is dated back to 2014 when Li and Sun (2014, 2017) developed their PETAR system. PETAR uses a linear-chain Conditional Random Fields (CRF) model. It is trained over features from all aforementioned feature categories. To overcome the mismatch issue in cases of informal abbreviations and misspellings, Li et al. applied the Brown clustering technique that groups tokens appearing in similar contexts. Concomitantly, Han et al. (2014) leveraged various lexical, semantic, syntactic, and geographical features on top of a CRF classifier to participate in the ALTA shared task (Molla & Karimi, 2014).

Takeaway Messages: Although CRF models accompanied by noisy gazetteers and a variety of hand-engineered features have achieved competitive performance in different studies (Han et al., 2014; Li & Sun, 2014, 2017; Molla & Karimi, 2014), their main limitation is the expensive feature-engineering phase, especially when developing the solutions for the emergency management domain.

Riding the Wave of Deep Learning Models

More recently, several studies proposed Deep Learning (DL) approaches. The first exploitation of DL approaches for LMR in the disaster management domain was proposed in 2019 by Kumar and Singh (2019). They trained a Convolutional Neural Network (CNN) model to learn tweets representation and perform the recognition. Xu et al. (2019) proposed DLocRL, a deep learning sequential pipeline for location recognition and disambiguation in tweets. For recognition, they employed the BiLSTM-CRF model that is fed with contextualized word- and character-level features concatenated with their geographical CRF prelabels. Following the same approach, Wang et al. (2020) proposed the NeuroTPR model that employs BiLSTM-CRF NER model (Lample et al., 2016) for recognition.

The employed Toponym Resolution systems by Wang and Hu (2019a) exploit neural-based BiLSTM recognition modules. The *DM_NLP* (Wang et al., 2019) recognizer learns character and word-level text features to represent documents. A CRF layer is added on top of the BiLSTM model. The model takes advantage of other syntactic features such as POS, StanfordNER, and chunking labels. It also uses contextual features that improved the performance of the model. Unlike *DM_NLP*, UniMelb (Lietal., 2019) BiLSTMbased model solely learns from world-level text representation. It differs in employing the self-attention mechanism. A binary softmax out layer is added on top of the BiLSTMbased model. The *UArizona* (Yadav et al., 2019) goes to the extreme and learns from concatenated word-, character-, and affix-level representations of text data. Akin to *DM_NLP*, a CRF layer is added on top of the BiLSTM model.

Suwaileh et al. (2020) reported the first results for the direct and simple employment of the BERT-based model in the LMR task under different transfer learning setups that account for the difference between the sources and target disaster events in terms of data domain, entity type, disaster domain, and geo-proximity. Later, Khanal et al. (2022) and Khanal et al. (2021) exploited the transform-based pre-trained models for the LMR task. Khanal and Caragea (2021) further pre-trained LUKE (Yamada et al., 2020) model on their data to learn contextualized entity embeddings that allow optimizing a self-attention mechanism for recognizing LMs. Khanal et al. (2021) investigated multi-task learning for different crisis management computational tasks, including LMR, key-phrase identification, eyewitness identification, and humanitarian categories classification. They empirically confirmed the positive impact of multi-task learning on LMR performance.

Diverging from others, Hu et al. (2022) introduced the GazPNE recognizer, an unsupervised model that fuses CNN and Bi-LSTM models to learn from around 4.6 M positive training examples extracted from gazetteers and 220 M negative synthesized examples. The advantage of GazPNE is that it does not require labeled examples for training.

Takeaway Messages: By now, we understand that the learning-based models show superior performance compared to other approaches as reported by the existing studies. With the plenty of existing DL approaches, there are yet many directions to explore, such as multitask learning, reinforcement learning, and adversarial

approaches, among others. The main disadvantage of the DL approaches is that they are data hungry. This unfavorable requirement has to be alleviated by building large-scale datasets and exploring the domain adaptation and transfer-learning techniques.

LMR Evaluation

A fair evaluation framework for the LMR task in the disaster domain has to provide diverse evaluation datasets, evaluation measures, and baseline LMR models. Unfortunately, the lack of a unified evaluation framework prevented comparing the methods we discussed in section “[Literature Review](#)” under fair conditions. Long-delayed, the first effort to provide a unified framework for the LMP task was the EUPEG framework (Wang & Hu, [2019b](#)) in 2019. EUPEG provides access to 5 non-disaster-specific LMP models and 8 general-purpose datasets. Only one of them is a Twitter dataset called Geo-Corpora (Wallgrün et al., [2018](#)). Surprisingly, the framework was used solely by Wang et al. ([2020](#)). Lately, Suwaileh et al. ([2023](#)) released the largest to date human- and automatically-labeled public and generalizable LMR datasets, alongside the evaluation script and benchmark results against representative the LMR task models.

This section discusses and compares the available evaluation datasets, the widely used evaluation measures for the LMR task, and the evaluation setups.

Datasets

Many Twitter disaster datasets are made available for the research community; however, a few are labeled for LMR. The construction of LMR datasets is an expensive task, as it requires human annotators to manually identify the locational spans in text, which is not a trivial task. Table 2 summarizes the existing LMR datasets Columns “#LMs (unique),” “Annotation,” “LM type,” and “Public” refer to the number of LMs in the dataset (and distinct LMs), the type of annotation, whether the LMs are annotated for location types, and whether the dataset is public..

There are several characteristics that most of the existing LMR datasets lack to possess to assure fair and practical evaluation Suwaileh et al. ([2023](#)) such as reasonable size, disaster domain coverage (to capture disaster-specific vocabulary), geographical coverage (to cover different location-naming conventions), temporal coverage (to include pre- and postdisaster periods), relevance and informativeness (to ensure quality and reliability of content), LM granularity coverage (to capture all types of location), and consistency and reliability in annotations.

Evaluation Measures

The standard evaluation measures for effectiveness of the LMR task are Accuracy (Acc), Precision (P), Recall (R), and F_β score that is the harmonic mean of Precision and Recall, per entity.

Nevertheless, the way these measures are computed is different from one study to another based on three main factors: (1) handling the *partial matches*, i.e., whether to reward the model when detecting part of the LM span; (2) evaluating

Table 2 Summary of the English disaster-related datasets

Dataset	# Tweets	# LMs (unique)	Annotation	Type	Pblc

“+D” indicates LMD datasets

per tweet or event, i.e., whether to report token-level macro or micro average performance; and (3) handling the *true negatives*, i.e., whether to reward the models when they correctly stay silent for a single tweet.

The partial matches are typically ignored from evaluation except in a few studies (Al-Olimat et al., 2018; Hu et al., 2022; Molla & Karimi, 2014). Molla and Karimi (2014) claim that they account for partial matches, but they do not elaborate on their strategy nor make their evaluation script public. Al-Olimat et al. (2018) penalize models by adding 0.5 to both false positive and false negative counts before computing the Precision and Recall. Hu et al. (2022) adopted the same evaluation guidelines as Al-Olimat et al., 2018.

Real Scenarios for Evaluation

Typically, the existing models are evaluated under an unrealistic assumption that labeled target data is available during the early stages of disaster events. As acquiring labeled data is costly during disasters, researchers should report the performance of their models under the zero-shot setup, where the model had never been introduced to training data from the target disaster. Therefore, studying the models’ generalizability under zero-shot learning is important while considering different factors such as disaster domain, geographical proximity, and language.

To investigate LMR model performance under these different scenarios, Suwaileh et al. (2020, 2022) explored the out-, in-, and cross-domain scenarios under the zero-shot condition using 5 disaster-specific datasets (Al-Olimat et al., 2018; Middleton et al., 2018). Their extensive experiments suggest that “target” evaluation setups show misleadingly high performance when compared to the more genuine scenarios, cross- and out-domain scenarios, during emergencies. Furthermore, they empirically

showed the importance of considering the domain (i.e., the disaster type) and the geographical proximity of the training and test data to improve the LMR models' performance. They also showed preliminary experiments that suggest training a multilingual model with little data from the target language is promising.

Above all, all the discussed studies in this chapter , except Suwaileh et al. (2023), are type-less recognition models, due to the lack of datasets that support the type-based recognition (Suwaileh et al., 2022).

Location Mention Disambiguation

This section starts with the formulation of the LMR task in section “[Task Formulation](#).” It then discusses the challenges associated with it in section “[LMD-Specific Challenges](#),” dives into different categories of proposed solutions in section “[Literature Review](#),” and finally presents the evaluation tools and their shortcoming in section “[Evaluation](#).”

Once the candidate location mentions are identified by the LMR system, the next step is to resolve them into actual locations that exist in a geo-positioning database (i.e., gazetteer); this task is known as Location Mention Disambiguation (LMD). The output of LMD models can be then used to pin LMs on the map using a geographical representation such as the standard *geographic coordinate system* (GCS) or the *geocode system*. The GCS is a spherical coordinate system that represents points on the earth using *longitude* and *latitude* angles measured with respect to the center of the earth. The geocode system represents geographical entities (points, lines, or polygons) using unique human-readable codes (or hashes) generated by dividing the geographic surface of the earth into grid cells at a multilevel hierarchy. Figure 5 illustrates the high-level overview of the LMD task, with the LMR task in context.

Task Formulation

To define the task formally, given the following inputs:

- A tweet t that is related to a disaster event e .
- A set of location mentions (LMs): $L_t = \{l_i; i \in [1, n_t]\}$ in the tweet t , where l_i is the i th location mention and n_t is the total number of location mentions in t , if any.
- A geo-positioning database (i.e., gazetteer) that consists of location profiles of toponyms: $P = \{p_i; i \in [1, k]\}$, where p_i is the i th location profile, and k is the number of location profiles that exist in G . Different gazetteers may contain different location properties such as the name (in different languages), alternative names (e.g., exonyms), geo-coordinates (latitude and longitude), hierarchical address, location type (e.g., city, street, POI, etc.), and other type-specific properties for different location types (e.g., “population” property for type “city”).

