A large number of landslide activities are reported from different parts of the basin mainly along the National Highway-58 highway which runs for 128 km along the Alaknanda River. Close to Joshimath, the Langsi landslide has its crown lying at 150 m above the road and its toe 100 m below the road. The area is close to the Munsiari thrust passing along the Patal Ganga Valley (Kuthari, 2007). The slide is at times vertical with an average west dipping slope of 47° . The total runout path is about 1250 m.

Betchora Headman Para and Lama Bus Station Area, Bangladesh

Geographically Bangladesh is a floodplain area, and most of the hilly terrain is situated in the Chittagong region and a small part surrounded in the Sylhet region, and thus natural disasters always affect this area (Ahmed et al., 2014; Ahmed, 2015; Mia et al., 2015). Sudden and excessive rainfall triggered flash flood and landslide have become significant disasters in the South-East and North-East hilly regions of Bangladesh and occurring frequently almost every year (Ahmed, 2015; Moniruzzaman & Chattoraj, 2021; Sarker & Rashid, 2013). These landslides are located (at 60–80 m above MSL) close to Bandarban in Chattogram area which mainly consists of small hillocks of maximum height of 100 m on the banks of Sangu river. The riverine hillocks have relatively smaller runout compared to other study areas. Geologically they are in the proximity of Chittagong-Tripura Fold Belt and comprise of the Miocene to Pleistocene claystone and sandstones of the Surma and Tipum Group (Fig. 2).

Model Input Data

Satellite Data Including Digital Elevation Model

Topographic inputs like elevation, slope, and aspect are few of the fundamental inputs required for simulation using RAMMS (Rapid Mass Movement Software), in compliment with release area, mass, and density of the rocks characterizing the source area. Pertinently, a good resolution, i.e., less than 10 m spatial resolution, is, hence, the first thing to start with a model required for numerical modeling. In this study, ALOS (Advanced Land Observing Satellite) PALSAR 12.5 m DEM (Digital Elevation

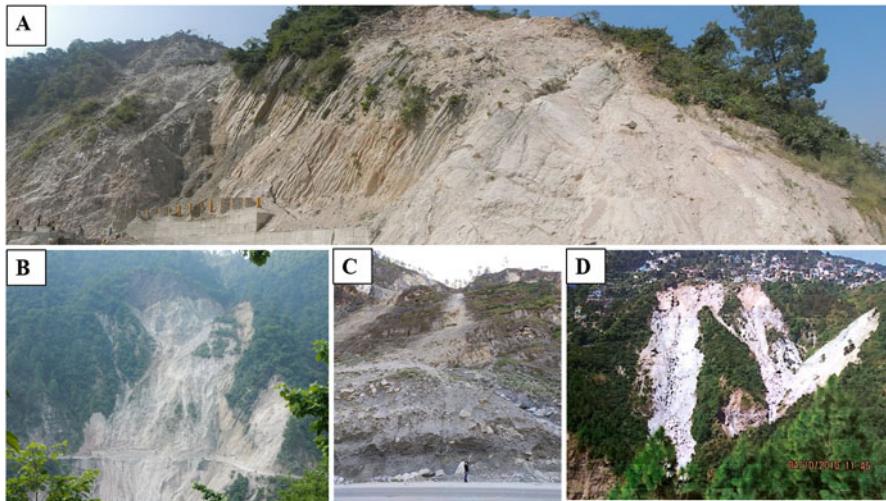

Fig. 2 Field photographs of few of the modeled landslides: (a, b) panoramic view of the Kaliasur landslide showing exposures of quartzites (length of retaining wall and road affected by landslide are ~60 m and 100 m, respectively); (c) Langsi landslide above road (height of the person is about 1.5 m); (d) panoramic view of the Balyanala landslide exposing part of the Krol Limestone (length of the right branch of the slide is ~350 m)

Model), converted to ESRI (Environmental Systems Research Institute) ASCII (American Standard Code for Information Interchange) grid was used for all study areas. Cues were also taken from Cartosat DEM (10 m) to check the landslide areas in three dimensions. High-resolution geospatial mapping, off late, is trending mostly in the domain of UAVs (Unmanned Aerial Vehicle) which are either multi-rotor or fixed drone. More flexible multi-rotor UAV drone, in this case study, has been utilized at places to generate DEMs of ground sampling distance which is less than 5 cm. Use of airborne platform promotes improved work safety, rapid deployability, and flexibility of operation and encourages flight repeatability at minimal one time operational costs and less weather-related flying limitations over traditional platforms (Chatteraj et al., 2021).

However, other input parameters like friction and geo-mechanical properties are also crucial to get idea about the resisting forces arising out of solid and liquid phases present in debris. The release and movement of geophysical mass, en-route, can also be influenced by vegetation, etc. The starting conditions, in this study, have been assumed to be of block release type for simplicity (block release of Rickenmann et al., 2006, Rickenmann, 2005, Rickenmann et al., 2006, Rickenmann, 2016). Though simulations ideally should be capable of mimicking both channelized and un-channelized debris flows, it is observed that un-channelized debris flow condition for hillslope debris flows could be best simulated by this. Albeit, the models developed for the selected study areas consist of both channelized and un-channelized flow paths which were validated on Sentinel 2B and IRS (Indian Remote Sensing satellite) LISS-IV (Linear Imaging Self Scanning Sensor) multispectral images. In the present study, landslide-specific release areas were identified which have been demarcated over the DEM. Apart from providing

a release area, a calculation domain (local water divide restricting the flow) was also delineated on DEM for better visualization of the runout.

Frictional and Shear Strength Parameters and Calibration of the Model

Mathematically RAMMS simulation is based on characterization of rheological properties of the rocks and debris responsible for facilitating shear strength failure. This takes cues from the Voellmy friction law (Salm et al., 1990). Debris flow ideally comprises of an in situ or otherwise solid (rock) phase, chunks, soil, river-borne material, and associated debris, and liquid phase, mostly water/slurry phase. Hence, the frictional resistance forces consist of dry-Coulomb-type friction (coefficient, μ) from the rock phases, directly related to normal stress and a velocity-squared drag or viscous-turbulent friction (coefficient, ξ) arising out of the liquid phase. The geo-technical inputs to the model for calculation of total shear strength would be cohesion (C) and anger of inter resistance (φ) which can be derived both empirically and instrumentally. The total resistance provided by the material due to friction S (in Pa) is formulated as:

$$S = \mu\rho H g \cos\theta + (\rho g U^2)/\xi$$

where ρ is the density of the mass, g the acceleration due to gravitational force, φ the slope in ($^\circ$), H the flow height, and U the initial velocity of the flow. The initial velocity is often non zero as in case most of the debris flows with substantially large source area. Physical samples of debris collected from the depositional zone of the flow were analyzed to get their shear strength parameters in electronic direct shear testing equipment at the Indian Institute of Remote Sensing, Dehradun (Model No. AIM 104), at maximum saturation level without inducing a mechanical shear plane. Samples were analyzed at different impounding normal load to get an idea about shear failures.

As for the validation, the simulated flow should match the observed flow paths. Therefore, a set of simulations were run with different values of input parameters to get the desired results. The input parameters were validated with instrumentally derived ones, and simulation results were validated with naturally observed flow paths, and the best fitted simulation outputs were, therefore, adopted (Sosio et al., 2008). This whole approach requires to search for site-specific optimal friction values from standard tables pertaining to particular type of debris. Numerous simulations were performed with the μ ranging from 0.05 to 0.25. On the other hand, viscous turbulent flow ranges from 100 to 1500 m/s² with a fixed density, release height, etc. Amidst all the simulations, the one which was closest to the dimension and runout of the real debris flow was chosen to be best fit, which was further subject to validation by satellite images and field validation. The parameters helped to recognize the same in satellite images were, viz., the total length of runout distance, their spatial coverage, arcuate shape of the flow, lighter tone, variation in

pattern, and association of geomorphic features detectable in the debris flow zone and outside its influence. To zero-in on best fit model from many possible modeled outcomes, pixel-wise spatial matching technique was adopted in GIS (Geographic Information System) platform to detect the extent of matching of dimensions of modeled flow vis-à-vis the actual landslide as portrayed in the image with an error bar of $\pm 10\%$. It is intriguing to note that shortening of the runout path happened with an enhancement in the frictional coefficient μ (M_u) as it caused an enhanced drag upslope to the mass. Increase in ζ (X_i) value in a relatively smoother flow with proportionate increase in runout length adds to dilution of the flow.

On a general note, as for the results discussed below, caution is to be maintained as momentum is not absolute. This is due to the fact that RAMMS simply considers momentum to be a product of velocity and height of the flow and so is its unit (m^2/s). Density of the material and area under influence are also to be considered to obtain the real momentum in kg-m/s. The numeral simulation model does not, as well, consider en-route erosion and additional contribution from side channel into the main flowing mass along runout which results in lower value ranges for output parameters. Landslide validation carried out by visual estimation/ digital feature extractions of satellite data is also subject to human error and field validation.

Result and Discussion

Interpretation of Simulation

Kaliasaur

The final simulation gives the value of total release volume as $20245\ m^3$ and has a total runout length of 360 m. The simulated height gives maximum value of 1.79 m at the initiation point and above the road cut. The height remains constant (1–0.8 m) up to the road (i.e., up to 120 m). Thereafter, the height decreases from 0.8 to 0.6 m and at the base, maximum height is 0.1–0.2 m. The modeled result reveals that maximum velocity (14.26 m/s) is found at the initiation zone and above the road. It is evident that velocity of 8–14 m/s continues up to 18 m and then suddenly falls to 6–4 m/s between 200 and 300 m. At the road cut maximum velocity is 7–8 m/s. At the base maximum velocity is 2–3 m/s. According to the model result, simulated momentum gives maximum value of $16.41\ m^2/s$ at the initiation zone and pressure is about 528.61 kPa at the initiation zone and above the road. The main focus of the study was to model the debris flow runout using numerical simulation technique. Such information is very essential for designing mitigation measures and also provides insight into the event. It is evident from the study that the debris flow is capable of providing enough debris to block the main road as well river (Fig. 3).

Baliyanala Landslide

Modeling of Baliyanala landslide provided a unique opportunity to see the contrast of the outputs derived from the satellite and airborne (UAV) derived DEMs. The debris flow at Baliyanala at Nainital shows a bifurcation from its very source region and continues to broaden at the base. As for the outputs from ALOS PALSAR DEM,

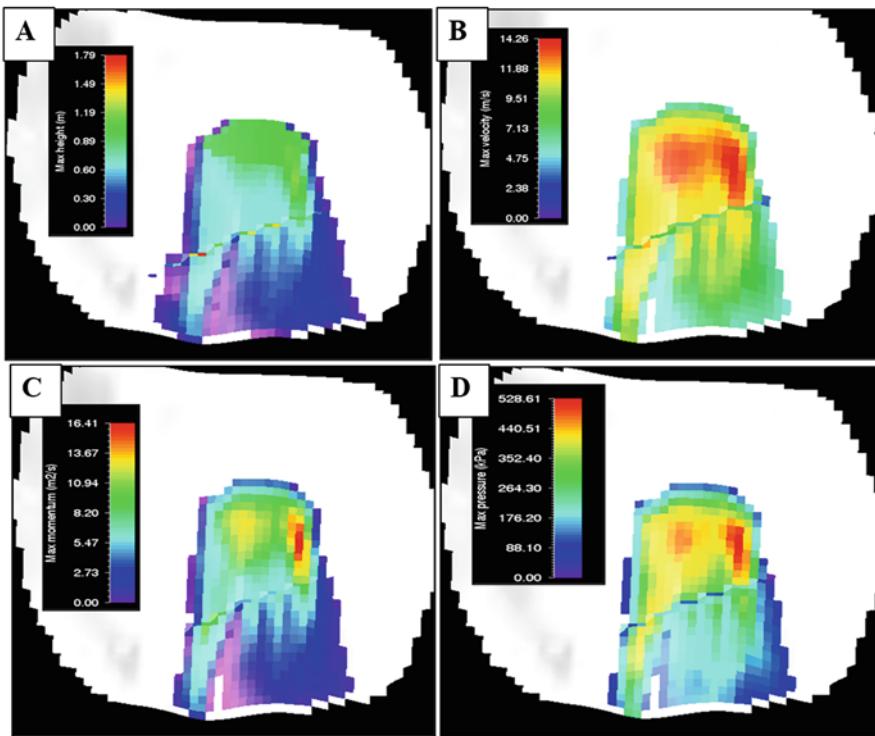

Fig. 3 Modeled outputs (maximum height, velocity, momentum, and pressure) of debris flow at Kaliasaur Landslide near Srinagar, Garhwal (**a–d**). Units of variables are in SI format

the maximum height of the flow was calculated to be 6.2 m and the maximum velocity of the flow was ~18 m/s owing to very steep slopes at several locations (Fig. 4). Maximum height anomaly is seen just below the source area in the right branch of the debris flow. The right branch flow in totality also shows maximum variation in height compared to the left branch. The right branch also shows regular hot spots in terms of velocity all throughout the runout length. However, in both cases maximum height is recorded close to source area. The results from UAV-based DEM are definitely more refined as it matches well with the ground/field measurements also. The maximum modeled height remains to be 4.7 m, and the velocity reaches 22 m/s at places, which is slightly on the higher side (Fig. 4). Variation of velocity and height along the runout path displays an almost similar trend. This result postulates that satellite and airborne platform-based DEMs used in an integrated way is, at times, necessary to make the simulated models more realistic and robust, which becomes more meaningful for mitigation point of view.

Malari

Numerical simulation at Malari is different from all other case studies presented in this work as this considers a predictive model of a potential avalanche. The model output results showed that the avalanche flow was unbranched till it reached the base

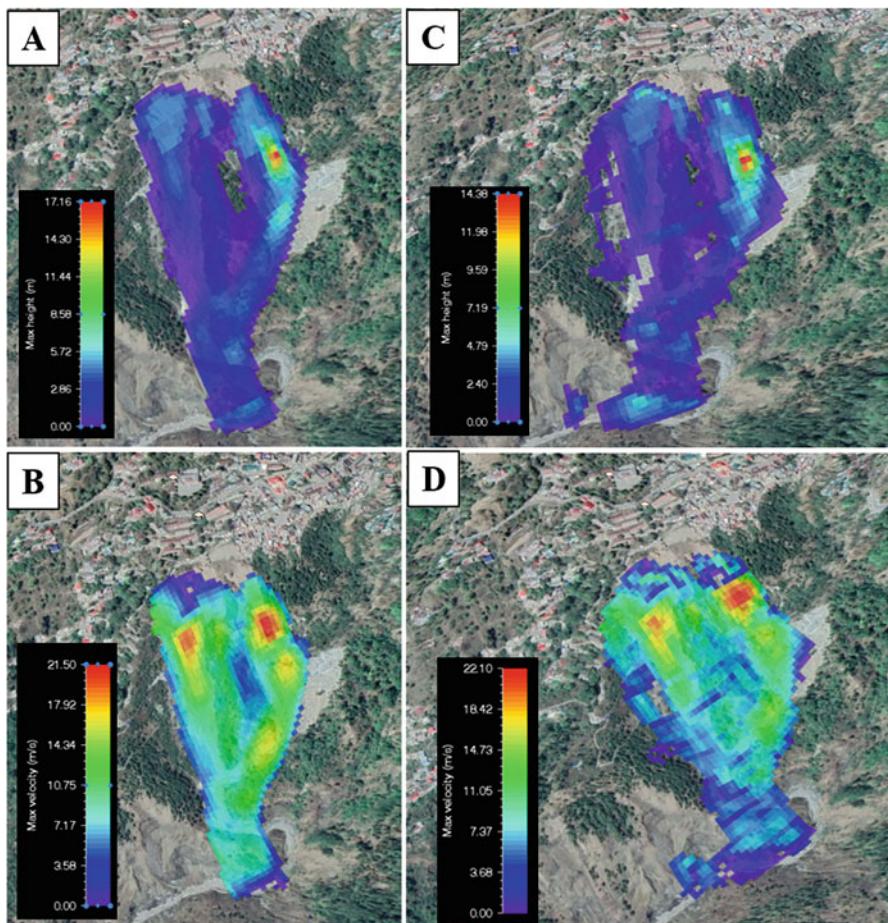

Fig. 4 Modeled outputs (maximum height and velocity) respectively from DEM derived from ALOS PALSAR (**a, b**) and UAV-based (**c, d**) of the Baliyanala Landslide in Nainital, projected on images available in Google Earth platform. Units of variables are in SI format

near a bridge in Malari village. The maximum height of the flow was ~17 m, and the maximum velocity of the flow was ~52 m/s (Fig. 5). The flow pressure was as high as up to 933 kPa. The result of the simulation indicated that the avalanche can reach up to the Malari village mar raise a concern. This work demonstrated that a potential avalanche zone mapping with a combination of numerical simulation model can be proved to be promising tools for risk prediction and evaluation in the inaccessible but strategically important Himalayan villages like Malari.

Langsi Landslide

Langsi landslide has also recurred few times in past one decade or so (Sarkar et al., 1995, 2006; Chatteraj et al., 2019). The present work represents a predictive numerical simulation of the area in case of reactivation of the slide. The outputs

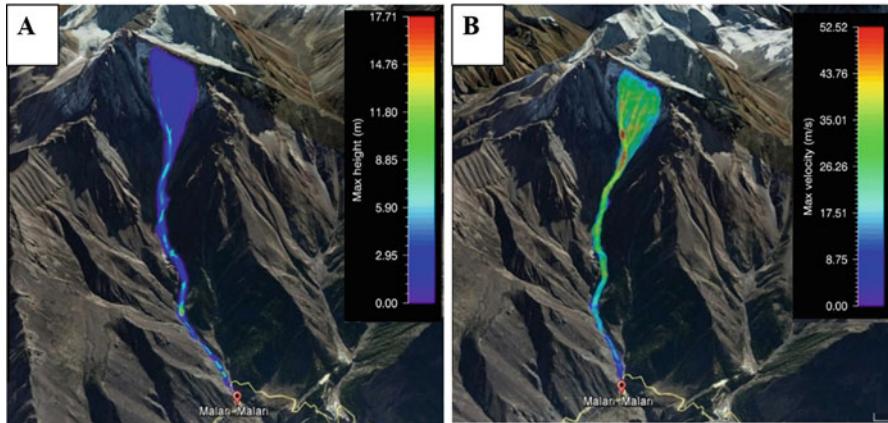

Fig. 5 (a) Modeled maximum height and (b) velocity of an avalanche location near Malari Village by predictive simulation, projected on images available in Google Earth platform

with the best-fitted simulation observed the maximum velocity of 25.75 m/s and the maximum height attained by the sliding material was 14.61 m (Fig. 6). From the following outputs, it can be inferred that if this landslide takes place again then about 14.61 m of the debris will be deposited at the bottom of the flow. Along the road, the maximum height will vary in the range of 0.5–3.1 m. So, if the flow occurs then 1 m or more of the debris will be deposited at the road, whereas the maximum velocity will vary in a range from 4.29 to 13.02 m/s depending on different locations in the road.

Lama Bus Station Area and Betchora Headman Para Landslide, Bangladesh

Betchora Headman Para site is relatively flatter with a number of settlements at the base of the small hill. The RAMMS simulation results show that the maximum flow height raised up to 2.05 m and maximum velocity of the debris found 6.02 m/s. The release volume estimated 3966.3 m^3 . Modeled maximum flow height and velocity at Lama Bus Station area are respectively 2.52 m, 9.1 m/s (Fig. 7). The estimated release volume found 23808.7 m^3 . Results are projected on the Google Map for the visualization purpose and shown in Fig. 7 where it has been clearly seen that all of the houses have been damaged by the debris flow. Results clearly indicate how devastating both the landslides can be considering the heavy built-up area at the zone of deposition.

Instrumental Validation of Shear Strength Parameters

As mentioned above, cohesion (c) and frictional coefficient for dry and liquid phases (μ and ξ , respectively) for soil/debris have been used as critical inputs to numerical simulation-derived models in this study. Cohesion is not directly related to stress

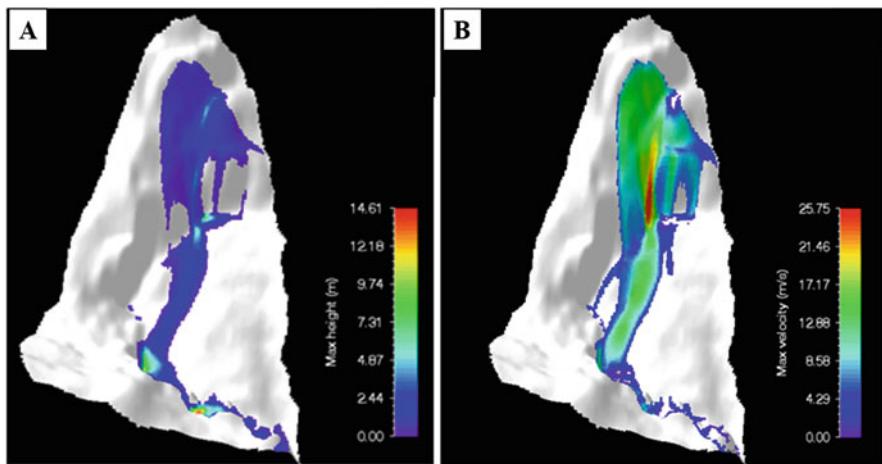

Fig. 6 Modeled outputs (maximum height and velocity) of debris flow at Langsi Landslide near Joshimath (**a, b**). Units of variables are in SI format

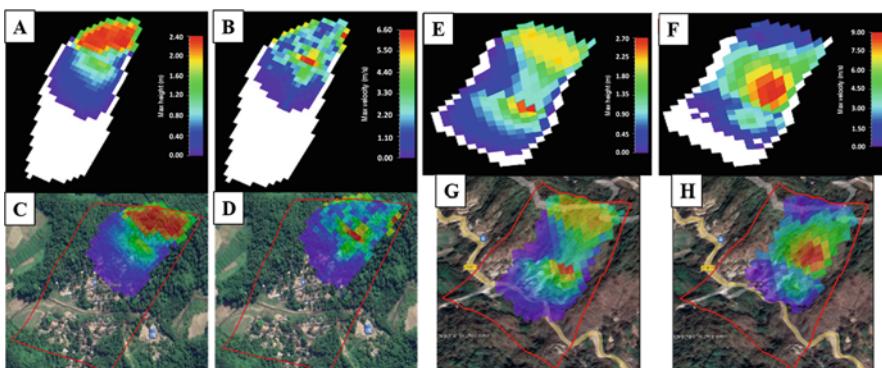

Fig. 7 Modeled outputs (maximum height and velocity) of debris flows at Betchora Headman para (**a–d**) and Lama Bus Station area (**e–h**) Landslide, Bangladesh, with their projections on imagery available in Google Earth platform, respectively. Units of variables are in SI format

system. However, if the angle of sliding is considered to be equal to angle of repose, then as per the rule of friction static frictional coefficient (μ) is intricately related to the slope of the topography. Fortunately, μ and c , both are quantifiable in the laboratory within a defined error range. It will be reiterating to mention here that for the best fit simulation, the instrument derived and modeled inputs of shear strength parameters should be similar. C and Φ were derived by analysis of samples in direct shear instrument which follows the Mohr-Coulomb failure behavior, and thereby the friction static frictional coefficient (μ) which helps to validate the model as per Table 1:

Table 1 Shear strength parameters of debris flows and avalanches: input to model vs. instrument-derived outputs

Flow characteristics		Shear strength parameters		
Flow location		Inputs provided to model	Outputs derived from direct shear instrument	
	Total runout length (Km)	Simulated flow height at base (m)	Simulated velocity at base (m/s)	Cohesion (c) (kPa)
Kaliassaur landslide	0.360	2.5	8.75	15–25
Balyanala landslide	0.58	6.2	18.5	20–30
Malari ^a	4.8	17	52	24–27
Langsi landslide	0.83	14.61 m	25.75 m/s	20–30
Beichora Headman para and Lama Bus Station	0.45–0.55	2.05–2.5	6.0–9.1	10–14
				12–15
				12.8
				15
				16

^aThe friction parameter is based on terrain characteristics that are empirically derived (Bartelt et al., 2013; Christen et al., 2010)

Conclusion

Comprehensive assessment of landslide hazard requires process-based modeling using simulation methods. This work reveals two important outputs by employing satellite images and other geo-engineering parameters, viz., (1) successful post-facto (including a potential of reactivation) and predictive future simulation of selected debris flow events showcased depicting spatial variation of geophysical parameters like velocity, height, pressure, and momentum for few most vulnerable locations. Secondly, it provides stakeholders, ranging from disaster management authority to the general public, the critical insight of the events and related consequences. It has also emerged that recent UAV-based airborne mapping provided high/ultra-high resolution terrain attributes essential for better simulation to help better decision-making and crucial to all stakeholders. It provides idea about the location and nature of implantation of check dams to digest the initial trust of such flow, thus, directly helping mitigation. The work at the same time demonstrates how best a numerical simulation be validated using earth observation-based products and engineering geological instrumentation. This work opens the scope of monitoring and modeling of future glow in a predictive way for landslides of international importance.

Abstract

The conventional method of predicting earthquakes is based on historical seismic records of earthquake-prone areas that can only provide probabilistic predictions. However, the predictions are limited in terms of precision as one cannot obtain narrow temporal and spatial windows of the impending earthquake occurrence. Hence, a method that detects earthquake precursors, for example, in the form of geomagnetic anomalies, has the potential to overcome the limitation of the conventional method. Additionally, the adoption of processing tools with a graphical user interface is highly advantageous in enabling analyses to be performed more widely. In this chapter, a software package serving as a geomagnetic signal processing system for detecting pre-earthquake anomaly is presented. The software, which was built based on in-house MATLAB code, provides an efficient and intuitive tool in detecting geomagnetic pre-earthquake anomalies and estimating the directions. The anomaly detection method is based on ultralow-frequency polarization ratio analysis, whereas direction estimation is based on the polarization ellipse technique; however, both are widely used in the field of seismo-electromagnetics. As a comprehensive software package, it allows the user to input raw and unextracted geomagnetic field data, select an earthquake of interest within a determined period of observation, and select the signal processing parameters. It also automatically acquires supplemental data including space weather data and earthquake catalog from an online repository. It then processes the data, outputs the graphical results, and sends the results to the user's email if desired. More specific details including processing principles and features are elaborated in this chapter, along with the presentation of examples of usage and outputs.

Introduction

Non-seismic techniques for observing seismo-electromagnetic phenomena particularly anomalous low-frequency geomagnetic emission have been widely adopted to achieve earthquake prediction (Stănică & Stănică, 2021; Yusof et al., 2021). It has been hypothesized that the emission can be generated at the hypocenter several days up to around a month prior to a sizeable earthquake, possibly due to the following mechanisms: (i) piezomagnetic and piezoelectric effects (Yamazaki, 2016), (ii) induced electric current caused by changes of underground conductivity (Sorokin & Pokhotelov, 2010), (iii) electrokinetic effect (Fedorov et al., 2001), and (iv) microfracturing electrification (Molchanov & Hayakawa, 1998). However,

lithospheric emissions which may be generated during the earthquake preparation phase are much weaker compared to disturbances due to sources from the different atmospheric layers of the Earth like the ionosphere and magnetosphere. In order to address this limitation, emissions within the ultralow-frequency (ULF) range of 0.01–0.10 Hz have been considered as they undergo less attenuation, thus increasing their probability of reaching the Earth's surface (Prattes et al., 2011). Furthermore, the ULF range is mostly free from various contamination sources from space that affect other frequency ranges, for instance, discharge of lightning (3 Hz–3 kHz) (Siingh et al., 2008) and high-frequency ionospheric heating (0.2–6.6 kHz) (Papadopoulos, 2005). These characteristics of ULF make it a likely candidate for the purpose of studying seismic events like earthquakes.

A complete earthquake prediction system should be able to perform two processing tasks: precursor detection and direction estimation. In order to detect precursors, the issue of weak lithospheric-originating emissions being masked by the more intense natural electromagnetic field needs to be addressed. Prior studies adopted the polarization ratio analysis method that relies on the abnormal increase of the vertical component of geomagnetic field intensity in relation to the horizontal component prior to sizeable earthquakes (Hayakawa et al., 2021; Swati et al., 2020; Yusof et al., 2019a). Meanwhile, polarization ellipse method has been successfully applied in estimating the direction of seismo-atmospheric emission within either extremely low-frequency (ELF) or ULF ranges (Schekotov et al., 2015; Yusof et al., 2021). Despite the promising findings by prior studies that adopted both methods, implementing them is not without its challenges, mainly due to the complexity of the necessary signal processing.

The complexity of the processing tasks therefore makes automation of the tasks favorable and of interest, which led to the idea of developing an interactive graphical user interface (GUI) software package. The utilization of such software could expedite essential processing routines in ensuring that predictions are obtained within an actionable timeframe prior to the earthquake. Additionally, although geomagnetic field data are continuously collected at many locations all over the world, they are owned by private organizations or individuals and are usually not made available for public use. Therefore, a GUI software package would facilitate people who have access to the data to conduct the analysis, and it would encourage them to contribute back to a central database. This database is envisioned to gather prediction analysis results from various earthquakes, and this will help in determining the relationships between earthquake properties and precursor characteristics as demonstrated by a few past studies (Schekotov et al., 2020; Yusof et al., 2021).

In this chapter, the alpha release of a software package that automates some tasks of earthquake precursor analysis based on anomalies in the geomagnetic field is presented. Several aspects of this state-of-the-art software are elaborated including the theoretical background, data description, functionalities, and user interface. Finally, an example of the outputs based on an earthquake is discussed to demonstrate the software usage.

Theoretical Background

Precursor Detection

The software adopted the polarization ratio analysis for precursor detection, which is arguably the most used method for seismo-geomagnetic anomalies. The analysis involves the calculation of the polarization ratio parameter, $P(f)$, on the i th day that is given by the following:

$$P(f)_i = \frac{\langle S_Z(f) \rangle_{\Delta f, \Delta T, i}}{\langle S_H(f) \rangle_{\Delta f, \Delta T, i}} \quad (1)$$

where S denotes power spectral density (PSD) of the vertical (Z) and horizontal (H) field components, which are then averaged over a ULF range, Δf , and a period, ΔT (Stanica & Stanica, 2019). In terms of Δf , most past studies observed a narrower range within the full ULF range (i.e., 0.01–0.10 Hz), for example, 0.03–0.05 Hz, usually without any justification (Yusof et al., 2019b). Hence, the ULF range is divided into nine frequency ranges, i.e., $\Delta f = 0.01 - 0.02, 0.02 - 0.03, \dots, 0.09 - 0.10$ Hz, and $P(f)$ is computed for all ranges by the software without making any presumptions. Additionally, only 4-hour local nighttime periods (i.e., $\Delta T = 22 - 02, 23 - 03, 00 - 04, 01 - 05, 02 - 06$ LT) are processed to reduce signal noise due to human activities like power transmission and mass production that are typically higher during the day (Potirakis et al., 2019). The splitting of frequencies and periods allows the user to interpret the outputs and decide which parameter combination produces the most desirable results in detecting a precursor for a given earthquake.