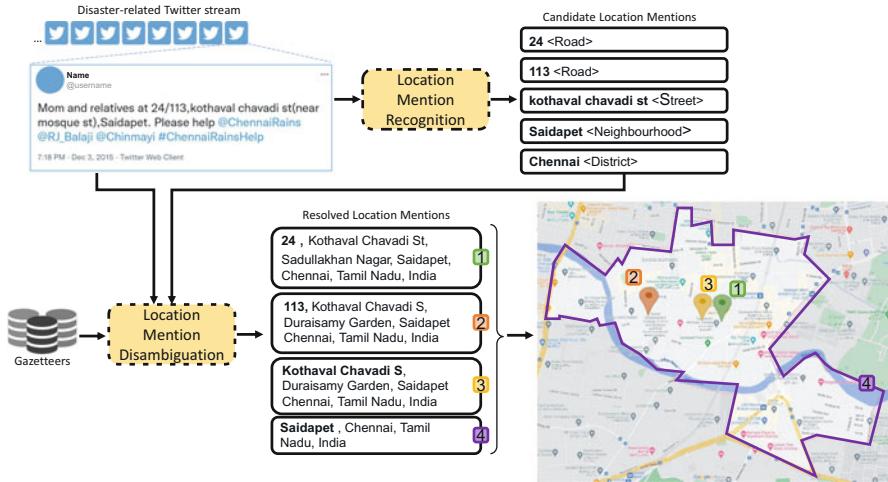

Fig. 5 High-level overview of the LMD task

The LMD system aims to match (or link) every location mention l_i in a tweet t to one of the location profiles p_i in G that correctly and accurately represent l_i , if it exists, otherwise it declares the location mention l_i as irresolvable (or unlinkable). The irresolvable LMs are usually due to the incompleteness of gazetteers as most of the existing digital gazetteers are crowdsourced.

LMD-Specific Challenges

Tackling the LMD task requires alleviating different challenges including:

Toponymic homonymy: The same location name might refer to different locations. For instance, “Doha” might refer to the “capital city of Qatar state” or the “Doha city in Kuwait.” Also, “Kuwait” could refer to the “State of Kuwait” the country, or the capital city “Kuwait” (different granularity). Additionally, at the finest-grained level, “Ooredoo” may refer to any branch of the telecommunications service provider inside, or outside Qatar.

Incompleteness: The existing digital gazetteers are constructed by the contribution of the community, crowdsourced. Hence, many of the locations, especially the fine-grained locations, might not appear in the gazetteers. In case the LMR system managed to detect such locations, the LMD system will not be able to resolve them.

Dynamism: The set of locations that exist in gazetteers are dynamic and do change over time as a consequence of multiple actions such as (i) changing the name (or properties) of a location (e.g., common with street names), (ii) deleting a location (e.g., permanently closing a restaurant), or (iii) building or opening a new facility (e.g., malls, airports, parks, etc.). This requires maintaining up-to-date gazetteers that log such changes to aid the LMD systems.

Large-scale multiclass problem: When perceiving the LMD as a classification task, it is converted into a large-scale multiclass problem in which the LMD system has to classify all l_i in G , in orders of millions, against the target LM l_i in tweet t . In this formulation, the LMD becomes more because of different issues such as class imbalance, data scarcity, and computational complexity.

Constructing a unified location database: Consolidating multiple gazetteers is a key to covering as many locations as possible with different properties into one unified gazetteer. Nevertheless, the merging and deduplication of toponyms is nontrivial task.

Literature Review

This section reviews the current solutions from the methodology perspective due to the absence of a unified evaluation framework that allows performance comparison between proposed solutions. There are a few studies that tackle the LMD task using machine learning and deep learning approaches. This chapter starts with a discussion on the hand-crafted and automatically computed features employed. It then presents presenting an overview of the existing approaches. Akin to the LMR systems, contextual features at character and word levels (e.g., learned by CNNs), syntactic features (e.g., POS tags), and geographical features (extracted from gazetteer attributes) are used. In addition to that, a few other features are proposed:

Contextual features: The gazetteer entries lack context to learn rich representations. Thus, external resources are used for expanding their representations such as Wikipedia articles. Articles could be used as a whole, or “in” segments.

Similarity features: These features are computed by the similarity of the candidate LMs that are extracted from tweets against the toponyms in gazetteers. The similarity is encoded using exact matching, substring matching (i.e., candidate LM partially matches a gazetteer toponym or the opposite), prefix matching (LM matching the beginning of a gazetteer toponym or the opposite), Jaccard similarity, or Levenshtein similarity.

Gazetteer features: The properties of toponyms in gazetteers are employed to capture relevance signals and prioritize gazetteer candidates. These features change according to the employed gazetteer. Different types of attributes are considered including the popularity of the toponym, the number of ancestor LMs, and the administrative division level, among others.

Mention neighbors features: The LMs often co-occur with their child or parent toponyms as illustrated in Fig. 1. This type of features takes advantage of this observation and uses all LMs in the tweet besides the target LM to be resolved. The relationship is encoded between the multilevel mention lists. They are also encoded by examining whether the gazetteer (i) toponym, (ii) the ancestor, or (iii) alternate names exist in the mention lists of the LM. The collective disambiguation considers the co-occurring LMs as features as discussed in section “[Collective Disambiguation](#).”

There are three commonly used English digital gazetteers as follows:

- Geonames: Geographical database covers all countries and contains over 11 M unique places (with 25 million different geographical names) that are available for download. The locations are categorized into nine main types (e.g., country, park, village, road, etc.) and also subcategorized into 645 feature codes.
- OpenStreetMap: An international street-level gazetteer that is constructed by a community of mappers. They continuously add and maintain data about streets, trails, and POIs around the entire world.
- Foursquare: A database with more than 105 M placenames that are collected using a collective crowdsourcing method. Specifically, they are collected by logging the users' check-ins from different platforms such as Twitter and Instagram.

Learning-Based Models

Middleton et al. (2018) trained an SVM model on gazetteer-based features including location type, population, and alternative names. Additionally, the disambiguation models of the toponym resolution system employed by Wang and Hu (2019a) are essentially machine learning models: (i) *DM_NLP* (Wang et al., 2019) is a Light Gradient Boosting Machine (LightGBM) model trained on similarity scores, contextual representations, gazetteer attributes, and mention list features; (ii) *UniMelb* (Li et al., 2019) is a Support Vector Machine (SVM) that uses different feature types such as the history results in the training dataset, population, gazetteer attributes, similarity, and mention neighbors features; and (iii) *UArizona* (Yadav et al., 2019) is a heuristic-based system that selects the toponym with the highest populations in gazetteers.

Deep Learning Models

Xu et al. (2019) proposed a novel attention-based two-pairs of bi-LSTMs trained for matching LMs against the Foursquare gazetteer. The Foursquare gazetteer constitutes a collection of location profiles. Each location profile (p) contains several attributes including title, category, address, tips, tips count, visitor count, visit count, and rating. To process the ps , the category attribute is represented in a one-hot vector, the word-based attributes are represented by averaging their TFIDF vector representations, and the numeric-based attributes are normalized using the global gazetteer counts. All these representations are concatenated before they are fed to the disambiguation model. On the other hand, tweet-LM pair are represented using their text-contextual representation, text-contextual representation attended to the p representation, and geographical distance. The two-pair networks learn the left (starting from the first token in the tweet and ending at the end of the LM) and right (starting from the LM and ending at the last token of the tweet) contexts of the LM. The geographical distance is measured using the Manhattan distance between the geo-coordinates of the user location, if available, and every p . Both representations then go through a fully connected layer to learn disambiguation.

Collective Disambiguation

To disambiguate LMs appearing in the same tweet, such as “Kuwait” and “Ooredoo,” one might expect that “Ooredoo” should be in “Kuwait” not in “Qatar.” The general approaches differ whether to resolve entities in isolation or using pair-wise strategy or in collective manner. Inspired by the pair-wise methods, Zhang and Gelernter (2014) consider the hierarchy of the location mentions in tweets when resolving them. Recently, Xu et al. (2019) collectively disambiguate all LMs in a tweet by adopting the Pair-Linking algorithm (Phan et al., 2017) that improved the disambiguation performance (accuracy).

Takeaway Messages: The LMD task is understudied for the disaster domain. A major challenge is the low performance of the LMR system that could negatively affect the LMD system. To mitigate this effect, sharing feedback between these two systems is a potential direction to explore.

Evaluation

Evaluating the LMD systems requires ground truth data of tweets containing the LMs and their corresponding entries from gazetteers. A non-gazetteer-specific dataset would contain the full addresses of the LMs allowing the LMD systems to freely choose their geo-positioning database.

Datasets

There is a dearth of Twitter disaster-specific LMD datasets. Only three datasets have been constructed and contain tweets in order of a few thousand. Table 2 presents the statistics of these datasets. Two of these datasets are available for the research community, namely, Middleton et al. (2014) and GeoCorpora (Wallgrün et al., 2018).

Middleton et al. (2018) evaluated their system using their own datasets (Middleton et al., 2014). Wang and Hu (2019a) evaluated it using eight different datasets available through EUPEG framework (Wang & Hu, 2019b), solely one of which is a tweet dataset that is GeoCorpora (Wallgrün et al., 2018) (refer to Table 2). Xu et al. (2019) used the dataset released by Ji et al. (2016).

Evaluation Measures

Similar to the LMR task, the Accuracy (Acc), Precision (P), Recall (R), and the F_β score are computed to evaluate the performance of LMD systems.

Additionally, the LMD systems are evaluated using geographical distance-based evaluation measures including the mean distance error (Mean DE), the median distance error (Median DE), and the distance-based accuracy (Acc@d), to quantify the distance between the predicted location and ground truth location in kilometers.

Furthermore, Karimzadeh (2016) proposed more evaluation measures that overcome the shortcoming of P, R, and F_β scores. While these measures evaluate binary classification tasks, the LMD task can be perceived as a multiclass classification task

that links toponyms in gazetteers against LMs in tweets; hence, these evaluation measures hence they are not the most applicable. Alternative measures assume that the LMD system output is a ranked list of toponyms extracted from gazetteers sorted by probabilities such as Cross Entropy (CE), Root Mean Square Error (RMSE), AND Eccentricity.

Challenges

Learning to predict the location mentions is a nontrivial task. LMP systems have to address many challenges that are generally related to the nature of the Twitter stream or related to the difficulty of recognition and disambiguation tasks.

Twitter Stream Challenges

Processing Twitter data entails accounting for various challenges that stem from the nature of the stream. This section discusses these challenges:

Tweet sparsity: Using solely the tweet text limited to a length of 280 characters to extract and resolve LMs leads to a lack of understanding of the context of the tweet.

Rapidly changing: The rapid linguistic and topical drift over the stream makes the LMP task more challenging. As a result, the commonly mentioned locations over the stream are easier to detect than the new and infrequent ones.

Hashtag riding: Once a hashtag attracted the attention of many users on Twitter, spammers use it to post irrelevant content with different intentions like advertising, self-promotion, propaganda, etc.

Noisiness: The noisiness of the stream causes a mismatch between the language used in tweets and the language used to create the gazetteers which are known as *Out of Vocabulary (OOV) issue*. Twitter users tend to use informal writing in contrast to other Web documents (e.g., news articles) that contain formal language. On the other hand, gazetteers are often constructed using formal names of locations. Below are example issues associated with the noisiness of the Twitter stream with example tweets from Table 3:

- **Nicknames:** Some places are known by different nicknames. In Tweet #1, *Chennai* is nicknamed “The Detroit of India” which does not exist in OSM gazetteer.
- **Capitalization:** Users tend to ignore capitalization when writing tweets (e.g., “chennai” instead of “Chennai” in Tweet #4).
- **Abbreviations:** Using short versions of the location names is common on Twitter, due to the restricted length of tweets, such as using “T. Nagar” instead of “Theagaraya Nagar” and “GM Chetty Road” instead of “Gopathi Narayanaswami Chetty” in Tweet #3.

Table 3 Example tweets from Chennai floods to illustrate the challenges of processing Twitter stream for LMP task

Tweet #	Tweet text	Problem
Tweet #1	#ChennaiFloods sad to see the state of city. <u>Detroit of India</u> is suffering. Hv personal experienced	Nickname
Tweet #2	Accommodation in t nagar to 30–50 people in Rameswaram road, <u>T. Nagar</u> . Contact 9843111199 #ChennaiRainsHelp #ChennaiFloods #chennaimicro	Capitalization
Tweet #3	Anyone around <u>T. Nagar</u> , needing shelter or food, can approach the Gurudwara on <u>GM Chetty road</u> #Chennai	Abbreviations
Tweet #4	Medical students of <u>shri</u> ramchandra medical college in chennai stranded without supplies. Need help.	Misspelling
Tweet #5	sm 1 help providing water 50 children <u>@Lawrence Charitable Trust</u> .safe.2/4, <u>1st cross st</u> , 3rd avenue,AshokNagar-LakshmanSruti #ChennaiFloods	Shortcuts: “st” and “@”

- **Misspelling:** Incorrect spelling and grammar mistakes are common in tweets; hence, LMs could be also misspelled such as “shri ramchandra medical college” that should be corrected to “sri ramchandra medical college” in Tweet #4.
- **Shortcuts:** In Tweet #5, the wrote used shortcuts (e.g., st and Rd. instead of street and road, respectively) and symbols instead of prepositions (e.g., “@” instead of “at”).

Task-Specific Challenges

In this subsection, we discuss the challenges related to tackling the LMP task generally and during crisis scenarios.

Time-criticality of solutions: Empirically effective solutions are not necessarily ready for efficient deployment at the onset of disaster events. Therefore, the developed systems must be trained and evaluated to run in real-time to enable effective crisis management.

Scarcity of LMD labeled data: Supervised learning algorithms need a huge amount of representative data to perform effectively. However, acquiring training datasets is critical when systems must be trained and deployed promptly *in real time* for disaster management because acquiring labeled data slows down the process greatly. There are a couple of existing LMD datasets with size in order of a few thousands.

Future Directions

There are several directions for future work, including:

LMP problem modeling: In pipeline architecture, the performance of the disambiguation system depends greatly on the recognition system. Inaccurate candidate

location mentions affect negatively the LMD system performance as it would fail to match potential locations from the knowledge base of locations. Hence, joint solutions allow the two systems to pass feedback to each other and optimize accordingly. This direction was explored for the LMP systems outside the disaster domain (Ji et al., 2016).

Technical considerations: First, the Twitter stream challenges need further exploration such as researching potential techniques to (1) enrich the tweet representation, (2) mitigate the effect of lack of labeled data at the onset of a disaster event, among other challenges. Second, the social networks (e.g., following networks and interaction networks) are neglected in LMP studies. Hence, utilizing social signals is an important aspect to explore its effect on the performance of the LMP. Last but not least, the key bottleneck of gazetteer-based LMR solutions and LMD systems is the choice of geo-positioning databases. There is a large room for contribution regarding augmentation, aggregation, and maintaining up-to-date geo-positioning databases.

Evaluation: There is a persistent need for improving the evaluation strategies for LMP tasks. For LMR evaluation, in almost all existing studies, the evaluation is limited to exact matches with gold annotations. The studies that focus on partial matches are heuristics-based. Further exploration on best practices for evaluating partial matches is required. For LMD evaluation, proper ways to tune the distance threshold in the distance-retrieval-based evaluation measures is worth investigation.

Deployment in real scenarios: The existing LMP systems are rarely deployed by response authorities (Reuter, 2015; Reuter et al., 2018) due to various issues, for example, the lack of analysis in real-time settings. Analyzing efficiency is overlooked in most of the existing studies, and the focus is mostly on effectiveness albeit some studies account for efficiency when designing the systems.

Other issues include the unreliability of information from social media and the lack of readiness of solutions to be customized for the needs of different stakeholders, to list a few. Recent studies have attempted bridging the gap between technologists and relief organizations by understanding their needs (Hiltz et al., 2020) and the utility of existing solutions (Zade et al., 2018).

Conclusion

This chapter sheds light on the importance of geolocation information for the response authorities in the domain of disaster management. It discusses the geolocation information requirements of different stakeholders and links them to the existing computational tasks. The discussion highlights the recent trends for proposed solutions from technical perspective, including their strengths and shortcomings, then shapes potential future directions to address the limitations and meet the requirements of stakeholders.

Abstract

Working on countermeasures to reduce floods and respond quickly is vital for ensuring fatalities are reduced to a minimum. Remote sensing can provide an adequate amount of information for flood management systems. Techniques from several disciplines, considering image processing, remote sensing, machine learning, and data analysis, have been investigated in the literature to manage various flood management duties. Despite the growing number of research articles outlining the application of numerous computer vision techniques in the field of remote sensing applications, there exists a dire need for a complete analysis of these technologies from the standpoint of flood management. This chapter aims to fulfill this need by providing a comprehensive review of the literature covering all aspects of remote sensing applications for flood management including flood detection, flood delineation of affected areas, and damage assessment. The review is organized to cover both traditional and deep learning methods as well as the open-source datasets used in the relevant studies.

In addition, the chapter investigates existing products and services that currently provide usable insights about past or ongoing flood disasters to emergency response operations. Finally, the chapter highlights the challenges and future areas of research in flood management.

Keywords

Flood mapping · Flood monitoring · Remote sensing

Introduction

Floods are one of the widely occurring and expensive natural disasters. As a result of global climate variation consequences, more persistent and intense precipitation is projected to further boost the severity of floods (Mason et al., 2021a). Floods, according to a report published by the “United Nations Office for Disaster Risk Reduction (UNDRR)” (UN Office for Disaster Risk Reduction, 2020), were the most prevalent type of disaster in the last two decades, affecting the greatest number of people. Floods are a persistent threat to both developed and developing countries. The increasing number of flood incidents around the world requires the identification of appropriate flood management strategies. Various global organizations like Red Cross, European Commission, UN Office for Disaster Risk Reduction (UNDRR), and UN Climate Technology Center and Network (UNCTCN) are working independently or in collaboration for minimizing the impact of floods on human lives. It is critical to comprehend how flood susceptibility can be precisely measured and mapped to aid emergency responders. Thus, both preventive and emergency actions are required to minimize the possible impact of floods on human lives and property. According to a report by UNCTCN, flood mapping predominantly looks at the anticipated extent and depth of flooding in a designated location, based on a number of scenarios. Utilizing these flood maps, necessary measures can be taken to enhance preparedness like alterations in land-use planning, execution of particular flood-proofing measures, establishing emergency response plans, etc.

The stakeholders have specific requirements for the map’s content, scale, accuracy, and readability based on the particular objective. According to “European Exchange Circle on Flood Mapping (EXCIMAP),” flood plain maps reflect the geographical locations which could be affected by flood water (excluding sewerage system) (Anonymous, 2007). Various stakeholders have different use cases for flood maps. The stakeholders have specific requirements for the map’s content, scale, accuracy, and readability based on the particular objective. Considering diverse use cases, flood maps can be utilized for:

- Monitoring of floods
- Risk management strategies for flood prevention and mitigation
- Land-use planning and land management
- Planning emergency response

- Raising public awareness
- Insurance sector (private sector)

In recent years, advancements in technologies have altered the way the world works. The field of disaster management, like any other, is increasingly leaning toward the use of modern technologies. During a flood event, satellite-based flood inundation mapping becomes more and more important for emergency responders. In addition to helping crisis managers with flood monitoring, management, and reaction during a disaster, it also provides better situational awareness by highlighting the areas that call for immediate action. Remotely sensed flood mapping can also help to identify flood-affected areas which may go undetected due to large geographical areas and thus can cause a delay in immediate relief response activities (Ahmad & Afzal, 2019). Not only, remote sensing is commonly used to map the information about the flood water, but it can also be used to assess the impact caused by floods. For this purpose, spatial and temporal aspects of high-resolution satellite imagery are acquired before and after the flood event to compare the prior situation with the post-event situation.

Most of the literature is focused on utilizing remote sensing technologies for a specific study area, hence, limiting the scope of generalization and overall global impact of flooding (Brema, 2020; Borah et al., 2018; Das, 2018; Zhang et al., 2016; Feng et al., 2015; Haq et al., 2012; Scotti et al., 2020; Syifa et al., 2019; D'Addabbo et al., 2016b).