Geomagnetic field components may vary over different ranges; therefore, the normalization step was recently introduced in polarization ratio analysis to ensure that each component contributes a sensible weightage when computing $P(f)$. Normalized $P(f)$ based on z-score (Ida et al., 2008) and ranges (Yusof et al., 2020) are obtained as follows:

$$P(f)_{\text{zscore},i} = \frac{(S_{Z,i} - \mu_{S_Z})/\sigma_{S_Z}}{(S_{H,i} - \mu_{S_H})/\sigma_{S_H}} \quad (2)$$

$$P(f)_{\text{range},i} = \frac{(S_{Z,i} - S_{Z,\max})(\frac{b_Z - a_Z}{S_{Z,\max} - S_{Z,\min}}) + b_Z}{(S_{H,i} - S_{H,\max})(\frac{b_H - a_H}{S_{H,\max} - S_{H,\min}}) + b_H} \quad (3)$$

where S_Z and S_H in (2) and (3) are short forms for $\langle S_Z(f) \rangle_{\Delta f, \Delta T}$ and $\langle S_H(f) \rangle_{\Delta f, \Delta T}$, respectively. In (2), μ and σ refer to the mean and standard deviation of the parameters, respectively. Meanwhile in (3), a_Z , b_Z , a_H , and b_H are the lower and upper limits of normalization ranges for the Z and H components, respectively, where the ranges are [$a_Z = 1, b_Z = 3$] and [$a_H = 1, b_H = 2$] (Yusof et al., 2021).

The way an anomaly is identified depends on the normalization type used: $P(f)_i > \mu_{P(f)} \pm \sigma_{P(f)}$ for z-score and $P(f)_i > b_Z/b_H (=1.5)$ for ranges.

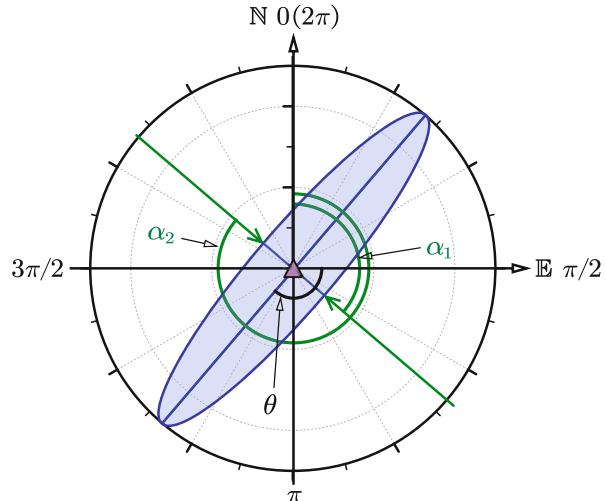

Direction Estimation

The direction from where the anomalies originate can be estimated by using the polarization ellipse method. The method relies on the concept of polarization ellipse that has a major and minor axis. It is hypothesized that the major axis will align perpendicular to the direction of incoming anomalies (Ohta et al., 2013). Figure 1 illustrates the ellipse (in light blue) and both of its axes (dark blue interior lines) where the angle the major axis makes with the eastward direction (\mathbb{E}) revolving clockwise is referred to as θ (where $\theta > 0$); its tangent can be calculated as follows:

$$\tan(2\theta) = \frac{2A_N A_E \cos(\varphi_N - \varphi_E)}{A_N^2 - A_E^2} \quad (4)$$

In (4), A_N and A_E are the instantaneous amplitudes, whereas φ_N and φ_E are the phase angles of N and E geomagnetic field components, respectively. In order to obtain the four variables, a band-pass filter within Δf range, which is determined in the precursor detection step, is applied to each component separately. The filtering modifies the original data into quasi-monochromatic signals (U_N and U_E), which are then Hilbert-transformed to get complex signals and, consequently, the four variables. Through simple geometry, one can easily obtain two possible directions of the incoming signals (green arrows), where the angles the signals make with the northward direction (\mathbb{N}) revolving clockwise are represented by α_1 and α_2 in Fig. 1, where $\alpha_1 = \theta$ and $\alpha_2 = \theta + \pi$ (Hayakawa et al., 2021).

Fig. 1 Depiction of polarization ellipse with its axes (blue oval with interior lines) and possible incoming signal directions (green arrows)

Since these angles, hereby referred to as azimuthal directions, are computed from instantaneous U_N and U_E , both α_1 and α_2 are therefore time-variant. Thus, estimating the dominant direction is necessary, which can be achieved by plotting the azimuthal distribution of α (i). Additionally, to increase the accuracy of the estimation, only α (i) that originate from high-intensity horizontal field relative to the average value (i.e., corresponds to high signal-to-noise ratio, SNR) are considered when plotting the distribution that is given by the following:

$$\sqrt{U_N^2(i) + U_E^2(i)} > k \sqrt{U_N^2 + U_E^2} \quad (5)$$

The value of coefficient k in (5), which determines the threshold of acceptable SNR, of between 3.5 and 5.0 was found to be useful in estimating the direction of ULF signals which are probably coming from earthquake epicenters (Ohta et al., 2013; Yusof et al., 2021).

The Software Package

The software package was designed and built using MATLAB® App Designer and then compiled as an executable file using MATLAB® Compiler for it to run as a standalone software package. The minimum system requirements for the software follow the ones for MATLAB® software, namely, any Intel or AMD x86–64 processor, 8 GB of disk and 4 GB of RAM on either Windows, Mac, or Linux operating systems (The MathWorks Inc., 2019).

Input and Supplemental Data

Input data The software accepts raw geomagnetic field data as the input, specifically those that are released by the Magnetic Data Acquisition System (MAGDAS). As illustrated in Fig. 2, MAGDAS is a magnetometer network with nearly 80 stations globally that is run by the International Center for Space Weather Science and Education (ICSWSE), Kyushu University, Japan (Yumoto and MAGDAS Group, 2007). Most MAGDAS magnetometers are of the ring-core fluxgate type; the magnetometers measure three magnetic orthogonal components, i.e., northward (N), eastward (E), and downward vertical (Z), as well as the total field, $F = \sqrt{N^2 + E^2 + Z^2}$ in nanotesla (nT). Along with these components, the metadata such as data and time (UTC), station location and code, elevation, and sampling frequency are also recorded in data files, which are released in the textfile format as exemplified in Fig. 3.

Supplemental data Several supplemental data are required for the software to operate properly, namely, earthquake catalog and global geomagnetic indices; both are preprocessed, packaged, and uploaded regularly to an online repository

Fig. 3 An example of daily raw geomagnetic field data file released by MAGDAS

(www.github.com). The data are automatically retrieved every time the software is initialized to ensure that the user has the most updated version of the data locally. The earthquake catalog is acquired from the European-Mediterranean Seismological Centre (EMSC) earthquake database (www.emsc-csem.org). It encompasses tens of thousands of earthquakes having magnitude $M \geq 4.5$ and hypocentral depth $h \leq 200$ km that have occurred globally since the year 2007. The catalog provides fundamental properties like occurrence time (UTC), moment magnitude, latitude, longitude, depth, and region name. The software computes the distance between a given earthquake and magnetometer station using their latitudes and longitudes, which is known as epicentral distance, r . It is essential in approximating whether precursors could be detected at a given location; Hayakawa (2015) hypothesized that precursors are detectable if $r < 40$ ($M = 4.5$). Additionally, to consolidate r and M into a single quantity that represents the impact of an earthquake at a location, the local seismicity index K_{LS} (Molchanov & Hayakawa, 2008) is calculated as follows:

$$K_{LS} = \frac{10^{0.75M}}{r + 100} \quad (6)$$

The geomagnetic field is frequently disturbed by various sources from the Sun such as geomagnetic storms and solar events, especially during solar maxima (Yusof et al., 2022). Thus, an index that describes the geomagnetic condition at a global scale needs to be observed, in contrast to the localized measurements at the magnetometer stations. The disturbance storm time (Dst) and planetary (ap) indices are therefore acquired from NASA OMNIWeb Service (www.omiweb.gsfc.nasa.gov) and observed. The Dst and ap indices are obtained by computing the average of geomagnetic field intensities at several magnetometer stations in the dip-equatorial and midlatitude/sub-auroral regions, respectively (Rostoker, 1972). As each index represents a different region, it is beneficial to observe both simultaneously to have a more generalized indicator. The periods of high solar-terrestrial disturbance are known as disturbed days, which are given by $Dst < -30$ nT or $ap > 27$ nT; otherwise, they are identified as quiet days (Namgaladze et al., 2019). If a geomagnetic anomaly is identified during a disturbed period, it will be discarded to avoid a false precursor.

Functionalities and Interface

As a versatile software, it can perform several sequential functions which include (i) geomagnetic field data extraction and preprocessing, (ii) earthquake searches, and (iii) precursor detection and direction estimation. Descriptions within this section mainly refer to Fig. 4. It is worth noting that extracted data obtained from function (i) can be saved in the MATLAB data format (*.mat) for other processing purposes

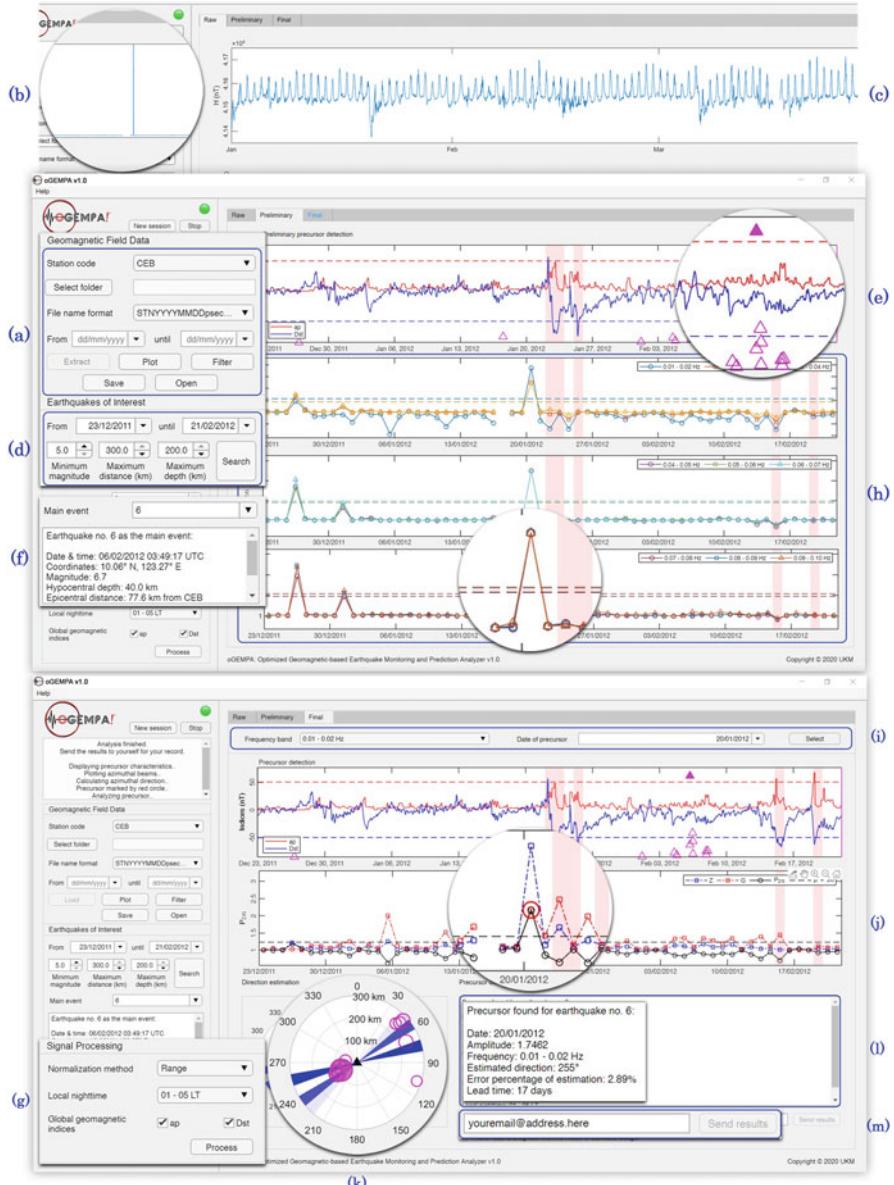

Fig. 4 The software's user interface showing its various functionalities that are marked by letters and referred in the main text

outside the software. Additionally, the software can function as a standalone earthquake seeker based on the selected station and earthquake parameters provided by function (ii) without inputting the geomagnetic field data.

Geomagnetic field data extraction and preprocessing As described in the previous section, geomagnetic field data are typically supplied by data providers in the textfile format. MAGDAS in particular releases individual files of daily data with various file extension conventions, making the extraction and merging process of the data tedious and complicated if it were to be performed manually. Additionally, despite being cleaned by the data provider prior to being released, noises and outliers sometimes persist in the raw data. As shown in Fig. 4a, the software accepts a station code selection, path to the raw data folder, file name, and extension format as well as start and end dates to perform data extraction. At present, data from all MAGDAS stations are supported, with the capability of adding more new stations as well as supporting other magnetometer networks like SuperMAG (supermag.jhuapl.edu) in future versions of the software. After setting the parameters, the software starts the extraction by iteratively opening the data files, copying the contents, and appending the contents chronologically based on associated timestamps (*Extract* button in Fig. 4a). The user can then plot the raw data for inspection or filter it to remove noises and outliers to prepare for the next processing steps (*Plot* and *Filter* button in Fig. 4a). The raw data before and after being filtered are shown in Fig. 4b and Fig. 4c, respectively. If the user has already extracted and saved the data in the MATLAB format, they can skip the previous tasks and open the data to continue with the analysis.

Earthquake searches The analysis proceeds with earthquake searches based on several parameters such as start and end dates, minimum magnitude, maximum epicentral distance, and hypocentral depth (Fig. 4d). Note that epicentral distance is measured from the magnetometer station selected beforehand. Earthquakes matching the set parameters are plotted as hollow magenta triangles with the y-axis corresponding to K_{LS} of the earthquakes as shown in Fig. 4e. Earthquakes commonly occur in a swarm with fore- and aftershocks preceding and succeeding a main shock which usually has the largest magnitude, respectively. Therefore, the software requires an earthquake to be selected as the “main event” and be the focus of the analysis, where the main shock is recommended but not compulsory. Upon selecting the main event, the triangle representing the earthquake will change from a hollow to a filled one (Fig. 4e), while the details of the earthquake will be displayed in Fig. 4f.