As the flooding phenomenon is a highly random process and the rate of retrieving images via satellites is pretty slow itself, such local implementation is nonetheless constrained by a number of restrictions. There are issues with exclusively employing remotely sensed images to analyze, capture, and comprehend the full scope of flood monitoring (Syifa et al., 2019); this limitation led to the area of research where multiple sources are integrated together for enhanced flood mapping (Sadiq et al., 2022). Additionally, flooding is known to significantly destroy highly valuable infrastructure, like bridges, roads, and the communications network, making it challenging to evacuate those trapped in flooded regions. As per the report of *Financial Management of Flood Risk* published by the “Organization for Economic Cooperation and Development” on flood-related economic loss in the year 2016 (OECD, 2016), roughly 40 billion US dollars were lost owing to floods in different areas of the world. Destruction of communication setup during floods can severely affect map generation, thus resulting in delayed risk management and rescue operations (Watik & Jaelani, 2019). The majority of existing literature covering remote sensing for flood mapping focuses on one or very limited aspects and does not provide a comprehensive review covering the broader spectrum of remote sensing in flood mapping. (Munawar et al., 2021) recently presented a review on flood management covering only the literature related to image processing and machine learning. Similarly, (Iqbal et al., 2021) reviewed only the literature from the aspect of computer vision techniques associated with successive flood management phases. Literature covering the area of remote sensing for damage assessment was reviewed by (Rahman & Di, 2020). Still, their study was only limited to flood crop loss

assessment, whereas (O’Hara et al., 2019) considered just one case study of Ireland to provide the review of the agricultural impact of flooding. Their study was also limited to Sentinel-1 analysis. (Sharma et al., 2019) provided a limited review of flooding in Nepal at the regional level and compared it with the global context. Similarly, (Shivaprasad Sharma & Roy, 2017) only focused on remote sensing for flood management in the area of Kopili river basin, Assam, India. (Teng et al., 2017; Rahman et al., 2017) reviewed the use of remote sensing in flood management, where (Teng et al., 2017) considered the advances in remote sensing for the assessment of flood hazards, susceptibility, exposure, risk, early warning system, damage assessment, and planning for risk mitigation, whereas (Rahman et al., 2017) provided an empirical analysis of software capable of modeling flood inundation. Although (Shen et al., 2019) provided a detailed review of SAR-based studies for flood inundation and extent mapping, their study lacks the literature on optical imagery for flood mapping. Earlier reviews are either limited to fixing geographical locations or targeted the limited scope of remote sensing of flood management.

This study focuses on covering the gaps mentioned in previous studies by reviewing major aspects of remote sensing for flood mapping and monitoring. Especially, for early-stage researchers and practitioners, it is critical to have a systematic review of existing literature on the significance of remote sensing for flood mapping and monitoring. Therefore, the first aim of this study is to provide a comprehensive review of the literature covering major aspects of remote sensing for flood management ranging from flood detection, mapping, and damage assessment. This study also aims on reviewing the literature covering traditional and machine learning methods along with a detailed overview of any open-source datasets related to the corresponding studies. Another aspect of this study is to list down the systems, repositories, and services that currently exist to provide usable insights about an ongoing flood disaster to emergency response operations by analyzing the remote sensing data.

The flow of the rest of the chapter is arranged as follows. Section “[Methodology](#)” enlists the details on the methodology used to select, screen, and review papers used in this study. Section “[Remote Sensing for Flood Mapping](#)” presents the role of remote sensing in flood mapping, followed by the remote sensing in flood monitoring in section “[Remote Sensing for Flood Monitoring](#)” and conclusion and future directions in section “[Conclusion](#).”

Methodology

The main objective of this research is to conduct a thorough and methodical analysis of the recent state-of-the-art remote sensing technologies extensively used for flood monitoring and mapping in order to identify any current limitations. In this context, a detailed review of the literature in the remote sensing domain was conducted in order to discover new developments in flood monitoring and mapping. To accomplish these aforementioned objectives, a data repository of relevant, up-to-date, and authentic research papers published in top-tier journals was compiled.

Paper Selection Criteria

Initially, in the search process to gather articles for this research work, Google Scholar and Scopus search engines were preferred. The article search was done in two major phases: article retrieval and screening phases. Later, the search engine's queries were constructed to fetch the articles. The search queries were created using keywords associated with flood mapping using remote sensing which include “remote sensing” AND “flood mapping,” “satellite imagery OR satellite image” AND “flood mapping,” “remote sensing” AND “flood monitoring” AND “Damage assessment,” “remote sensing” AND “flood mapping” AND “deep learning OR machine learning,” and “remote sensing” OR “satellite image” AND “flood mapping” AND “change detection.” Using all these keywords, total of 986 research articles were fetched. During the first screening phase, a set of filtering options were used to ensure the papers belonged to the (1) final publication stage, (2) article or book chapter, (3) articles published after 2010, and (4) articles published in the English language which were included in this review. These filtered articles were then processed to remove any duplicates, reducing the number of articles to 365. After screening and duplicate removal, articles were manually filtered to remove irrelevant ones. The manual screening was performed based on the following:

1. Articles only using remote sensing as an auxiliary task are excluded.
2. Articles focused on flood prediction are excluded.
3. Articles focused on flood risk assessment are excluded.
4. Articles focused on flood analysis from sources other than remote sensing are excluded.

The manual screening reduced the article's number to 70, which were then reviewed in detail for this chapter. Figure 1 provides an overview of the search and selection criteria.

Remote Sensing for Flood Mapping

Floods are a natural phenomenon that can practically occur anywhere. Although river and coastal floods are two of the most prevalent forms, floods may not even occur near a body of water. Flood damage can be caused by heavy rainfall, inadequate drainage, and even nearby dam construction projects. Wide-scale flood mapping is used to determine the extent of a flood or inland inundation, as well as the impacted infrastructure, such as roads and settlements, and impaired regions of interest, such as agricultural fields, as part of an emergency response. Disaster management authorities and other stakeholders can use the flood mapping information to conduct rescue operations in affected areas, as well as coordinate appropriate recovery actions and preventive measures for any future catastrophes. Remote sensing technologies which provide a unique source of data for the application can currently be used to assess the devastating effects of flooding (Bresciani et al., 2011).

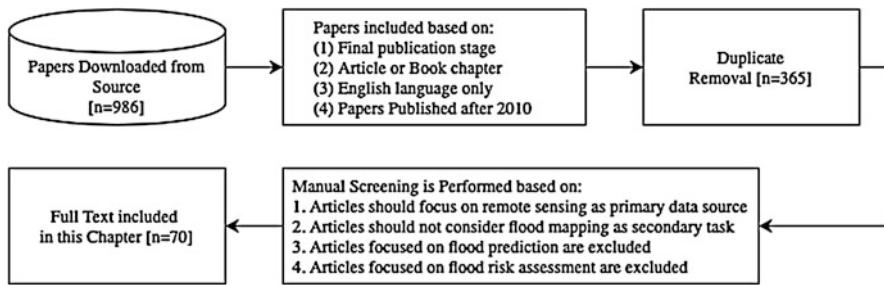

Fig. 1 Paper selection criteria

Remote sensing is one of the most extensively utilized platforms for disaster management and extended area mapping. *Sentinel-1*, *Sentinel-2*, *Landsat 8*, *Dove*, and *WorldView* are a few examples of medium- to high-resolution satellite imagery that can offer a lot of important data for locating and extracting flood-affected regions, evaluating the damage (such as to infrastructures like roads and bridges), and feeding information to models that can determine how much flooding occurs in inland and coastal locations. For inundation mapping, both synthetic aperture radar and optical sensors can be utilized, with varying levels of precision, capacity, and terrain difficulty. Water surfaces can be quickly and precisely extracted from optical remote sensing data using water indices. As new satellites (like *Sentinel-2* and *Landsat 9*) and long-term fine-resolution satellite data (like *Landsat* data) are being launched and operational, optical remote sensing techniques are significantly assisting in the global and regional water delineation. However, clouds and overcast weather, which are typical during flood occurrences, reduce the validity of optical readings, whereas synthetic aperture radar (SAR)-based remote sensing techniques penetrate the atmosphere well and can thus provide more accurate measurements. SAR can map flooding at high to very high and detailed resolution (from 30 m to 1 m) under practically any weather situation by identifying the scattering process. SAR can also operate at night as an active sensor. SAR data retrieval techniques are more difficult to develop than optical sensor technologies, and fully automated systems that don't require any human involvement at all are still unusual. SAR also suffers from noise in the reflected signals, and it is a challenging task in itself to clean the SAR imagery for further processing (Table 1).

Synthetic Aperture Radar Imagery for Flood Mapping

SAR data dependability is growing quickly as remote sensing data availability increases and new state-of-the-art processing techniques are being developed. *TerraSAR-X*, *ALOS-2/PALSAR-2*, *COSMO-SkyMed*, *RADARSAT-2*, and *ICEYE* constellations are now among numerous very high-resolution (VHR) SARs capable of detecting urban flooding with a spatial resolution of 3 m or more. The medium-high-

resolution Sentinel-1 is delivering open access to freely available satellite data in near real time obtained on a predetermined schedule, making it particularly appealing for flood-related studies.