Precursor detection and direction estimation This part presents the main functionality of the software that starts with signal processing parameter setting which includes normalization method, local nighttime, and global geomagnetic indices as can be observed in Fig. 4g. The software automatically processes the signals in nine ULF ranges, which are then plotted to be examined by the user (Fig. 4h). The plots also indicate the $\mu + 2\sigma$ threshold for each frequency range to aid the user in identifying the anomalies that could be considered as precursors. Then, the frequency range exhibiting the precursor and the date of appearance is specified as displayed in Fig. 4i, and this prompts the software to compute the estimated azimuthal direction. As illustrated by the azimuthal plot in Fig. 4k, the blue bars

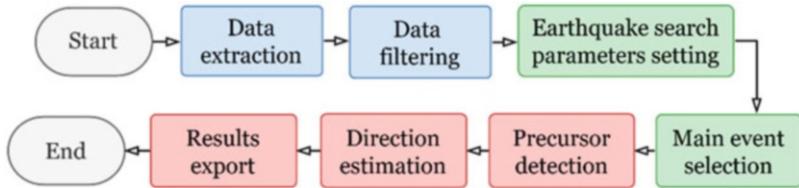

Fig. 5 Flowchart of the software operation

show the incoming signal directions where the color saturation represents the probability, whereas the magenta circles represent the location of earthquakes within the predefined spatiotemporal range. One of the circles that corresponds to the main event is filled. Hence, when the most saturated blue bar overlaps with the filled magenta circle, a high-accuracy direction estimation is obtained. The characteristics of the precursor, i.e., date of appearance, amplitude, frequency range, estimated direction, error percentage of estimation, and lead time, are displayed in Fig. 4l. As an option, the set of information together with the precursor detection and direction estimation plots can be sent to the user's e-mail address (*Send Results* button in Fig. 4m).

The operation flow of the software is concisely visualized in Fig. 5 where the blue, green, and red boxes correspond to geomagnetic field data extraction and preprocessing, earthquake searches, as well as precursor detection and direction estimation functionalities, respectively.

Example of Output

The M5.5 earthquake that struck in the ocean near the east coast of Onagawa, Japan (38.49° N, 141.78° E), on August 29, 2012, 19:05:11 UTC, was chosen as an example of the software output. It was a shallow earthquake with a hypocentral depth of 48 km and located 27 km away from the MAGDAS Onagawa (ONW) station located at 38.40° N, 141.47° E. In reference to the station, the earthquake was located at $\vartheta = 77.89^{\circ}$ from the true north, revolving clockwise. Based on its magnitude and epicentral distance, the earthquake would have generated $K_{LS} = 105$ at the station, as given by (6).

The left axis of Fig. 6a indicates the intensity of the temporal evolutions of Dst (blue line) and ap (red line) indices, whereas the right axis shows K_{LS} of the main earthquake event (filled magenta triangle) and other earthquakes (hollow magenta triangles). Figure 6b depicts the evolution of $P_{Z/G}$ parameter (in 0.08–0.09 Hz) as the black solid line with circle markers and its $\mu + 2\sigma$ threshold as the black dashed line. The marker of $P_{Z/G}$ when it exceeds both $\mu + 2\sigma$ and 1.5 (red horizontal line) is identified as an anomaly (encircled red). Since it did not happen during disturbed periods (red shades), it qualifies as a precursor. Otherwise, it will be ignored as it

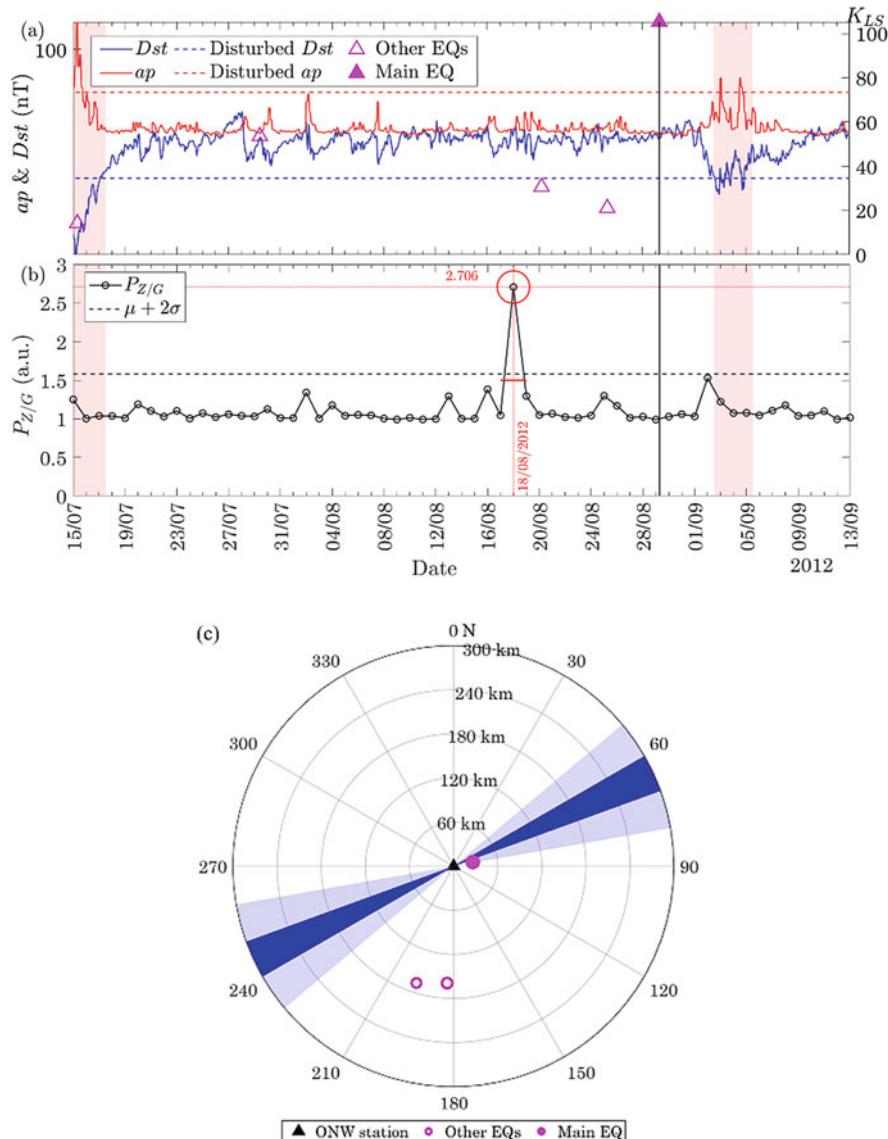

Fig. 6 Temporal evolutions of global geomagnetic indices and K_{LS} in (a) and $P_{Z/G}$ in (b) as well as azimuthal distribution in (c) for the earthquake example

might be a manifestation of solar disturbance in the geomagnetic field. As denoted by the red dotted vertical and horizontal lines in the figure, the precursor of amplitude 2.706 appeared on August 18, 2012, giving a lead time of 11 days before the earthquake.

Azimuthal distribution during the date of precursor appearance is illustrated in Fig. 6c where it is clear that the most saturated blue beam points to 65° and 245° . In addition, the locations of the main and other earthquakes are represented by the filled and hollow magenta circles, respectively. Relative to the actual earthquake location, the estimation had an error of 12.89° (3.581%). The fact that an anomaly which is possibly generated by the earthquake could be observed demonstrates the capability and flexibility of the software, and to an extent the underlying methods, in detecting precursors of moderate earthquakes (i.e., M5.0–M5.9) in addition to strong, major, and great earthquakes. This observation also aligns with the relationship of $r < 40$ ($M - 4.5$), which predicts that an M5.5 earthquake could produce detectable precursors up to 40 km away.

Conclusion

The limitation of conventional seismic methods in predicting earthquakes urges for seismo-electromagnetic approaches, for example, through the observation of ultralow-frequency (ULF) geomagnetic anomalies. In this chapter, precursor detection and direction estimation of the anomalies are applied and extended through the development of a software package. The primary functionality of the software is to automate some of the earthquake precursor analysis steps, of which the processing principles are based on polarization ratio analysis and polarization ellipse methods. As a comprehensive GUI-based software, it provides easy-to-use analysis tools to process geomagnetic field data from its raw, unextracted form to graphical and numerical outputs. Moreover, the software is built to be modular and flexible, in that its functionalities can be used independently in addition to the primary one, for example, as a geomagnetic field data extractor and preprocessor as well as earthquake seeker. The software usage is demonstrated on the M5.5 earthquake that struck Onagawa, Japan, on August 29, 2012. It successfully detected a precursor 11 days prior to the earthquake with a good direction estimation that had an error of just 3.581%. By removing the technical barrier due to sophisticated processing procedures, the software is envisioned to encourage more people to conduct their own analyses using the data that they have access to. Taking it one step further, continuous data streaming could be incorporated into the software, transforming it into a real-time prediction system. This will help relevant government bodies obtain predictions in a timely manner and execute the appropriate plan of action.

Acknowledgments This work was supported in part by the Ministry of Higher Education Malaysia through Universiti Kebangsaan Malaysia under the grant FRGS/1/2020/TK0/UKM/01/1. The authors extend their appreciation to the International Center for Space Weather Science and Education, Kyushu University, for providing the MAGDAS geomagnetic field data. MAGDAS geomagnetic field data are available on request from Akimasa Yoshikawa (yoshikawa.akimasa.254@m.kyushu-u.ac.jp). Global geomagnetic indices and earthquake data are publicly available at www.omniweb.gsfc.nasa.gov and www.emsc-csem.org, respectively.

Abstract

Flood risk is a product of hazard and vulnerability, and is important in managing floods, making decisions, and developing policies. While different approaches can be used to construct these maps, Geographic Information System (GIS)-based maps are increasingly being adopted, which requires researchers to utilize different layers of information. Poorly constructed indices can present misleading messages; therefore, this chapter analyzes existing vulnerability indicators across geographic region and flood type. Moreover, all the indicators are examined for their selection criteria where a priority is given to each, to understand which

indicator is more important than another. These weights were then inputted into a Sankey diagram to easily interpret which vulnerability dimension, indicator, and flood type is of highest priority. While these diagrams will assist researchers with their indicator selection process they will still encounter challenges with data scarcity and outdated data. Therefore, we propose the use of non-traditional data sources like social media to further enhance the flood vulnerability maps, a crucial requirement for crisis responders who need to prioritize their response operations.

Flood · Vulnerability · Indicators · GIS · Social media

Introduction

Climate change is increasing the intensity and frequency of floods around the globe, resulting in huge damages. While flooding causes great disruption to livelihoods and the society, it largely leaves a negative impact on the economy in short- to medium-term context. In order to mitigate the impacts caused by various disasters, the United Nations' Sendai Framework for Disaster Risk Reduction 2015–2030 outlines a strategy based on four guiding principles: understanding disaster risk, strengthening disaster risk governance to manage disaster risk, investing in disaster risk reduction for resilience, and enhancing disaster preparedness for effective response (Asian Disaster Reduction Center, 2015). The first principle emphasizes the need to understand and assess flood disaster risk at various scales (i.e., national and local levels), where the specific sub-goal is to reduce hazard exposure and vulnerability to disasters. There is an emphasis on both hazard and vulnerability together because measuring hazard alone does not provide valuable information to disaster response teams. For example, if a community is located in a flood-prone area and is not vulnerable to a natural disaster, then response efforts should not be prioritized for this specific region. Instead, the limited rescue and response resources can be redirected to highly vulnerable regions which is only possible when disaster risk is taken into account.

Disaster risk is defined as the potential losses, which could occur to a particular community or a society over some specified future time period, where different types of potential losses include lives, health status, livelihoods, assets, and services (United Nations, 2009). Nowadays there is a consensus that risk (R) depends on the interactions between hazard (H) and vulnerability (V), which is generally calculated using the following equation (WBGU–Wissenschaftlicher Beirat der Bundesregierung Globale, 1998; ISDR Terminology, 2004):

$$R = H \times V \quad (1)$$

where R is a representation of the potential for adverse impacts; H is the likelihood of experiencing a certain intensity of a natural or human-induced hazardous event

(i.e., flood, earthquake, or cyclone, etc.) at a specific location; V is a reference to how the exposed elements at risk are vulnerable and susceptible to the adverse impacts of the hazard event.

Interestingly, recent literature has shifted away from vulnerability and began focusing more on resilience as vulnerability deals with the preparedness phase of a disaster, whereas resilience deals with the post-event response and recovery from disasters (Cutter et al., 2014, 2008; Sajjad & Chan, 2019). While there is an open debate about whether resilience or vulnerability should be used, this book chapter focuses on vulnerability as it is widely accepted by international organizations like the United Nations. Equation 1 is widely used for the calculation of disaster risk, but there is still no consensus on how the three factors of vulnerability (V): exposure (E), susceptibility (S), and coping capacity (C) are aggregated and calculated. Most of the debate relies on whether an additive aggregation method (Balica, 2007) (refer to Eq. 2) or a multiplicative aggregation method (Balica et al., 2009; Villordon & Gourbesville, 2014) (refer to Eq. 3) should be used when constructing the vulnerability composites as both methodologies can produce varying outcomes. However, it is noted that as these composites are relative measures of vulnerable aspects of a specific community or society, the outcome and overall essence of the vulnerability is preserved no matter which method is employed for aggregation.

$$V = E + S - C \quad (2)$$

$$V = \frac{E \times S}{C} \quad (3)$$

where V is the function of exposure, susceptibility, and coping capacity; E is the presence of elements such as people, infrastructure, systems, and other elements are subject to potential losses; S is when the exposed elements are susceptible to damage with the occurrence of a disaster event; C is the ability to react to and recover from the effects of a hazard in a timely and manner.

This book chapter focuses on flood-related disasters. This is because, according to a report by the United Office for Disaster Risk Reduction (UNDRR) (UN Office for Disaster Risk Reduction, 2020), floods are the most common type of disaster to occur over a 20-year period of 2000 and 2019, and have affected the 1.65 billion people. Specifically, floods accounted for 44% of all the total 7348 disaster events recorded between 2000 and 2019. Moreover, flood events are anticipated to become more frequent and intense due to the combined effect of population growth and climate change (Gu et al., 2011; Miller & Hutchins, 2017; Saurav et al., 2021). Thus, it is imperative to understand how vulnerability to flooding hazards can be assessed and mapped accurately to assist effective mitigation of potential damages and adaptation to future events.

Examining vulnerability is an integral part of flood risk management (analysis, profiling, and communication) where there lie several approaches within the existing literature for the assessment of flood vulnerability. These approaches include stage damage functions (Papathoma-Köhle et al., 2017; Tarbotton et al., 2015), damage

matrices (Papathoma-Köhle et al., 2017), computer modeling methods (Balica et al., 2013), and vulnerability indices (Barroca et al., 2006; Müller et al., 2011). The first three methods rely on physical vulnerability indicators and neglect other important dimensions like social, economic, and environmental vulnerability, thus making these methods unrepresentative. While indicator-based assessment models are the only method to provide a holistic overview of flood vulnerability (Nasiri et al., 2016) by considering the multi-dimensional factors, it is important to note that these models do not have a specific set of indicators that are universally accepted. This is primarily due to site-specific environmental, socioeconomic, institutional, political, and organizational settings in different areas. Another reason behind this discord is the availability of relevant data on the scale of assessment (i.e., local, sub-national, and national) which is one of the biggest challenges researcher encounter when dealing with data scarce regions. In this context, poorly constructed indices can misrepresent the situation, which could potentially be misleading in terms of decision-making and resource allocation. Therefore, it is necessary to have a clear understanding of all indicators to allow decision and policymakers to set precise targets to reduce vulnerability.

Existing review papers have attempted to assess the different types of indicators involved in constructing vulnerability maps from indicator-based methods. For example, Bigi et al. (2021) analyzed all the socioeconomic indicators and sub-indicators for urban areas only. Moreover, it considered citation count as a criteria to determine the relevancy of indicators. While their study only focused on reviewing one vulnerability dimension for one geographic region, this will only be beneficial to researchers interested in mapping vulnerability in urban regions for socioeconomic vulnerability. Similarly, other review papers either focused on one vulnerability dimension (i.e., Fatemi et al. (2017)) or one geographic region (i.e., Giampieri (2021)). While Moreira et al. (2021a) attempted to focus on all vulnerability dimensions over a set of geographic regions limited to urban, rural, or both regions, it still missed coastal and riverine geologies; and mainly focused on reviewing the different stages involved in the construction of flood vulnerability indices, instead of the indicator selection process. Therefore this chapter first aims to conduct an extensive analysis of indicators belonging to all the vulnerability dimensions across four geographic regions: urban, rural, coastal, and riverine and varying flood type. Moreover, this chapter aims to identify the selection criteria of indicators as indicators derived by experts, household surveys, interviews, and practitioners, which would have higher priority than indicators derived by researchers themselves. This method of distinction is more valuable than citation count and will help researchers easily identify a list of indicators relevant to their study.

This systematic analysis of indices will examine published studies from four different perspectives: (1) vulnerability dimension, (2) type of geographic region, (3) type of flood, and (4) selection criteria. While this evaluation will assist planners, practitioners, and future researchers with their indicator selection process, it will not resolve the challenges of finding relevant data for the indicators in different regions where there is no centralized database for geospatial indicators or when the data sources are outdated. To overcome these two challenges, we introduce the

integration of traditional and non-traditional data sources, which can serve two purposes: (1) replace existing geospatial indicators that are outdated, and/or (2) enhance existing indicators by combining both sources. This will bring about several advantages where firstly the vulnerability maps will be even more accurate as near real-time data from non-traditional data sources is being used to represent the changing vulnerability over time, rather than treating it statically with traditional indicators. Secondly, utilizing the public knowledge through non-traditional data sources is more appealing as it would give a natural distribution of indicators during a disaster where real-time weights can be applied. This is not the case with traditional indicators selected through expert elicitation, which is one of the potential reasons of human bias where individuals are inclined in providing more importance to indicators in line with their specific domain of work.

The remainder of the chapter is organized as follows. Section “[Methodology](#)” details the methodology used to select, screen, and review a specific number of papers for analysis. Section “[Analysis](#)” presents an overview of the indicators analysis for each geographic region. Section “[Non-Traditional Data Sources](#)” introduces a new data source that can be integrated to further enhance flood vulnerability evaluation and profiling through detailed mapping, and section “[Conclusion](#)” finally concludes the chapter.

Methodology

Databases and Search Terms Used

To begin with, a bibliographic search was performed by focusing on studies that produced flood vulnerability mapping through indicator-based methods. For the purpose of this chapter, three different globally known literature databases including Scopus, ScienceDirect, and Web of Science were accessed in February 2022. The authors selected a few tailored keywords that would retrieve highly relevant papers, where the title was considered to narrow down the search space substantially. The following search criteria were used in the Scopus database: TITLE(flood*) AND TITLE(vulnerability) AND TITLE(indicator* OR index* OR indices). This is slightly different from the search performed in Web of Science: Title contains flood* AND Title contains vulnerability AND Title contains indicator* OR index* OR indices, while in the ScienceDirect the following was used in the TITLE: (flood OR flooding) AND vulnerability AND (indicator OR indicators OR index OR indexes OR indices). The search criteria are the same across the three databases, which combined three sub-criteria by the AND operator. Some keywords were included with asterisk (*) so that both the singular and plural forms of those keywords are considered in the search. However, it is noted that only Scopus and Web of Science databases supported such operation. Moreover, some keywords are separated by an OR operator to include the various derivations of the term “indicator” used within flood vulnerability literature. This systematic search resulted in 90 papers from Scopus, 134 from Web of Science, and 18 from ScienceDirect.

Paper Selection Process

An open search was conducted across all three bibliographic databases with no date limit which elicited 243 papers in total. A set of filtering options was used to ensure that the papers belonged to the (1) final publication stage and was an (2) article or book chapter. Only articles and book chapters written in (3) English language and (4) contained in journals and books were included for the evaluation presented in this chapter. This initial filtering stage reduced the number from 243 papers to 175, where duplicate removal was then applied to retrieve a unique set of 92 papers published between 2006 and 2022. These 92 papers were then manually screened based on the title, abstract, and keyword, to remove irrelevant papers that were not useful for the purpose of this review. A set of inclusion criteria was used during the manual screening stage where papers focused only on (1) flooding, (2) community-based flood vulnerability, and (3) vulnerability indicators were selected to be included. Similarly, a set of exclusion criteria was set to remove papers that focused on (1) multiple hazards, (2) climate change or sea level rise, and (3) other vulnerability topics such as building or agriculture vulnerability. This manual screening step reduced the number of papers from 92 to 32, where the full text of the 30 open access papers was then reviewed in detail. Figure 1 provides an overview of the search and selection process where the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) (Tricco et al., 2018) flow diagram was used.

Analysis

The 30 papers were first examined for three main characteristics including region type, flood type, and selection criteria, where each characteristic is detailed below.

Region Type In this study, we categorize the papers into four broad regions based on the area of interest they focused their analysis on. These regions include urban, rural, coastal, and riverine. Urban regions are characterized with a high population density with features of a built environment. This is completely opposite to rural regions which are comprised of lower population settlement and large amounts of undeveloped land. Coastal zones consist of areas between land and sea and come in different features like cliffs, beaches, and mudflats. With respect to river floodplains, this consists of large flat land occurring on either side of rivers.

Flood Type A distinction can be made between the four most common types of floods: urban floods, flash floods, coastal floods, and river floods. Urban floods tend to result from the accumulation of extreme local rainfall, which causes blocked drainage systems. Flash floods can result from intense rainfall, dam failures, or the sudden release of water from ice jams which often occur over a small geographic area and causes huge damage. Coastal floods occur when storms coincide with high tides or from high tidal waves created by tsunamis, hurricanes, or tropical storms. River floods are a result of increased water flow from rainfall that causes overtopping of the banks, thus spilling water onto the surrounding land.

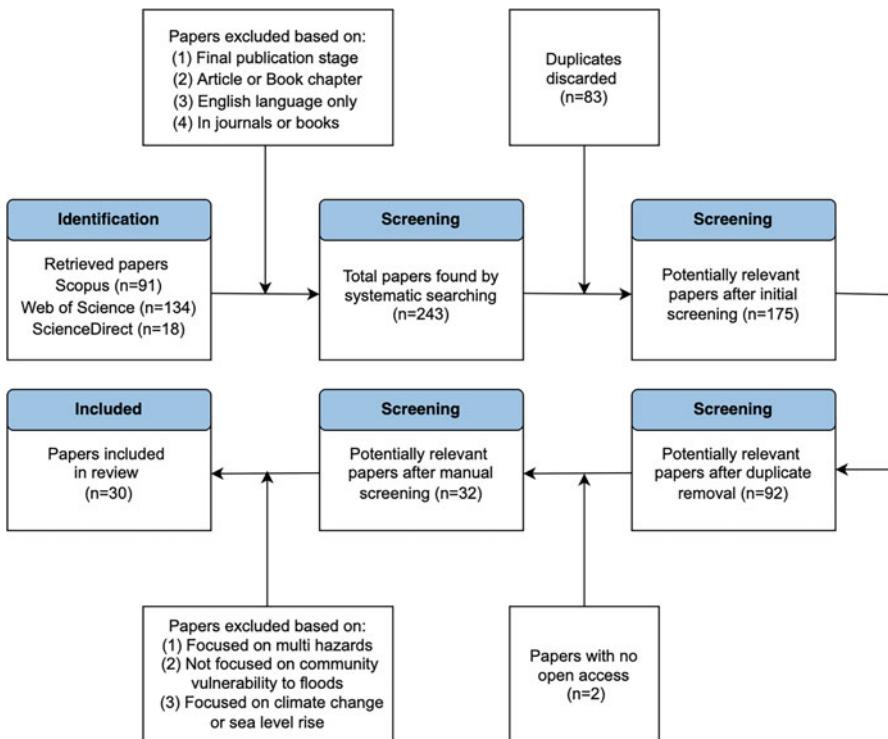

Fig. 1 Flow diagram of the search and selection process based on PRISMA

Selection Criteria Indicators can be selected from a variety of sources where some studies have conducted interviews and surveys with local households to understand which indicators are relevant and how they contribute to increase or decrease the vulnerability. Other researchers rely on conducting Delphi surveys to understand the opinions of experts and practitioners in the field of flood management. Other than interviews, questionnaires, and surveys, which are all primary data, some researchers have relied on secondary data by consulting the published literature to identify the commonly used indicators relevant for their area of study.

Table 1 shows the final 30 papers organized by region type where each paper was then examined for flood type and source of indicators selection. It is evident that a large proportion of these papers belong to the urban region, while the remaining rural, riverine, and coastal regions have almost similar number of fewer papers. These statistics show that researchers are increasingly focusing on examining flood vulnerability across different urban regions. The potential reason for this focus could be the higher exposure of urban areas to flooding along with the likelihood of largest impact and damage due to higher population and capital investments in cities. The next step involved analyzing all the indicators by region type with different vulnerability dimensions in mind. A detailed list of all the indicators can be found in the Appendix.

Table 1 Overview of 30 papers categorized by selection criteria and flood type

	Number	Selection criteria	Flood type	Reference
Urban	1	Literature	Flood	Baeck et al. (2014)

	2	Researcher	Flood	Martinez-Graña et al. (2016)
	3	Researcher	Coastal flood	Tao (2021)

(continued)

Table 1 (continued)

	Number	Selection criteria	Flood type	Reference
	4	Household survey and stakeholder survey	Riverine, coastal, and urban	Bernadel et al. (2016)
	5	Literature	Coastal flooding	Giannakidou et al. (2019)
	6	Literature	Flood	Giampieri (2021)

Table 2 The priority list developed for weighting the different selection criterion's

Selection criteria	Priority	Description
Household survey or interview	6	This involves surveying the affected locals in flood-prone areas
Stakeholder or organizational engagement	5	This involves collecting data from organizations and stakeholders
Expert questionnaire or focus groups	4	This involves collecting data from experts in the disaster domain
Statistical analysis	3	This involves using statistical techniques to get relevant indicators
Literature	2	This involves conducting a literature review of the indicators used
Researcher	1	Researchers use their GIS knowledge to include relevant indicators

While this comprehensive list of indicators is a good starting point for researchers in the field of flood vulnerability assessment and mapping, they will still struggle to understand which indicators should be prioritized. To tackle this problem, we devised a priority list as seen in Table 2 where we assigned the highest priority score (6) to indicators that are derived by surveying or interviewing individuals in flood-prone regions. This first-hand information is highly valuable and is the most representative of the vulnerability situation of a community at the highest possible resolution. The second highest priority (5) includes indicators collected from interviewing or surveying key stakeholders or governmental/non-governmental organizations in the disaster response and recovery phase. The next priority (4) relates to gathering insights from experts who have been in the domain of disaster risk reduction, whether that is being part of research institutes or educational institutes. After this, the priority score (3) is given to indicators that are proven to be statistically significant for the past researchers area of interest, where common techniques include the Analysis of Variance (ANOVA) and the Principal Component Analysis (PCA) conducted by different researchers. The second last priority score (2) relates to indicators that were collected by consulting past flood vulnerability literature, which is already published after the formal peer-review procedures. Finally, the lowest priority (1) is given to indicators derived by researchers themselves and can introduce bias if the researcher is not very knowledgeable or experienced in this field.

Urban Region

All the indicators from the 17 papers were analyzed and consolidated, to create a final list of 60 indicators, which belonged to either social, economic, or physical vulnerability dimensions. In particular, 30 indicators belonged to social vulnerability, 11 to economic vulnerability, and the remaining 18 to physical vulnerability. For effective communication and to visualize these indicators appropriately, the Sankey diagram is used to present the flow of indicators in relation to both vulnerability dimension and flood type, as presented in Fig. 2. The thickness of the lines represents the weight given to each indicator based on the selection criteria involved. In cases where an indicator has multiple selection criteria, an average of the priority weights is taken. These weights are reflected in the diagram which is separated by a colon.

Figure 2 shows the social vulnerability indicators for urban regions, where all 30 indicators have similar weights between 2 and 4 indicating that all of them are commonly used. Within urban regions there exists different types of floods, and the greatest emphasis can be seen on flash floods, river floods, and flooding in general.

Figure 3 displays the economic and physical vulnerability indicators, where the overall weight of the physical dimension is greater than economic but less than social vulnerability. With regard to the economic dimension, the majority of the indicators are applicable to coastal flooding, river flooding, and urban flooding, whereas for physical vulnerability, most of the indicators are used in river flooding scenarios.

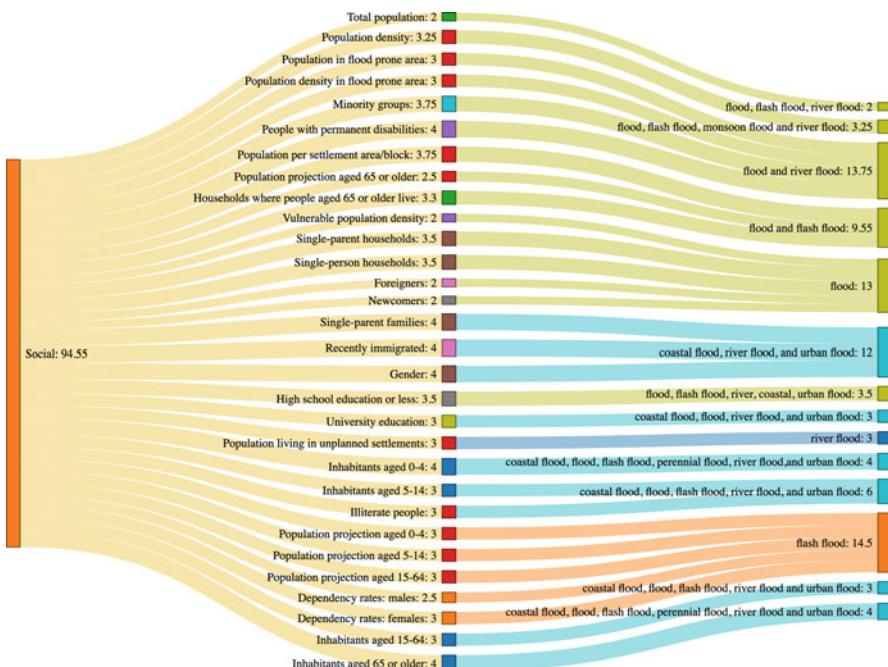

Fig. 2 Overview of social vulnerability indicators for urban regions

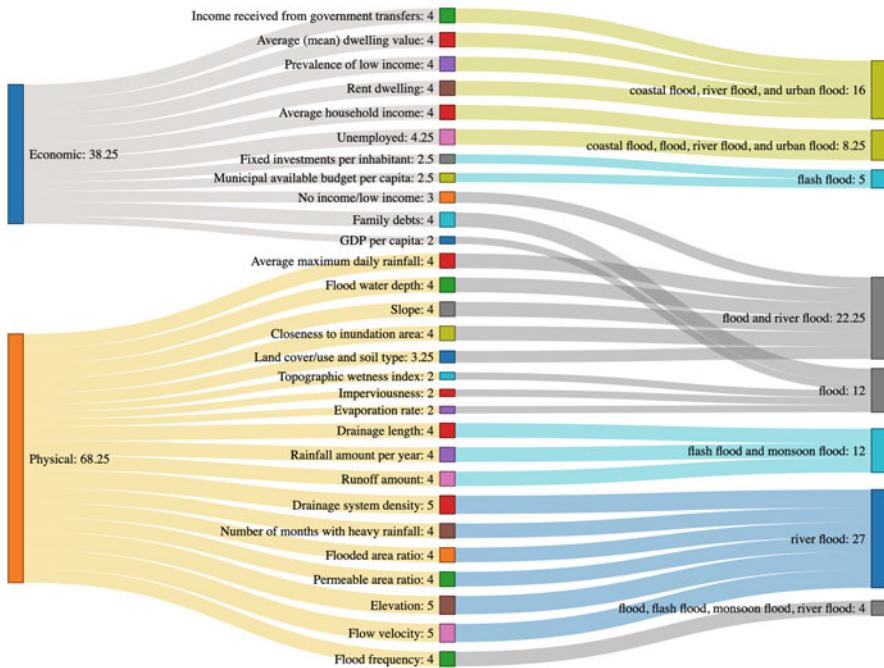

Fig. 3 Overview of economic and physical vulnerability indicators for urban regions

Rural Region

For rural regions, indicators are spread across four dimensions with physical vulnerability being the highest priority followed by ecological, environmental, and political vulnerability as seen in Fig. 4. All 35 indicators either belonged to general flooding and river flooding where flood-related indicators have a combined overall weight higher than river flooding indicators. Only the environmental vulnerability indicators are used in river flooding scenarios while the physical, ecological, and political indicators are spread across general flooding and river flooding.