Due to different backscattering characteristics, several forms of land cover must be taken into account for SAR-based flood mapping:

- Open water or river flooding, where parts of the land or bare vegetation are completely submerged
- Urban flooding, where buildings and other infrastructure are partially/fully submerged in flood water but the majority of the structures remain above water but suffer high damage
- Vegetation area flooding, forest or under vegetation flooding

Automated flood detection in rural or riverine areas has been the subject of extensive research (D'Addabbo et al., 2016b; Pulvirenti et al., 2011a, b; Martinis et al., 2015; Twele et al., 2016; Matgen et al., 2011; Giustarini et al., 2012). The majority of studies has been using traditional techniques, including thresholding and change in backscatter intensities between the SAR images captured before and after the flood. (Pulvirenti et al., 2011a) computed the threshold values between water and land pixels by using Otsu thresholding, whereas (Matgen et al., 2011) applied a nonlinear fitting approach for thresholding, while assuming a gamma distribution. (Tamkuwan et al., 2021) applied change detection over the imagery from *ALOS-2* and *Sentinel-1* satellites to detect flooded areas from the flood events in Nakhon Phanom province, Thailand. Flood detection in the open landscape areas was recently explored by (Hlaváčová et al., 2021). They proposed an automatic flood detection system that combined histogram thresholding with multi-temporal change detection techniques for open-water identification. Integrating remote sensing and geographic information system (GIS) for assessment of crops damaged due to the flood was proposed by (Banerjee & Pandey, 2019). Fuzzy logic over high-resolution imagery from TerraSAR-X for generating flood segmentation maps was also very popular and employed by many researchers during the last decade (Pulvirenti et al., 2011b; Martinis et al., 2015; Twele et al., 2016), where (Martinis et al., 2015) developed an open-source full pipeline including SAR data preprocessing, classification model's initialization followed by a post-classification, and processing by fuzzy logic-based approach. Their service can be triggered automatically through an online service but only after satellite data delivery is done. For emergency response purposes, the service can also be activated on demand (Table 2).

Several organizations, including the “Copernicus Emergency Management Service (EMS),” have developed semiautomatic flood extent extraction methods using SAR images. These systems operate relatively better in rural regions but perform poorly in the majority of highly urbanized or densely populated areas. Due to radar shadowing and latency caused by structures, urban flood detection is problematic because certain portions of the urban ground surface could not be visible to the SAR. The dry shadows, in particular, appear to be identical to most water regions in SAR imaging and could be misclassified as water. Most of the previous studies follow the

Table 2 List of satellites available for flood mapping – Paid* indicates that the source is paid but provides constrained resources for free

approach of utilizing Sentinel-1 SAR imagery for flood mapping of urban areas using change detection algorithms requiring pre-flooded and post-flooded images from areas of interest. (Giustarini et al., 2012) used a change detection method over very high-resolution SAR imagery from TerraSAR-X to accurately map flooding in the urban areas during the 2007 Severn River flood (UK). Recently, (Ulloa et al., 2022) proposed incorporating the spatial signatures for the change detection along with deep convolutional long short-term memory for time series analysis of satellite data to efficiently map flooding in urban areas. (Chini et al., 2019) proposed a two-stage technique using Sentinel-1 data of Hurricane Harvey in Houston, Texas. (Li et al., 2019) employed a Bayesian network to construct an unsupervised classification method for flood detection in urban areas by combining interferometric coherence and SAR intensity. (Jiang et al., 2021) used unsupervised deep learning models over Sentinel-1 imagery for flood mapping. They were able to estimate the damages to various land cover types by superimposing a worldwide land cover map on top of it. (Lin et al., 2019) used a Bayesian framework to do a time series analysis of Sentinel-1 SAR imagery for urban flood detection. With the recent advancements in deep learning technologies, many researchers have used modern deep learning architectures in their studies of flood mapping. But, these supervised deep learning

methods rely heavily on annotated data sources. Recently, (Bonafilia et al., 2020) released a dataset *Sen1FloodII* which is publicly available for remote sensing community to develop deep learning-based solutions for flood segmentation task. The details of the dataset can be found in Table 3. *NASA Interagency Implementation and Advanced Concepts Team* in collaboration with the “IEEE GRSS Earth Science

Informatics Technical Committee” launched a flood detection contest. Participants were given the task to develop appropriate approaches that can delineate open-water flood areas and identify flood extents from SAR imagery, which occurs frequently throughout the world. The details of the dataset released with the contest can be found in Table 3. (Paul & Ganju, 2021) proposed an ensemble-based unsupervised deep learning approach to generate the flood segmentation masks. (Yang et al., 2021) compiled a high-resolution (10 m) flood inundation dataset across the “contiguous United States (CONUS)” using data from almost the full Sentinel-1 SAR collection. Additionally, they connected their information to the “Dartmouth Flood Observatory (DFO) Global Active Archive of Large Flood Events database” (Robert Brakenridge, 2010).

Optical Imagery for Flood Mapping

Optical satellites operate by recording the electromagnetic energy and rely upon the sun’s illumination, or thermal radiation is reflected from the earth’s surface to generate the image values that are observed by the sensor. This generates natural-looking visuals, easily perceived by human eyes. Due to higher bandwidth and larger spectral channels, optical sensors can produce high-resolution images that can be further used for many applications. The remote sensing community has also been using optical imagery for flood mapping.

The availability of “Landsat/ERTS-1 and Sentinel-2” data allowed scientists to develop the algorithms to quantify land cover changes over time, starting with the Normalized Difference Water Index (NDWI) (Myneni et al., 1995). This work laid the foundation for later researchers to develop similar spectral indices focusing solely on water mapping such as the “Normalized Difference Water Index (NDWI)” (Gao, 1996; Ety et al., 2021; Yovan Felix & Sasipraba, 2021; Solovey, 2019; Munasinghe et al., 2018; Bangira et al., 2017) and “Modified Normalized Difference Water Index (MNDWI)” (Hanqiu, 2006; Li et al., 2021; Sajjad et al., 2020; Solovey, 2019; Munasinghe et al., 2018; Bangira et al., 2017). Recently, (Solovey, 2020) used Sentinel-2 spectral indexes for flooded wetland mapping. Like any other field, machine learning is also used in flood mapping using optical imagery (Syifa et al., 2019; Zhang et al., 2021; Mateo-Garcia et al., 2021; Bai et al., 2021). (Akiva et al., 2021) proposed a self-supervised flood segmentation network *H2O-Net*, where the model was trained on low-resolution Sentinel-2 imagery to generate the NIR band for high-resolution images from PlanetScope for generating better flood segmentation maps.

A recent study focused on urban areas (Peng et al., 2020) proposed a self-supervised learning framework leveraging multi-temporal optical imagery for patch-wise urban flood mapping. Their approach works by analyzing change vectors with patch features learned via a self-supervised autoencoder to generate patches of potentially flood-affected areas. MediaEval 2019 also launched a subtask “city-centered satellite sequences (CCSS)” of the multimedia satellite task. Participants approached the problem using both change detection, deep learning, and hybrid

approaches combining change detection with deep learning (Jain et al., 2019). Recently, (Mateo-Garcia et al., 2021) collected Sentinel-2 imagery for all the flood events between 2016 and 2019 from Copernicus hub and released a dataset *WorldFloods* covering most of the world surface areas. Using the dataset, they also developed a deep learning model for flood segmentation. While most high-resolution imagery is not free, MAXAR and PlanetLab do provide limited high-resolution imagery for research purposes (users need to get approved). Using the high-resolution Planet imagery collected during Hurricane Harvey, (Peng et al., 2019) developed a deep learning model that can take the advantage of bitemporal optical imagery to generate detailed flood segmentation masks. In small- to medium-scale project areas, UAVs are rapidly being acknowledged as an effective tool for gathering data that is critical for flood mapping research. The imagery gathered by UAVs may be used to create detailed flood maps and digital elevation models (DEMs). The data provided by UAVs are more accurate and geo-referenced and have greater resolutions than most publicly available data. This information may be used with FEMA floodplain maps to determine the most appropriate and cost-effective flood control measures for a given town. (Rahnemoonfar et al., 2021) gathered a high-resolution aerial imagery dataset *FloodNet* that shows the damage the impacted areas sustained after the flooding. The dataset was collected after the event of Hurricane Harvey.

Hybrid Satellite Imagery for Flood Mapping

Both SAR and optical imagery come with some limitations, e.g., optical imagery is not immune to the weather conditions like clouds and haze; thus a high cloud percentage on any given day can hamper the performance of any modeling technique using optical imagery. Similarly, SAR imagery is not directly generated by the sensor in a human-understandable form; the reflected microwave signals undergo extensive and complex preprocessing to lay out a perceivable representation of the objects in the area of interest, thus making the whole process expensive and prone to errors. However, cooperation between the SAR and optical imagery has been employed successfully in recent years thanks to significant developments and the frequent availability of multi-sensor data. Recently, (Notti et al., 2018) provided an overview of the shortcomings of independent satellite sources for flood mapping and proposed a multisource method. They combined SAR, multispectral imaging, DEMs, manual mapping, and auxiliary data such as field measurements, civil protection reports, geolocated images, or news articles found on credible websites to generate quality flood maps. (Bai et al., 2021) fused the SAR data from medium-resolution Sentinel-1 and optical imagery of Sentinel-2 to enhance the flood mapping. They demonstrated their deep learning-based approach on Sen1Flood11 (Bonafilia et al., 2020) dataset. A similar approach for data fusion of high-resolution imagery of SAR (“COSMO-SkyMed strip map” at 3 m resolution) and optical (“RapidEye” at 5 m resolution)

was proposed by (D'Addabbo et al., 2016a). They utilized the Bayesian network approach for data fusion and compared the findings with models from independent sources to prove the superiority of the fusion technique. (Ohki et al., 2020) combined the hydrodynamic flood simulation data by TE and SAR data from ALOS-2 for flood mapping of urban areas. (Elkhrachy et al., 2021) generated flood hazard maps by combining the thresholding method applied on Sentinel-1 imagery, velocities, and depth obtained from HEC-RAS 2D simulation data. Recently (Gašparović & Klobučar, 2021) used a multimodal approach, where they used Sentinel-1 and Sentinel-2 data to generate the flood segmentation maps. To further improve the accuracy of obtained results, they incorporated geographic information system (GIS) layers, habitat maps, and flood hazard maps as additional sources of information. During Hurricane Irene and Schoharie Creek floods, (Renschler & Wang, 2017) performed multisource data fusion (GIS, hydraulic model HEC-RAS, and airborne LiDAR data) and modeling to assess and communicate complex flood dynamics for supporting better decision-making. Urban flooding can be detected using the change detection approach (Mason et al., 2021a), which uses Sentinel-1 and the WorldDEM DSM, albeit it may not be as precise as utilizing VHR SAR and LiDAR. Urban flooding is a major problem for SAR imagery as well as optical imagery; (Mason et al., 2021b) combined flood maps of the urban area with SAR backscattering signals with adjacent digital surface models to yield a high detection accuracy. Their approach worked well in both rural and urban areas than SAR-based mapping alone. Similarly, (Sadiq et al., 2022) proposed to utilize the flood maps generated from SAR imagery and social media content from Twitter to provide more informed flood maps for both urban and coastal areas. They also compared the generalization capabilities of deep learning vs the thresholding method for flood mapping. Remote sensing has been comprehensively used for the assessment of financial damages caused by flooding. (Psomiadis et al., 2019) used Landsat 7 and Sentinel-1 for flood mapping and Sentinel-2 for land cover. Combined with the elevation data, they were able to map the affected cultivations with high precision and the financial effects of flooding.