Coastal Region

Figure 5 visualizes all 71 indicators, which are distributed across physical, institutional, social, and economic dimensions. Interestingly, 47% of the indicators for flood vulnerability assessment over coastal regions belong to the physical dimension only. Within the physical dimension, three indicators have higher priority than the rest, which include frequency of flooding, height of flooding, and number of cyclones/typhoons. These three indicators are applicable to coastal flooding, river flooding, and urban flooding. Next, the institutional dimension has six indicators with the same weights, which can be used in general flooding scenarios. Coming to the social dimension which is the second most important dimension after physical vulnerability,

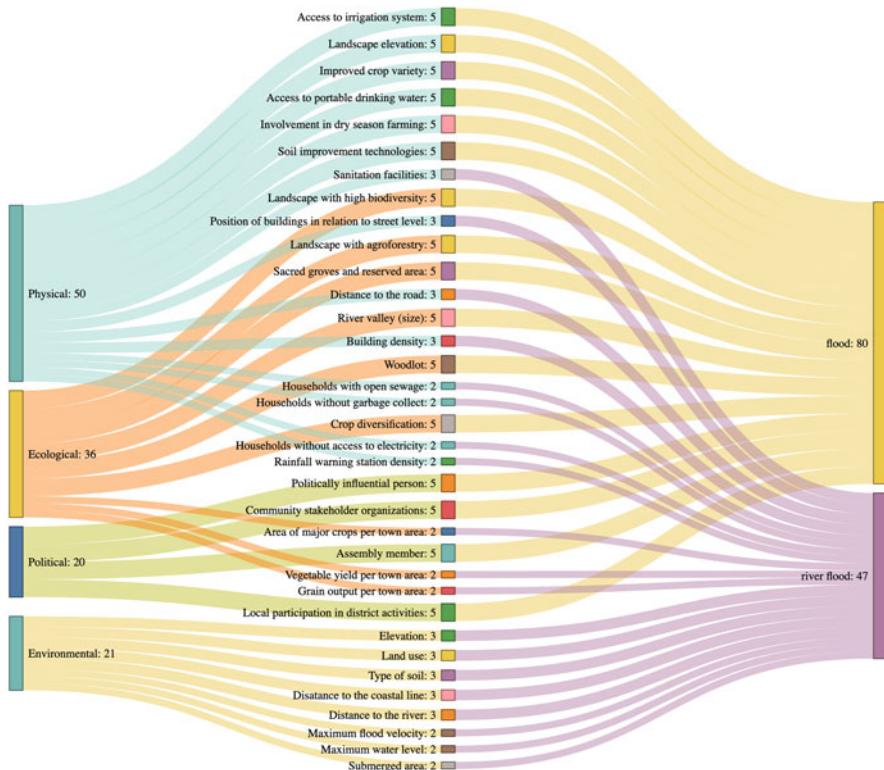

Fig. 4 Overview of physical, ecological, political, and environmental vulnerability indicators for rural regions

we see that five indicators in particular have greater priority over the others including housing conditions, houses with no access to improved sanitation, houses with no access to an improved water source, presence of rats in the vicinity, and presence of waterlogged areas in the vicinity. While data for these five indicators can be gathered only through first-hand information from locals, researchers who cannot collect this information will not be able to include these indicators in these studies. Thus, there is a need for introducing non-traditional indicators, which can be incorporated into the vulnerability assessment and profiling, as a proxy of these traditional indicators collected through primary data sources. Lastly, within the economic dimension, there are two indicators applicable to coastal, river, and urban flooding which should be given importance, and this includes family income and property insurance.

Riverine Region

In total there are 49 indicators applicable to rural regions which either belong to the social or economic dimension. Similar to the other regions, the social vulnerability indicators have almost similar weights as all of them are commonly used by

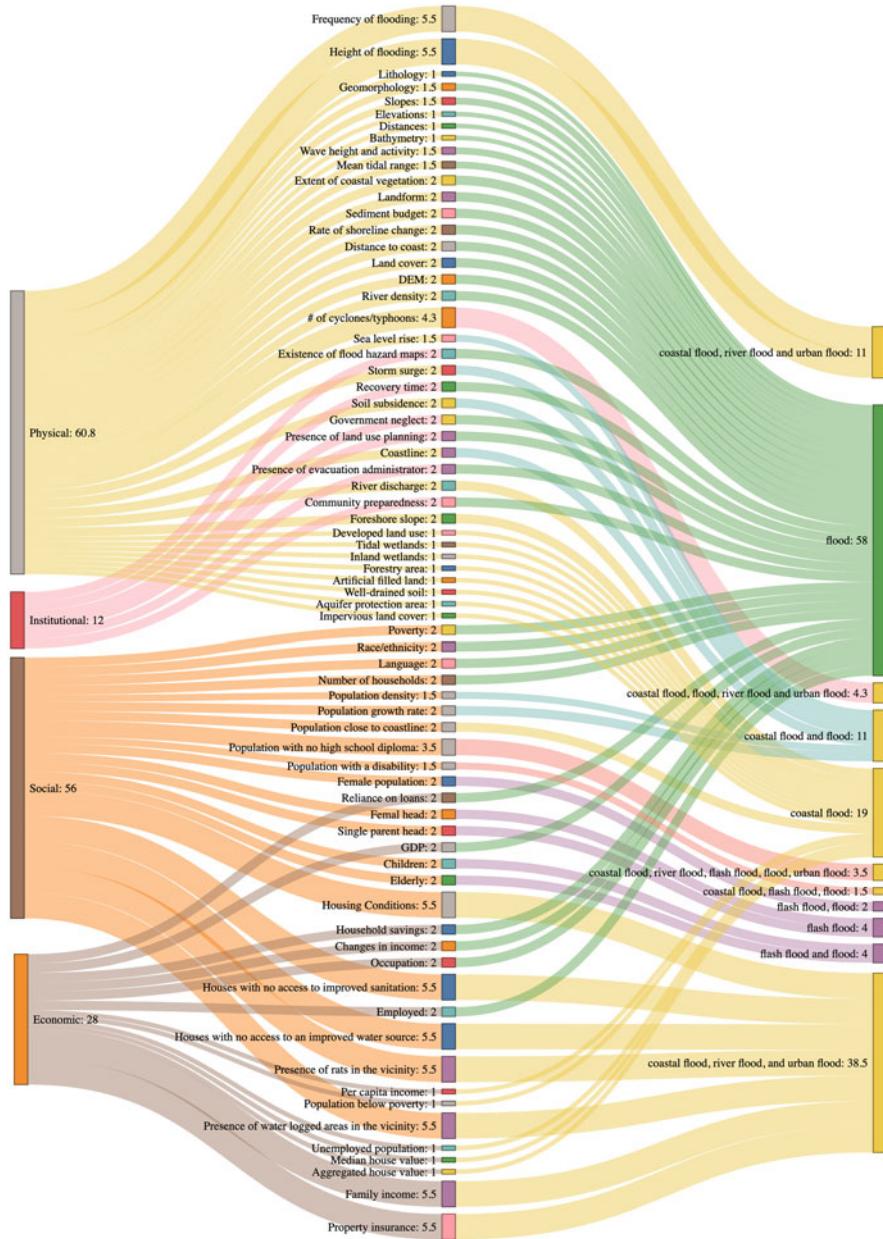

Fig. 5 Overview of social, economic, physical, and institutional vulnerability indicators for coastal regions

researchers, where most of these indicators are used in studies examining flash floods in riverine regions. Coming to the economic dimension, there is one indicator that stands out amongst the rest which is fixed investments per inhabitant which has a

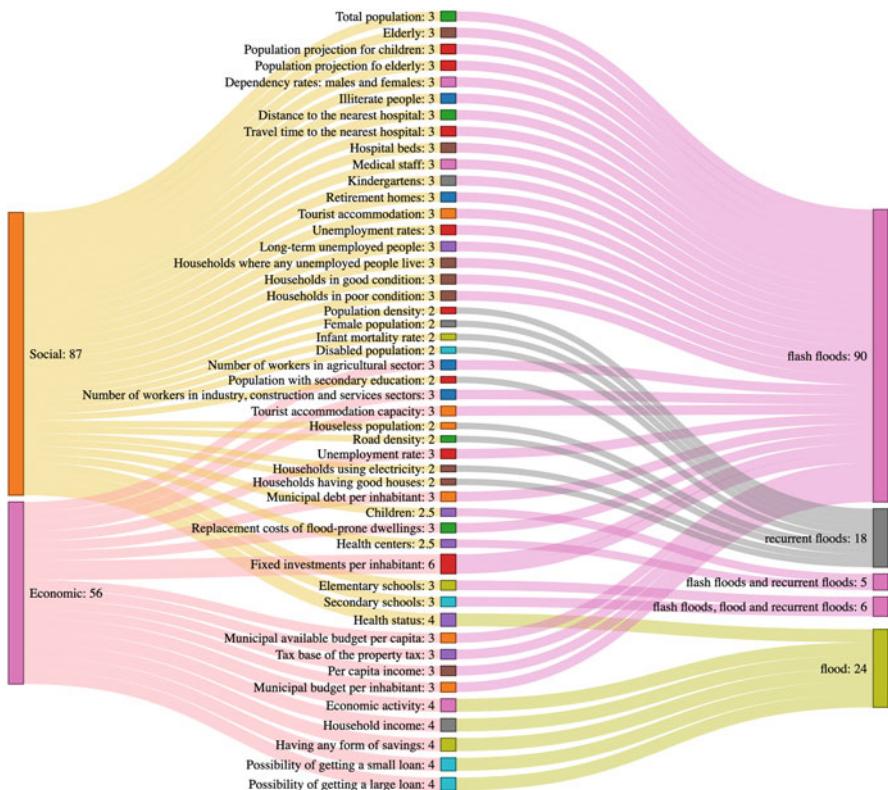

Fig. 6 Overview of physical and social vulnerability indicators for river regions

weightage of 6. Almost 75% of the indicators are applicable to flash floods while the remaining can be applied to general flooding scenarios (Fig. 6).

Non-Traditional Data Sources

Volunteered geographic information (VGI) refers to the creation of user-generated information, which has been disseminated voluntarily by individuals (Goodchild, 2007). During an onset of a disaster, social media, in particular, acts as a VGI platform to deliver real-time geospatial information about the disaster with the help of geolocation features. Provisioning of such kind of information can progressively help inform response teams about the location of affected people who need assistance so that rescue and relief operations can be directed in an efficient and informed manner. Similarly, decision makers will be able to make smart as well as more informed decisions around deploying resources for recovery operations as they would have a better situational awareness of the disaster, which would not be possible otherwise. This ability of VGI platform-based information has an upper hand as compared with traditional data sources, which are static in nature and are mostly outdated due to

carrying out the surveys well before or after the disaster event. Hence, leveraging the power of VGI platform-based data to formulate non-traditional vulnerability indicators has a wide scope, particularly for near-real-time situation awareness and assessment of vulnerability assessment in data-scarce regions (i.e., developing countries).

While social media platforms like Twitter harness the local knowledge and provide the advantage of filling in the information gap during a disaster event, there comes the drawback of the quality and reliability of this information. Nevertheless, this type of information is continuously being explored in the domain of flood management, where several studies have explored the potential use of Tweet text and images in producing flood extent maps and damage assessment maps, identifying local hotspots, and examining the spatial variation in social media activity during a disaster (Bono et al., 2022; Cervone et al., 2016; Amir Masoud Forati and Rina Ghose, 2022; Kersten & Klan, 2020; Yuan & Liu, 2018). However, there still lies a gap in this domain, where no studies to the best of our knowledge have utilized social media information for the enhancement of indicator-based flood vulnerability maps, which could provide opportunities to direct efforts for the mitigation of vulnerable aspects during an emergency situation. This is because the data sets utilized in the construction of indicator-based flood vulnerability maps are always static where some indicators rely on outdated information sources, such as national census data. Moreover, finding indicator-related data sources can become challenging in data scarce regions like small island states and developing countries where no centralized data management infrastructure is available. To overcome these limitations, user-generated information from social media can be introduced into the flood vulnerability index to provide an enhanced overview of the flood situation in near real-time to benefit response teams.

Social Media Indicators

Social media indicators for flood vulnerability mapping can be used in two different ways: (1) replace existing geospatial indicators or (2) enhance existing geospatial indicators by introducing proxy social media indicators. The first scenario is applicable when traditional indicators are hard to find in data scarce regions or when there is no access to experts or local knowledge in order to get data for these traditional indicators. The second scenario is applicable when traditional indicators exist but are outdated making it unrepresentative and thus there is a need to use up-to-date non-traditional data sources. Therefore, the first step is to understand what type of social media indicators can be used to proxy for the traditional indicators.