Remote Sensing for Flood Monitoring

Flooding can happen anytime and anywhere; even the developed nations are hardly immune, and it costs dozens of lives and billions of dollars. But, with constant monitoring and assessment, the impact of flooding can be reduced. Flood monitoring can be divided into multiple phases of flooding:

- Planning: This step involves educating people, building infrastructure less likely to be damaged by flooding, and planning measures to reduce the impact of flooding.
- Risk assessment: Methods involving the identification of vulnerable areas and population.

- Early warning system: The set of capacities needed to generate and disperse timely and resourceful warning information to individuals, communities, and organizations to prepare and act appropriately in sufficient time to reduce the possibility of loss (UNDRR 2009).
- Flood extent mapping: Segmenting flooded areas in a satellite imagery.
- Flood hazard mapping: Identification of flood risk areas and level of damage shown on the map.
- Damage assessment: Methods involving the estimation of economic and noneconomic damages caused by flooding.

Flood monitoring is a continuous process that generally spans various stages of flood and also during normal days where the planning, prediction, vulnerability, and risk assessment occur, followed by early warning systems before the flooding. Mapping and damage assessment are performed during and post-flooding. While flood prediction, early warning systems, and vulnerability assessment are crucial for many practitioners and researchers, they are not in the scope of this study; thus, we considered the role of remote sensing for flood monitoring in the mapping and damage assessment part only. Different approaches have been employed in the literature to perform the flood monitoring task. Recently, (Hlaváčová et al., 2021) performed the multi-temporal analysis of Sentinel-1 imagery for open-water flood detection and monitoring. Similarly, (Ulloa et al., 2022) also focused on performing the spatiotemporal analysis of Sentinel-1 imagery using convolutional neural networks. By combining Landsat 8 optical imagery and COSMO-SkyMed radar imagery, a new strategy for flood monitoring was proposed by (Tong et al., 2018). For water extent determination in the periods before and during the flood, they applied a support vector machine and an active contour without edges model. Combining multiple source satellite datasets, including the Gaofen (GF) series and Zhuhai-1 hyperspectral, (Zhang & Xia, 2021) used a mix of machine learning and thresholding techniques for flood monitoring. Their proposed method not only could detect the water extent but also could estimate the flood course during the flood. (Refice et al., 2020) integrated different bands of SAR imagery for detailed flood monitoring of remote vegetated land.

Satellite data can help with flood mapping, near-real-time monitoring, and damage assessments, which are often complemented by in situ data and physical models. However, the variety of supporting data available, along with the varying demands of authorities, first responders, and academicians, makes it challenging to be aware of all accessible information. We list down the number of freely accessible as well as interactive web mapping tools that throw light on flood management from a variety of viewpoints in order to acquire a better understanding. Table 3 provides the list of all the available flood monitoring systems along with their links. Similarly, Table 2 lists down all the satellites that can possibly be used in flood monitoring from various perspectives. While some of these can be obtained free of charge, others require a paid subscription to download the imagery.

Conclusion

This study categorizes the remote sensing technologies adopted for flood mapping and monitoring into radar, optical, and hybrid. We classified these studies based on the locales (urban/rural), methodology, and data sources used by the authors after doing a thorough content analysis of each study article's flood mapping approaches. For example, change detection, indexing, and thresholding approaches for flood mapping have been widely used in the literature and have proven to be the most effective in rural areas, whereas machine learning-based methods are more suited to urbanized areas. The difference between machine learning-based methods and traditional thresholding/thresholding/indexing methods is that generally supervised machine learning methods are driven by a huge amount of specific (annotated) data to generate plausible results, whereas numerical models are not dynamic and rely on a predefined set of mappings, calculations, and equations, implying that flood-related knowledge has already been fed to them by human experts. SAR and optical data have been extensively used in literature for flood mapping in rural as well as urban areas, but using hybrid data sources provides a more informed decision for different terrain types. We also conclude that, although the SAR data has been dominant by constituting 40% of the overall literature since 2010, the use of the hybrid approach is currently gaining rapid interest in the remote sensing community and becoming the major approach for recent studies. Since 2018, 51% of the flood monitoring literature reported better performance using hybrid approaches. Machine learning approaches effectively control the uncertainties associated with natural disasters like floods. The constraints of machine learning algorithms may be overcome by giving the model appropriate historical flood data and flood inventory maps. Machine learning models provide a time- and cost-efficient technique to track several aspects of floods. The considerable annotation required by supervised machine learning techniques can be reduced by using semi-supervised deep learning methodologies. Machine learning algorithms can effectively analyze and extract features from unstructured data. There is still a scarcity of high-quality accurately annotated datasets for flood mapping that has yet to be addressed. For flood mapping, deep learning models tailored explicitly to flood dynamics have neither been thoroughly experimented with nor properly documented. Therefore, more research into this area is required. This may be accomplished by obtaining data from a variety of sources, including disaster history, satellite imagery, social media, and geographic information systems (GIS). The collected data may be utilized to train the deep learning system. Currently, remote sensing-based approaches are used with specific types of satellite imagery and these approaches fail to perform well when exposed to the data gathered from a different sensor/satellite. This opens a new area of research and a need for a consolidated system with the capability to process the data from variable sources. Another possible future direction can be to enhance the resolution of low- to medium-resolution satellite data for a better flood mapping system.

Acknowledgments This chapter was made possible by BFC grant #BFC03-0630-190011 from the Qatar National Research Fund (a member of the Qatar Foundation). Abstract

Managing disaster is a major challenge with often untenable cascading effects to many countries, geographically collated regions, states, districts, and local areas with vulnerable population, infrastructure, and economies. Today substantial quantity of data is received via various sensors, including smart phones, satellites, social media, the internet of things (IoT), LoRA (long range) radio communication, LiDAR (Light Detection And Ranging), HAM radio, Global Navigation Satellite System, and various on-site as well as off-site tracking devices, thanks to the rapid evolution and development of technology. The Web Portal Services are the resource hub of all these critical information which has made geospatial technologies a vital asset in all stages of disaster management, including prevention, mitigation, preparedness, rescue, relief, and recovery. With the assistance of big data and artificial intelligence-powered machine learning tools, numerous other technologies have engaged with a diverse group of decision-makers by creating interfaces and applications that can be accessed on portable smart devices worldwide. The progress made in Remote Sensing (RS) has made a noteworthy contribution to the enhancement of the spatial and temporal resolutions of optical and radar sensors. Terrestrial mobile units have enhanced emergency response capabilities by implementing real-time video conferencing,

ensuring prompt and effective response. The Spatial Data Infrastructure (SDI) offers a comprehensive system for efficient data acquisition, retention, geospatial analysis, and dissemination to facilitate disaster management. Artificial intelligence and big data technology have recently been extensively utilized in the quantitative comprehension of natural phenomena. The integration of point clouds, 3D Geographic Information System, Building Information Modeling System (BIMS), and sensor information has proven effective in various emergency response applications, utilizing 3D capture of disaster scenarios. More so all information obtained is integrated into super computing platform and shared in live mode during all facets of disaster management. Despite so many advancements in data capturing, this chapter explains various challenges that distinguish our world of intelligence, timely decision-making, and smart communications in disaster management paradigm.

Disaster management · GIS · Remote sensing · GPS · Geomatics

Introduction

Disasters have been happening since the beginning of our existence in this planet. Government agencies, decision-makers, and disaster professionals are familiar with geoinformation technologies for understanding disaster risks and losses. Natural causes of disasters such as torrential rainfall, storm surges, violent volcanic activities, flood inundations, and earthquakes have claimed several lives, destroying food, shelter, and place (Bhanumurthy & Sharma, 2019; Bhatt & Karnatak, 2019). The minimizing of fatalities and property damages could be accomplished by the provision of improved data on the demographics of at-risk communities and susceptible infrastructure, the ecological variables, and the characteristics and dynamics of the various types of hazards. The availability of information is on the rise, accompanied by technological advancements such as meteorological and earth observation satellites, communication satellites, and satellite-based positioning technologies. These technologies are complemented by hazard-vulnerability-risk modeling and GIS.

With the advent of Remote Sensing (RS) techniques significant leap towards acquiring of critical information about the physical characteristics of an area using electromagnetic radiations reflected back from the surface without having to touch them. The incorporation of these technologies into a disaster risk reduction strategy, alongside their integration with national and community risk management frameworks, presents a significant opportunity to mitigate the impact on human life and physical assets. The utilization of this method enables the surveillance of the dispersion of an occurrence of air pollution that arises from an inadvertent discharge of radioactive matter or any other hazardous element into the atmosphere. Additionally, it facilitates the identification of potential groundwater contamination within a particular area. Specialized programming tools are often developed to analyze the

interdependent impact of satellite imagery, drone imagery, and Multiparametric Geophysical Observatory (MPGO) sensor data.

In the wake of the hour India has also introduced the National Geospatial Policy 2022 (NGP) (The National Geospatial Program Division, 2022), and the Draft Space Bill to encourage the development of geospatial technology and to take advantage of economic growth in many economic areas. All stakeholders, including many of the Government of India mission-mode projects like the National Infrastructure Pipeline, National Hydrology Project, PM Gati Shakti – National masterplan for multi-modal connectivity, Namami Gange, Sagarmala, and the Digital India Land Records Modernization Programme (DILRMP), benefit from the use of geospatial data for planning and monitoring. The NGP's goal is to advance geospatial science and technology, public policy, practical solutions, entrepreneurship, and international collaboration for sustained socioeconomic growth at all levels of governance. The Geospatial Data Act of 2018 (National Geospatial Deliverable Standard, 2018) of the USA requires agencies to collect, maintain, disseminate, and preserve geospatial data such that resulting data, information, or products can be shared comprehensively across all projects. Geospatial technologies are used for mapping and monitoring potential hazards, assessing risks and vulnerabilities, conducting post-disaster survey, auditing the prevention measures taken, planning and coordinating multi agency and multi stake holder's emergency responses. The use of GPS (for coordinates), coupled with GIS and Remote Sensing (RS) data, has been employed to assist in compiling quick damage estimates (Reinsel et al. 2018). Web-GIS-aided disaster preparedness, incident response, and recovery and reconstruction measures have been found very effective (Coppola, 2015). Remote Sensing involves the use of sensors that are mounted on aircrafts or satellites to capture images of the Earth's surface. These images are then processed to extract useful information about the geo-environment, such as vegetation cover, land use and land cover (LULC), meteorological information, population density, etc. Remote sensing is used to map the extent and severity of a disaster, such as floods, fires, or landslides. Remote sensing can be used to detect changes in water levels or to identify damaged infrastructure. Remote sensing can also be used to monitor the progress of a disaster, such as the spread of wildfire, or to track the movement of people or goods during an evacuation. On the other hand, GIS allows users to capture, store, manipulate, analyze, and present spatial data. GIS collects data from various sources, including remote sensing data, and integrates it into a common spatial reference system. GIS provides a platform for managing and analyzing spatial data, and enables users to make informed decisions based on the analysis of spatial data (Tomaszewski 2015). GIS can be used to identify vulnerable areas and population groups, and to develop evacuation plans. During disaster, the Incident Commander could track the movement of resources, such as emergency vehicles or supplies, and to coordinate rescue and relief efforts.

A framework for assisting at-risk individuals and/or communities to avoid, minimize, or recover from the impact of the catastrophe event is provided by disaster management issues, which encompass the pre-during-post activities related to disaster occurrence. Organizations in charge of disaster management are tasked with

lowering community vulnerability and developing capacities for handling and fast recovering from calamities. The last several years have seen an increase in the complexity of catastrophe management. Large-scale disasters appear to be happening more frequently, and new hazards are present. Multiple departments must work together and be supported by disaster managers during preparation, response, and recovery.

Geospatial Tools

In recent years, geospatial technology has grown in significance and is now used in a number of industries, including forestry, disaster management, forestry, logistics, defense, and resource management. Global atmospheric data analysis using satellite sensors is essential for forecasting natural disasters like hurricanes and tsunamis (Dilo & Zlatanova, 2011; Erden & Coskun, 2010). Efforts are being made to gather, store, and integrate environmental monitoring data with health services. There is also a growing trend to correlate everyday environmental conditions with outcomes in public health. Healthcare professionals and policymakers can improve public health by using satellite data to develop better prevention and mitigation strategies. The relationship between ground- and space-based air quality observations and respiratory health, as well as the use of satellite data to enhance health services, has been the subject of numerous research (Ghawana & Zlatanova, 2018; Phillips et al., 2012).

Agriculture, healthcare, disaster management, forestry, logistics, defense, and resource management are just a few of the industries that are currently using geospatial technology as it has grown in significance. In order to forecast natural disasters like hurricanes and tsunamis, satellite sensors are essential for monitoring global atmospheric data (Dilo & Zlatanova, 2011; Erden & Coskun, 2010). Additionally, there is a growing movement to connect current environmental conditions with results in public health, and initiatives are being made to gather, store, and incorporate environmental monitoring data with health services. Healthcare professionals and policymakers can create better prevention and mitigation methods to enhance public health by utilizing satellite data. There have been several research on how to link air quality observations from the ground and space to respiratory health and how satellite data might be used to enhance health services (Ghawana & Zlatanova, 2018; Phillips et al., 2012).

The GNSS (Global Navigation Satellite System), which includes GPS, GLONASS, and European Galileo; Geographic Information Systems/Science (GIS); and Remote Sensing (RS) – three geomatics technologies – play a crucial role in hazard mitigation. GIS manages large volumes of spatial data in both vector and raster formats, allowing for spatial queries, attribute queries, overlaying analysis, 2D and 3D spatial analyses, and data visualization in various formats; RS acquires both geometric and physical information of objects, making it a valuable tool for various studies, including land use detection and agriculture crop classification. High-resolution satellite photos can act as a foundation upon which additional data

can be placed or used in conjunction. While GIS handles and analyses data, GPS and RS primarily acquire data, and they are frequently integrated in many applications.

During all stages of a natural disaster, GIS is equipped with analytical skills that support decision-making and data integration. Risk assessment, hazard mapping, warning, and forecasting for occurrences like floods, forest fires, landslides, earthquakes, and tropical cyclones are all possible with it. The platform for many disaster management systems is GIS. GIS can also carry out the following tasks: Store, process, and combine multiple data types connected to catastrophic events in an effective and efficient manner using a variety of formats, such as through custom integrations with other systems (such electronic display boards).

- (a) By managing data in real time, GIS allows emergency managers to integrate data on the fly, visualize, and analyze events as they unfold. Wireless technology also enables dynamic data exchange from the field to the geo-database in the office.
- (b) GIS can analyze risk and predict the most likely outcome in high-risk areas based on historical data. The results can be presented in detailed maps and analytical reports. Analyzing hazard and risk information with demographics can help identify those who will be most affected and prioritize their needs.
- (c) GIS can automatically send alerts to people in a defined area within a specified time period, such as for landslides, live bomb threats, etc. It can also provide specific messages to people with special needs, such as those with respiratory issues or the elderly, as identified from hospital data or national health portals.
- (d) Spatial analysis in GIS can help identify the factors and elements related to the hazard. It can model disaster behavior and estimate damage losses through multidimensional analysis.
- (e) GIS can produce a buffer zone in the disaster area and estimate the surrounding population affected. It can also identify the shortest route between shelter centers and victims while avoiding dangerous areas.
- (f) GIS can mobilize first responders, intensive care units, and hospitals as needed, and ensure engagement through two-way communication.

Application of Geospatial Technologies

In order to help decision-makers better understand the physical environment and its potential dangers, geospatial technology is becoming more and more crucial in providing crucial information, such as the location and extent of damage, the location of people in need of assistance, and the distribution of resources like food, water, and medical supplies. Applications for geospatial technology include tracking the expansion of refugee camps and mapping volcanic eruptions using high-resolution satellite data, predicting the potential health effects of dust storms and mapping flood-prone areas using satellite images, spotting structural deformation during construction and tracking crustal deformation using GNSS and InSAR (Interferometric Synthetic Aperture Radar), and using a variety of other techniques.

By making it easier to plan, design, and manage urban infrastructure and services including transportation, electricity, water supply, waste management, and public safety, geospatial technology is also playing a crucial part in the creation of smart cities. By providing real-time data on traffic flow, air quality, energy usage, and emergency response, it can help maximize the utilization of resources and enhance inhabitants' quality of life.

Geospatial technology is additionally utilized in agriculture to improve crop management by analysis of soil characteristics, vegetation development, and weather patterns. Additionally, it can help in estimating crop yields and locating probable insect infestation or crop disease hotspots.

In summary, geospatial technology has become an essential tool in various domains, including disaster management, healthcare, agriculture, smart city development, and resource management, by providing critical information for decision-making and enhancing our understanding of the physical environment.

Some of the most common applications of geospatial technology in disaster management are:

- (a) Hazard Mapping: To map and monitor natural hazards such as earthquakes, floods, and wildfires. This helps in identifying the areas that are most vulnerable to disasters and informing disaster management strategies.
- (b) Risk Assessment: To assess the risk of disasters in a particular area. This involves analyzing data related to land use, terrain, and other environmental factors to identify areas that are more prone to disasters.
- (c) Emergency Response Planning: To develop emergency response plans. This includes identifying evacuation routes and shelter locations and planning the deployment of emergency personnel and resources.
- (d) Damage Assessment: To assess the extent of damage caused by a disaster. This involves analyzing satellite imagery and drone footage to identify areas that have been affected by the disaster.
- (e) Search and Rescue: To locate people who are in need of assistance. This includes using drones to search for missing persons and using location data from mobile phones to locate people in need of rescue.
- (f) Resource Management: To manage resources such as food, water, and medical supplies during a disaster. This involves identifying the locations of these resources and coordinating their distribution to those in need.
- (g) Post-Disaster Recovery: To aid in the recovery process after a disaster. This includes identifying damaged infrastructure and buildings and planning for their repair and reconstruction.
- (h) Emergency Communication: To facilitate communication during a disaster. This includes using mapping software to share information about the location of shelters, evacuation routes, and emergency personnel.
- (i) Public Awareness: To raise public awareness about disaster risks and preparedness and timely communications to citizens so that citizens are able to think spatially and understand how to use maps and other spatial navigation devices

- during a disaster situation. This includes creating maps and other visualizations to communicate information about disaster risks and response strategies.
- (j) Healthcare: The healthcare industry has heavily relied on geospatial tools and dashboards during the COVID-19 pandemic to monitor contact tracing, containment zones, disinfection efforts, migrant support, and vaccine distribution.
 - (k) Societal Problems: Geospatial technologies are increasingly utilized to address complex societal problems such as education, livelihood, financial inclusion, and natural resource management.
 - (l) Real estate: Remote sensing technologies and drone mapping are now commonly used in the real estate industry for visualization and analysis of properties.
 - (m) Insurance: Geospatial technology plays a vital role in risk management for specific areas such as parametric-based agro-farming through historical georeferenced data analysis in the insurance industry.