For this, a recent study that explored the fusion of remote sensing and social media for flood mapping provided insights into three different types of contextual information evident from social media text and images (Sadiq et al., 2022). This includes Needs and Requests, Impact Assessment, and Situational Awareness reports as seen in Table 3. For example, if a researcher is focusing on a coastal region and is interested in using social vulnerability indicators like “Houses with no access to improved sanitation” as seen in Fig. 5 and they cannot find data for this indicator, they can refer to the Situational Awareness section and see the proxy indicator for “Population without access to sanitation hygiene” which is “NO. of sanitation and hygiene reports.” These

Table 3 Overview of traditional indicators and its proxy non-traditional indicators

	Traditional indicator	Non-traditional indicator
Needs and requests	Population under poverty	No. of monetary aid requests
	Persons with disabilities	No. of disability item requests
	Lost family members	No. of rescue requests
	Population without access to food and water supply	No. of food and water requests
	Human health	No. of medical assistance requests
	Shelters	No. of shelter requests
Impact assessment	Household without sewage disposal system	No. of water system and sewage damage reports
	Household without electricity	No. of electricity damage reports
	House damage value	No. of infrastructure damage reports
	Crop lost value	No. of agriculture, crops, livestock damaged
	Damages to public utilities	No. of utilities damage reports
	Unplanned waste deposits	No. of pollution and contamination reports
Situational awareness	Population affected	No. of affected individuals
	Population in flood area	No. of affected areas
	Household member with illness	No. of health and disease-related reports
	Crime rate	No. of safety and security-related reports
	Population without access to sanitation and hygiene	No. of sanitation and hygiene reports
	Warning system	No. of weather information and updates
	Warning system communication penetration rate	No. of cautionary/advice reports
	Awareness	No. of donations and volunteering reports
	Dependency on public infrastructure	No. of logistics and transportation reports
	Flood insurance	No. of insurance reports

reports can come from either social media text or images which are geolocated with relevant classifier information, where the following approach can be used:

Traditional and Non-Traditional Indicators

1. Collect social media text and images available in the area of interest that has been affected by a flood event. For example, with the Twitter platform the Artificial Intelligence for Disaster Response (AIDR) system (Imran et al., 2014) can be

used to automatically trigger the collection of tweets based on a geographic region and/or a set of flood-related keywords.

2. Geo-tag as many social media posts as possible. For example, the methodology proposed in (Qazi et al., 2020) can be used to assign city, county, state, and country information to tweets based on various metadata fields like geo-coordinates, user location, place, user profile description, and tweet text.
3. Filter out irrelevant social media texts by passing the social media posts through text classification models. For example, CrisisDPS (Alam et al., 2019) can be used to classify tweet texts based on disaster type, informativeness, and humanitarian information. Social media texts classified as “flood,” “informative,” and any relevant humanitarian category can then be considered.
4. Filter out irrelevant social media images with the help of image classification models. For example, the disaster type prediction model proposed by Weber et al. (2020) can be used to extract images classified as “heavy rainfall” and “flooded.”

Once relevant geolocated social media text and images are collected, the next step involves deciding how to aggregate the information presented in these point data instances. Such aggregation could be made using the imaginary boundaries (i.e., grids with specific resolution – 30, 50, or 100 m) or over the localized administrative boundaries of the region of interest. While both have their own advantages and shortcomings, the utilization of administrative boundaries has an upper hand as it can effectively inform the stakeholder and professionals working in the field of flood management. The use of administrative region makes it easy to communicate the outcome as people are familiar with these names as compared with grids that are assigned assumed codes for reference. There exists three different aggregation techniques within literature which include using an additive or multiplicative approach (Sajjad, 2021; Sajjad & Chan, 2019), mode approach (Sajjad et al., 2020), or rates approach. Below we describe how each method can be used to create flood vulnerability maps using social media indicators:

1. **Sum:** In order to show the intensity of each dimension (i.e., needs and requests, Impact assessment, and situational awareness), the aggregation of relevant tweets using a simple sum could be used (i.e., the additive approach).
2. **Multiplicative:** In order to show the intensity of each dimension (i.e., needs and requests, Impact assessment, and situational awareness), the aggregation of relevant tweets using a multiplicative method could be used.
3. **Mode:** In order to evaluate all aspects, the proportion of each dimension within the total tweets can be used to aggregate for a specific administrative boundary.
4. **Rate:** In order to show the dominant dimensions as well as to evaluate the rates of different dimensions, the population weighted aggregation method can be used.

It is noted that as the resultant vulnerability maps represent a relative measure, utilization of any aggregation method will suffice. Once the aggregation method is selected and applied to the social media points, the output layer can then be used as part of the final flood vulnerability map construction. Additionally, such maps can

further be used to identify the patterns and trends, if any, in flood vulnerability by the application of several spatial information models. However, this would require proper understanding, skills, and additional resources.

Conclusion

This study analyzed 30 indicator-based flood vulnerability assessment papers to holistically understand the different indicators used across four region types: urban, rural, riverine, and coastal regions. All the indicators were categorized among common vulnerability dimensions and to understand which indicator within a dimension should be given importance, a priority list was devised in order to apply weights to each indicator depending on which selection criteria was used in deriving the indicator. For example, indicators collected through household surveys and interviews were given the highest priority as it is highly representative of the locals in flood-prone areas unlike indicators gathered by researchers who do not have knowledge of the reality, thus making researcher-derived indicators the lowest priority. These weights were then applied to all the indicators and were inputted into the sankey diagrams where the thickness of the line represented the weight. These diagrams revealed several insights such as which vulnerability dimension is more important than others, which indicator within a dimension has higher priority over others, and finally which type of flood is most commonly used for flood vulnerability assessment. While these findings would assist researcher with their indicator selection process, they are bound to encounter challenges with finding data for some of these traditional indicators, especially for data scarce regions or when the data is outdated. Thus, we propose that non-traditional data sources like social media should be used as proxy indicators to either replace or enhance traditional indicators, where we provide a step-by-step approach to achieving these flood vulnerability maps through the aggregation of social media point data.

Abstract

In the past decade, the southern rim of the Himalayas experienced several anomalous weather events such as cloudbursts, extreme precipitation, flash floods, and avalanches due to a changing climate. The topography and orography process of the Indian Himalayas facilitates a favorable condition to cloudbursts. These events mostly appear during the monsoon period and are elusive corresponding to their geographical position and associated impacts due to a lack of monitoring and data observations. The sudden downpour of rainfall in a range of 100–250 mm/h in a short span covering a smaller spatial extent similar to 1 km² is typically defined as a cloudburst event. On the other hand, according to the India Meteorological Department, if the rainfall occurs more than 100 mm/h

with strong winds and lightning over an area of 20–30 km² is termed a cloudburst. Interestingly, the elevation band where the occurrence of such events is frequent lies between 1000 to 2000 m which are densely populated valley folds of the Himalayas. Some studies derived that mostly cloudbursts occur and are expected to occur in low elevation high-temperature zones of topoclimate regimes of the Himalayas which receive low rainfall and exhibit high land surface temperature ranging from 18° C to 28° C in July and August. This study provides a comprehensive understanding of the physical driving processes such as atmospheric circulations, thermodynamics, orographic lifting, and its distribution based on analytical and geospatial approaches to know the triggering factors of cloudburst events and invigoration of the convection process.

Keywords

Himalayas · Cloudburst · Precipitation · Extreme rainfall · Land surface temperature

Introduction

The Himalayas is the third biggest snow cover and ice deposition region and provides freshwater to 1.3 billion population living in the lowlands of river basins of Indus, Ganga, and the Brahmaputra (IGB) covering eight countries (Afghanistan, Bangladesh, Bhutan, China, India, Myanmar, Nepal, and Pakistan) (Qazi et al., 2020). The Himalayan cryosphere has a significant role in tributaries of these river basins and indispensable character to river runoff in terms of livelihood (Qazi et al., 2020). Indian Himalayas play a crucial role in the supply of essential water resources and drive several rivers in India that originate from them. The Indian Himalayas exhibit a multitude of glaciers which act as water towers (Bandyopadhyay, 2013). The region has a significant role in regulating the climatic conditions of northern India as well. The topography of these mountains is known to trap the moisture content (summer monsoon) that triggered precipitation primarily in the form of rainfall and snow.

Considering the significance of the Indian Himalayas for the regional regime, it is vital to discuss the impending natural hazards that occur frequently in this region. The Indian Himalayas have witnessed several natural disasters like extreme rainfall, cloudburst, flash floods, earthquake, landslide, and avalanches (Sati, 2018). Extreme rainfall is most frequently seen in this region that facilitates flash floods and landslide. Kedarnath flash flood in 2013 was a classical example of extreme rainfall and cloudburst events that caused severe damage of life and property (Sikka et al., 2015). In the past few decades, cloudburst events and associated flash floods have been reported in the middle Indian Himalayas (Mishra et al., 2021). These cloudburst events have severe spontaneous impacts on the loss of lives, agriculture, and infrastructure (Thayyen et al., 2020). One of the major cloudburst events that affected more than 200 humans and 33 houses in terms of death and property

damage was on 20 July 1970 in Ganai village of Almora (Joshi & Kumar, 2006). In August 2010, the surrounding rim of Leh city experienced a devastating flash flood due to massive cloudburst events which have resulted in 255 dead bodies (Thayyen et al., 2013). The impact of these flash floods covered a 100 km radius surrounding Leh and demolished various infrastructures such as roads, bridges, hospitals, and national highways. Almost 52 villages and 1749 houses were affected due to this flash flood (Thayyen et al., 2013). Similarly, in August 2012, a flash flood occurred in the Asi Ganga tributary of Bhagirathi due to a massive cloudburst. Approximately 35 people and 436 livestock were missing and 12,000 people and 250 houses were affected due to this extreme event (Mishra et al., 2022). Furthermore, there was property damage of 612 crores (Vikram et al., 2013). Recently, a cloudburst event was captured using remotely sensed spaceborne rainfall data and satellite imagery on 12 June 2018 over the mountain ridge of Trisha Village of Nubra valley in the Ladakh region (Thayyen et al., 2020). Moreover, this cloudburst event covered a much smaller spatial extent less than 1km² and also triggered a flash flood. There were 57 cloudburst events that have been reported from 2010 to 2020 in the upper Ganga basin (Mishra et al., 2022) and 30 events from 1990 to 2016 in the Indian Himalayan region (IHR) (Dimri et al., 2017).

Climate change has developed to be a basis for an aggravated occurrence of such events and is bringing several challenges globally due to increased temperature influencing these extreme events which trigger severe disasters that have resulted in loss of lives and infrastructure. Recently, ice rock avalanche in Chamoli district of Uttarakhand due to warm permafrost, changes in seasonal snow pattern, shifting rainfall, and land surface temperature are such an indication of climate change (Thayyen et al., 2021). In the past few decades, the alterations in precipitation patterns are a clear indication of climate change, and the driving factors for these changes are not comprehensively defined yet (Kumar et al., 2018). The orographically locked system of IHR and its interaction with monsoon provide the required conditions for extreme rainfall and cloudburst events (Thayyen et al., 2013, 2020; Dimri et al., 2016, 2017). The IHR regions are categorized in four topoclimate regimes with the low elevation high temperature being one of the most hazardous topoclimate zones due to a frequent recurrence of these events (Mishra et al., 2022). In general, thermodynamically unstable atmosphere carrying high moisture content and heat (due to tropical origin) has resulted in high-intensity rainfall which may often transpire into a cloudburst (Kelsch et al., 2001; Grunfest & Handmer, 2001; Woolley et al., 1946). This cumulonimbus cloud is stuck in vertiginous topography by local convection (Dimri et al., 2017; Das et al., 2006; Deoja et al., 1991; Upadhyay, 1995). The combination of southwest monsoon and western disturbances leads to high-intensity rainfalls during the early monsoon over IHR (Thakur, 2000; Ray et al., 2015). In the recent past year, the cloudburst events that occurred during pre-monsoon (May, June) were seen in Ladakh and Karakorum regions (Dimri et al., 2017).

Cloudburst events are influenced by the topographic control, particularly the elevation (Mishra et al., 2022). Research demonstrates that the annual rate of temperature is much higher than the average global temperature over the Indian

Himalayan region (Reay et al., 2007). Hence, there is a direct relationship between extreme events and climate change (Krishnan et al., 2019). Many studies referred to cloudburst events as short lived and occurred at localized area (Thayyen et al., 2020). However, as per IMD parlance, cloudbursts are characterized by rainfall rate of more than 100 mm/h over a geographical area of 20–30 km² (Dimri et al., 2017). The recurrence of cloudburst events has been widely observed over smaller areas in the lower IHR. However, these events have only been reported at locations comprising the requisite field technology for recording cloudburst events. Further, such locations are few, and development in approaches to sense remotely the occurrence of such events is highly sought. Additionally, the non-cyclic pattern of these cloudbursts and associated moisture amount is yet unknown (Kumar et al., 2018).

The driving forces to facilitate these events comprise a complex convective system, mesoscale thunderstorms, and orographic processes (Kumar et al., 2018). The accompanied dynamics, thermodynamics, and orographic interaction to the formation of cloudburst are still missing (Dimri et al., 2017). Subsequently, a proper definition of cloudburst is yet not evident due to the complex weather convection processes and insufficient hydrometeorological data and associated investigations. Several studies suggested that climatic variability has a significant character to lead to extreme events. The variability of the Indian summer monsoon in terms of atmospheric circulations and teleconnection such as ENSO, NAO (El Nino Southern Oscillations, North Atlantic Oscillations), etc. plays a paramount role for hydrological extreme events (Sun & Wang, 2012). Dimri et al. (2017) suggested understanding the associated factors like physical and dynamical phenomena for cloudburst events.

About the Indian Himalayan Ranges

The Himalayas is one of the world's loftiest and younger mountain ranges which covers approximately 25,000 km from Indus valley beyond the Nanga Parbat in the west to Namcha Barwa in the east (Roy & Purohit, 2018). The Himalayan topography is highly rugged and sharp at west to Sulaiman Kirthar ranges (Roy & Purohit, 2018). Due to the historical and numerous occurrences of cloudburst events in the states of Uttarakhand, Himachal Pradesh, and Union Territory (UT) of Jammu Kashmir and Ladakh, we primarily focus our study in these regions of IHR. The spatial extent of the mentioned region lies between 28.72° to 37.09° N and 72.51° to 81.04° E. The IHR exhibits significant variation in terms of the vivid climatic conditions and elevation. Figure 1 illustrates the variation in the elevation from as low as 184 m to 8.56 km a.s.l based on the 30 m Shuttle Radar Topography Mission (SRTM) – digital elevation model (DEM). This region covers approximately a geographical area of 333,848 Km², and the dominant topography is mountainous. The entire area is classified into three precipitation regimes which are monsoon dominant, monsoon deficit, and precipitation transition zone (Yadav et al., 2020).

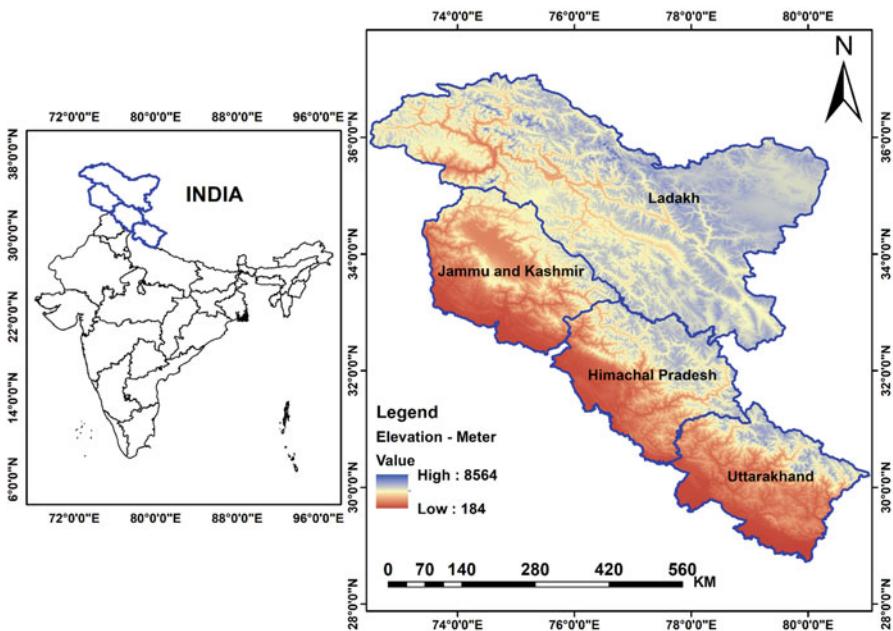

Fig. 1 Study region showing the states and elevation of the region based on the Shuttle Radar Topography Mission (SRTM) digital elevation model (30 m spatial resolution)

Topography and Cloudburst Distribution over IHR

Topography is an important factor for understanding the orographic processes over the Indian Himalayan region where elevation is one of the necessary criteria. The topography has influence the patterns of precipitation at global and regional scale (Smith, 1979). The rugged terrain of mountain affects the flow of air and disturbs the vertical stratification of the atmosphere and acts as barriers (Barros & Lettenmaier, 1994). Anders et al. (2006) suggest that there is direct relationship between the spatial pattern of the precipitation and topography.