All disasters have a geographic and temporal impact that determines the extent and duration of their effects on the Earth's surface. Location plays a crucial role in disaster management response, and preparedness is key to facilitating an effective response. To determine the location, we need to utilize various geospatial data resources such as imagery, maps, datasets, tools, and procedures that link every event, feature, or entity to a location on the Earth's surface, and leverage this information for disaster management purposes. With the advancements in technology, huge volumes of data are generated from various sensors including satellite sensors, smartphones, social media, Internet of Things (IoT), Global Navigation Satellite System (GNSS), radio frequency identification (RFID), among others.

In December 2006, the United Nations General Assembly passed resolution 61/110 ([UNGGM, 2017](#)) to create the United Nations Platform for Space-based Information for Disaster Management and Emergency Response (UN-SPIDER) with a mission statement to “Ensure that all countries and international and regional organizations have access to and develop the capacity to use all types of space-based information to support the full disaster management cycle.” This platform works on the usage of space-based technologies for emergency response to connect the disaster management and space-based communities in addition to being a facilitator of capacity-building and multidisciplinary institutional strengthening ([UNDRR, 2019](#)).

Conclusion

Critical event management and public warning solutions which supports government authorities and emergency responders through every stage of a crisis is the hallmark of Geospatial technologies that provide a platform for visualizing disaster situations and explore various facets of analyzing and preparing for emergency measures. It also gives near to real situation to the incident response commander. The availability of geospatial data and information has been greatly expanded by the

use of Geoweb services and online open data repositories, offering a wide range of data formats, scales, and resolutions from global to local levels for scientific studies in the geospatial domain.

Abstract

The devastating effect and mitigation challenges due to landslide-related hazard have recently been observed to intensify manifold. Pertinently, it is time to accept that research works dedicated to landslide hazard zonation could not restrain itself

Dr. P. K. Champati ray died before publication of this work was completed.

from subjectivity as LHZ is operator, algorithm, and data-dependent. However, real-time mitigation mostly strives for available tailor-made solutions to alleviate effects of hazard. Thus, there is an ever-increasing demand to employ process-based modeling of mass movements involving snow avalanche, debris flows, and landslides. Numerical simulation and modeling using satellite data, ad rem, is still in budding stage in India but capable of objectively predicting runout in three dimensions and provide critical geophysical parameters, viz., velocity, momentum, height, and pressure at most vulnerable locations with a post-facto and predictive approach.

This research work not only takes cues from advanced satellite-derived products but also engages emerging aerospace technology involving UAV, TLS, etc. as the mainstay that caters to ultra-high-resolution terrain attributes essential for landslide modeling in an integrated manner, designing remedial measures, to evacuate people and also help to simulate and understand the actual cause, process, and mechanism of landslides. In comparison to the space-borne inputs, the airborne or terrestrial platforms are better equipped with operational flexibility, rapid deployment, flight repeatability, low operational costs, and fewer weather-related flying. This work, thus, holistically aims to model selected landslides from India and abroad to showcase the use of EO and geospatial technology in disaster mitigation.

Keywords

Debris flow · Numerical simulation · Disaster mitigation · Geospatial technology

Introduction

Landslides constitute one of the main prevailing geological hazards in the mountainous areas across the globe and are controlled by different types of causative and triggering factors like slope, geomorphology, drainage, vegetation, rock types and disconformities, torrential rainfalls, cloudbursts, glacial lake outburst (GLOF), seismicity, reservoir drawdown and off late, prodigal anthropogenic activities, etc. (Chatteraj et al., 2019; Cruden & Varnes, 1996; Guzzetti et al., 2002; Khanna et al., 2021; Pourghasemi et al., 2012). Pertinently, changes in global climatic conditions in recent years leading to extreme weather events have also contributed in enhanced frequency of landslides (Zou et al., 2021).

In the Himalaya and other mountainous regions in India, specially the Deccan Sahyadri hills, landslide emerges as a hindrance to growth of human life, property, and living of this mountainous area which is based principally on religious trips or Yatra, tourism, and cultivation (Anbalagan, 1992; Anbalagan et al., 2015; Chatteraj et al., 2019; Champati ray & Chatteraj, 2014; Chatteraj & Ray, 2015; Gupta et al., 1993; Kumar et al., 2012; Onagh et al., 2012; Sarkar et al., 1995, 2006; Sundriyal et al., 2007). Froude and Petley (2018) reported that the Indian Himalayas are one of the major global landslide hotspots and account for about 16% of the landslides triggered by rainfall. An estimate by the NIDM (National Institute of Disaster

Management) in the year 2011 and EM-DAT (Emergency Events Database) report (2010–2020) highlighted respectively annual financial losses owing to landslides are of the order of INR 150–200 cores every year in India and affecting more than 1.7 lakhs people. Nonetheless, recent landslide events in Sikkim (2011), the Kedarnath disaster in Uttarakhand (2013), and the Chamoli incident (2021) signify the graveness of the concern (Chattoraj et al., 2019; Martha et al., 2021; Pandey et al., 2021; Shrestha et al., 2021; Shugar et al., 2021).

Characteristically, the Himalayan landslides are typically of smaller dimension and with shallow depth of slip surface, on an average. But unfortunately, they are complimented by frequency of occurrence, in some cases which spread across a decade. Most of these landslides are not only responsible for putting life and property at stake but exhibit changes in landform due to mass wasting, LLOFs (Landslide Lake Outburst Flood), GLOFs (Glacial Lake Outburst flood), river aggradation, etc. (Champati ray, 2013; Champati ray et al., 2015). All such features, albeit, have been mapped, monitored, and meddled for the last two decades, but these studies gained a boost after the invention and application of space-based products. Earth observation from remote sensing satellites can provide authentic and timely information on the extent of landslides in a cost-effective and timely manner.

Analysis of landslides taking cues from EO or ancillary data has expanded beyond simple hazard zonation mapping, albeit still relevant. Rainfall-triggered landslide models, on the other hand, have also reached academic maturity to provide aid in development of successful strategy for landslide hazard mitigation (Brand, 1995; Chattoraj, Ketholia, Champati ray, & Pardeshi, 2015b; Deganutti et al., 2000; Scott, 2000). However, it is time to integrate such abundant piecemeal studies in the holistic analysis of landslide which depends on inputs from advanced research components. Thus, the need arises for understanding the physical modeling using mathematical simulation techniques in compliment to LHZ (Landslide Hazard Zonation) and rainfall threshold models. Unfortunately, there are fewer studies available for this novel approach in this part of the Himalaya.

This work, hence, aims to fill in knowledge gap in the field of numerical simulation and modeling of landslide-related hazards, with a special focus on geospatial technology and to demonstrate applications of satellite-derived products in selected case studies from the Uttarakhand Himalaya and Bangladesh. This work gives an overview of the case studies related to post facto analysis of landslides including reactivated cases and predictive modeling for future flows and, thus, portrays an inclusive review of earlier works with an essence of recent value addition. Derivation of the important physical flow parameters taking cues from earth observation techniques to understand the root cause of the devastation is the mainstay of the work, which is directly relevant to effective mitigation measures.

Study Area

It will be worth mentioning here that most of the bigger landslides have a debris flow component which is capable of causing en-route damage (Chattoraj, 2016; Chattoraj et al., 2014; Chattoraj, Ketholia, Champati ray, & Kannaujiya, 2015a;

Fig. 1 Schematic locations of landslides (star symbol with yellow border) and major localities in the vicinity (triangle symbol with white border) from parts of the Uttarakhand Himalaya and South Eastern Bangladesh plotted on Google Earth imagery

Champati ray et al., 2013). Accordingly, the selected case study areas include either active, old, or stabilized and potential areas representative of different altitude, geology, and geomorphology in Indian subcontinent, viz., (1) Kaliasaur landslide ($30^{\circ}14'30''N$, $78^{\circ}53'53''E$) on the bank of Alaknanda river, near Srinagar town in Pauri Garhwal district of Garhwal-Himalayan Region, (2) Baliyanala landslide in Nainital ($29^{\circ}22'27''N$, $79^{\circ}28'4''E$) in Nainital district of Kumaon region, (3) Malaria ($30^{\circ}40'12''N$, $79^{\circ}54'24''E$) in Dhauliganga sub-basin, (4) Langsi Landslide ($30^{\circ}29'3''N$, $79^{\circ}28'48.5''E$), close to Joshimath, and (5) Betchora Headman para ($22^{\circ}7'20''N$, $92^{\circ}15'39.5''E$) and Lama Bus Station area landslide ($22^{\circ}11'00''N$, $92^{\circ}13'13.50''E$), close to Chattogram in Bangladesh (Fig. 1).

Methodology and Input Data

Source Area Characterization

The initiation zones of targeted debris flows were identified based on field observations and visual and/or digital analysis of satellite data, as discussed:

Kaliasaur

Source area of Kaliasaur landslide (aka. Seerobagad landslide) is located at an elevation of 770 m and is distributed for about 22–23 m below road till it reaches Alaknanda river bend. The width of the slide ranges from 40 to about 100 m. The slope is steep and often reaches up to 60–70° towards south west. The slide is covering a distance of 100–150 m wide along the road (NH-58) and total height is about 1 km from the bottom of the river to the top of the slide. The rock type of the study area is Uttyasu Quartzite of Rudraprayag Formation consisting of white, pink, purple, medium- to coarse-grained, profusely ripple marked quartzite, and subordinate purple/greenish gray slates with basic metavolcanics (Kumar et al., 2012). The estimated run out length of the slide is close to 400 m.

Baliyanala Landslide

The source of Baliyanala landslide is located at 1850 m above MSL with the Krol Limestone as the main lithology with subordinate quartzite. The slide is divided into

two broad channels, each having maximum width of 150 m and length of 390 m. The slide is strategically important as density built up area at the source area. The east facing slope is on an average 45° with maximum value of 70° . The source area is characterized by many shear zones.

Malari Avalanche Chute

The potential avalanche site was located in the south east of the Malari village in the higher Himalaya with an altitude of more than 5000 m MSL and slope ranging between 10° and 80° facing north west. The predicted length of the total runout path of the chute is about 5300 m. Geologically the area is close to Himadri/Malari fault which brings Central Crystalline rock types in contact with Tethyan sequence (Sethia et al., 2018; Thakur & Rawat, 1992; Valdiya et al., 1999).

Langsi Landslide