In this context, the Shuttle SRTM-DEM at 30 m spatial resolution has been used for the classification into eight elevation bands for the identification of the cloudburst distributions, as shown in Fig. 2. Extreme rainfall and cloudburst events were commonly observed during the peak monsoon season; when the cumulonimbus clouds are trapped in the steep rugged terrain of the Indian Himalayas, it provides suitable condition for heavy downpours of water through extreme rainfall (Thayyen et al., 2020). The elevation also has a significant role in such events (Thayyen et al., 2013). The distributed pattern of the southwest monsoon is developed due to local relief and the topography of the Himalayas. The topographic controls termed as two-step topography have an indispensable role in the spatial extent of monsoon rainfall over the Himalayas. The majority of cloudbursts take place in this two-step

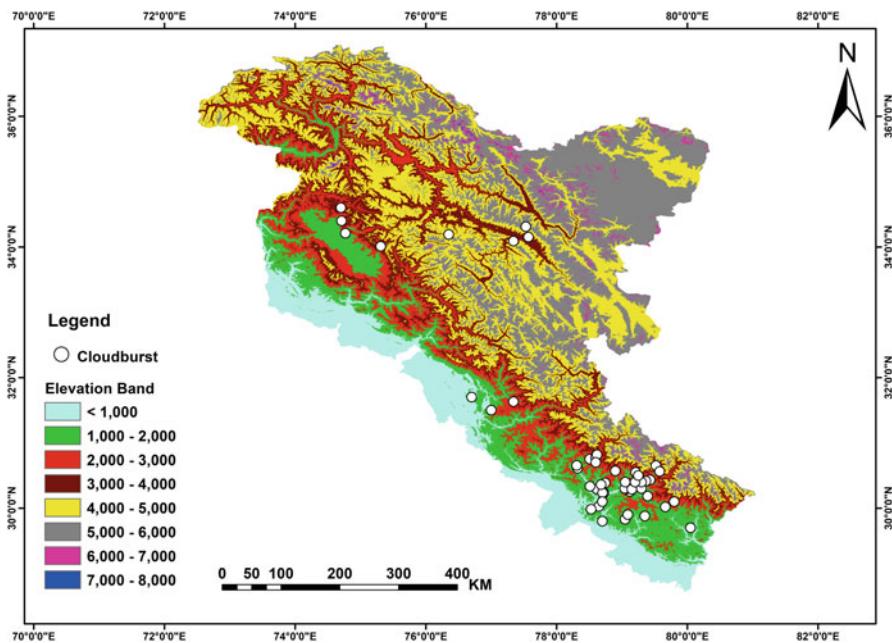

Fig. 2 Elevation bands (1 km interval) from below 1 km to 8 km in the Indian Himalayas and associated cloudburst distribution shown in white dots concentrated majorly in Uttarakhand (lower part of the map)

topography (Mishra et al., 2022). Hence, the identifications of elevation control bands are mandatory for the assessment of cloudbursts. In many studies, it is found that the 1000 to 2000 m elevation band is the most favorable place for such events in the entire Himalayas. These elevation bands have the most populated villages which are most vulnerable to cloudburst, flash flood, extreme rainfall, and livelihood vulnerability index (Mishra et al., 2021). Therefore, the future occurrence of cloudbursts in these critical zones would have massive impact in terms of human fatality and economic loss.

Cloudbursts Categorization and Historical Studies

Categorization of Cloudburst Events

The cloudburst events are categorized fundamentally into mini-cloudbursts and CB cloudbursts detailed as follows:

(a) *Cloudburst (CB)*

In India, rainfall is classified into three categories in terms of its intensity, defined by Deshpande et al. (2018). The classified ranges of rainfall are

>6.5 cm/day, >13 cm/day, >20 cm/day for heavy, very heavy, and extremely heavy, respectively, as per the Indian Meteorological Department (IMD). This rainfall intensity has further been classified according to the duration of the downpour.

(b) *CBa and CBb Cloudburst*

The cloudburst (CB) has been further classified into two categories as “CBa” and “CBb” in hours (Deshpande et al., 2018). Firstly, the CBa events predominantly occurring in the steep rugged terrain of the Himalayas which constitute a majority of events are associated with a heavy downpour. The impacts of CBa have been identified to trigger hazards such as flash floods and debris flow. Secondly, the CBb events have been categorized based on the rainfall rate of more than 10 cm/h. The CBb events have been observed to occur in many places of India, further discussed later.

(c) *Mini-cloudburst*

The term mini-cloudburst was first assigned by Ramage and Schroeder (1999). However, they were unable provide any significant quantitative analysis of this event. Another new classification of cloudburst event by Deshpande et al. (2018) is “mini-cloudburst” (MCB) which is recognized based on short-duration rainfall. The rainfall range of MCB is ≥ 5 cm in two consecutive hours (Deshpande et al., 2018). The mini-cloudburst events are more spread apart in India occurring in various regions including the Himalayas, Western Ghats, and central India. The occurrence of MCB is common during the monsoon period at the foothills of the Indian Himalayas, but the Western Ghats and central India experience the mini-cloudburst during the pre-monsoon season, particularly in June only. The majority of these events arise in the early morning in the Western Ghats and Himalayan region, but in the southern peninsula, it appears at night (Deshpande et al., 2018).

Past Study of Mini-cloudbursts

Some studies synthesized that the orographic process is not an only cause to an aggravation of these events. Therefore, the solar radiations and synoptic-scale might be primary factors to arise the mini-cloudbursts (Deshpande et al., 2018). In some regions, these events are generally associated with tropospheric cyclones and deep convective clouds in central India but are triggered due to orographic uplift in Himalayan regions. A study by Deshpande et al. (2018) shows the spatial distribution of mini-cloudburst and recorded rainfall where it varies from 7 cm to ≥ 22 cm in two consecutive hours. Such an amount of rainfall-runoff is sufficient to trigger flash floods at a localized level. Deshpande et al. (2018) depicted that the average occurrence of mini-cloudbursts is three per season in the Himalayan foothill and Western Ghats area but was rarely found in Rajasthan.

Figure 3 demonstrates the cloudburst events and associated rainfall at different stations geographically located at different regions of India, as illustrated in Table 1 (Deshpande et al., 2018). The blue bars in Fig. 3 indicate the rainfall of a particular

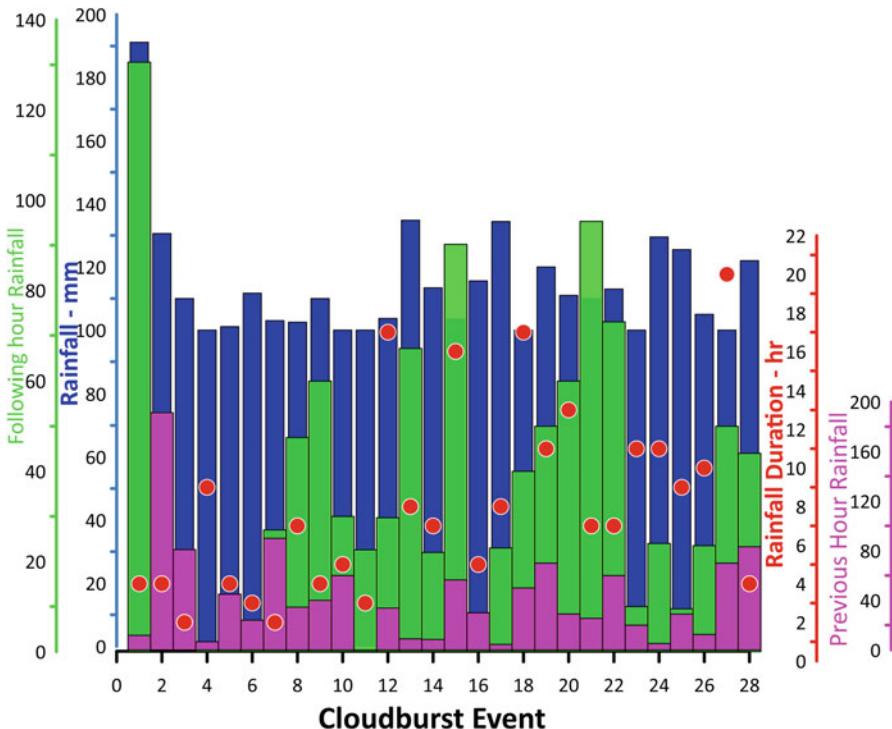

Fig. 3 The blue bars show the rainfall of a particular day of an event and its associated previous and following hour rainfall in magenta and green, respectively. The duration of the rainfall is highlighted in red dots

day of an event and its associated previous and following hour rainfall in magenta and green, respectively. The duration of the rainfall is highlighted in red dots. Based on this, data segregated the rainfall amount before and after an hour of the event and found that there are 22 cases where rainfall exceeded 10 mm in the previous 1 h (Deshpande et al., 2018). Table 1 illustrates details of historical mini-cloudburst events and corresponding recorded rainfall, while further including information on the previous and the following hour's rainfall of a particular day, when the cloudburst happened at specified locations.

Historical Cloudburst Events in IHR

We summarized the various cloudburst events between 1970–2020 in the various states and UTs of IHR in Table 2 and observed that the occurrence of these events is most frequent in the Uttarakhand region than in the other parts of the Himalayas. Taking into consideration the dominance of the cloudburst events in the Uttarakhand region, we analyzed the influence of elevation with respect to the occurrence of the

event for this regions as shown in Fig. 4. In Fig. 4, the graph shows the occurrence of cloudburst events (red dots) with respect to the elevation where 2000 m elevation is marked by the green line. It has been observed that the frequency of the cloudburst events is more between 1000 m to 2000 m elevation band of the Indian Himalayan region. This elevation band experiences low rainfall and high land surface temperature. The majority of the villages are located in these elevation bands. Therefore, this band is most vulnerable in terms of hazard and risk from cloudburst events (Mishra et al., 2022).

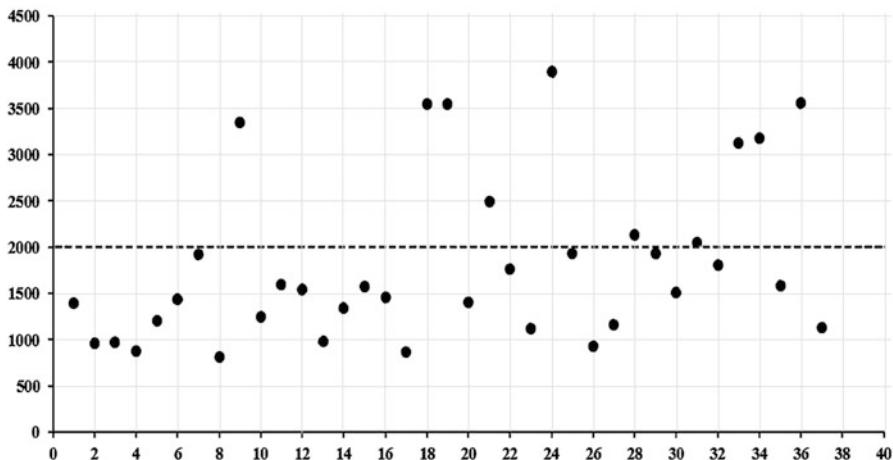

Fig. 4 Identification of prone elevation for cloudburst events for the Uttarakhand region in the Indian Himalayas. The red dots indicate the number of cloud burst events

Analytical Studies of Cloudburst Events in IHR

Remote Sensing and Geospatial Techniques

Satellite imagery has an indispensable role in monitoring, prediction, and assessment of natural disasters such as landslides, earthquakes, flash floods, and avalanches (Thayyen et al., 2020, 2021). While flash floods are commonly occurring in the Himalayan region for decades, their occurrence has been more frequent in the recent years due to extreme rainfall and cloudburst events in the mountainous region of India (Thakur, 2000; Thayyen et al., 2013, 2020; Kumar et al., 2018; Mishra et al., 2022). The assessment and prediction of these hydrologic extreme events are quite challenging due to ungauged basins and coarse resolution observed rainfall data (Mishra et al., 2022; Kumar et al., 2018). Satellite rainfall datasets are available at a relatively finer resolution like global precipitation measurement (GPM) and Tropical Rainfall Measuring Mission (TRMM). The GPM and TRMM datasets provide the rainfall data at every 210 min (<https://gpm.nasa.gov/missions/trmm>). These multi-temporal datasets are very useful in capturing the rainfall events that transform into cloudbursts and flash floods at the local level (Mishra et al., 2022).

A study by Mishra et al. (2022), the assessment of extreme rainfall and cloudburst events, has been done in Uttarakhand using geospatial data. They used multiple satellite datasets aided with field observations to identify the vulnerable administrative blocks in the Upper Ganga Basin from exposure to extreme rainfall and cloudburst events. The study focused on 57 extreme rainfall and cloudburst events. The entire analysis was carried out based on four factors that include elevation, precipitation zones, land surface temperature, and topographic controls from the perspective of cloudbursts. An SRTM DEM was used for elevation profiling of the entire region for the identification of the most vulnerable elevation band in terms of

the population from exposure to cloudburst events. By analyzing the profiles derived by SRTM DEM, it is observed that 66.6% of cloudbursts are going to occur between the 1000–2000 m elevation. Furthermore, these cloudburst events were also matched with heavy rainfalls based on TRMM/GPM (3-hour interval rainfall) for July and August during 2010–2020.

Based on the TRMM/GPM precipitation data, the events have been classified into two categories which are “standalone” and “prolonged” events. The 29 standalone events observed by Mishra et al. (2022) refer to cloudburst ranging from 1.65 mm/h to 65 mm/h, while 28 prolonged events termed as extreme rainfall lie between 10 to 154 mm/24 h. It has been noticed that the majority of the events take place in the low rainfall region based on the TRMM data (Mishra et al., 2022). In their study, the MODIS-land surface temperature was also accounted to identify the favorable warm zone that varies from 18 °C to 28 °C to facilitate the cloudburst events. This temperature band comes under low elevation and high-temperature zone of topoclimate regimes of Uttarakhand (Yadav et al., 2020). This work concludes that the 1 million population spread over these regimes is highly vulnerable from exposure to extreme rainfall and cloudburst events.

Simulation of Cloudburst Events

The orographic lifting carries an unstable moisture content that releases the convective available potential energy to arise the cloudburst also called *rain gust*. Hence, numerical simulation is necessary to understand the interactions of clouds and orographic dynamics for building a conceptual model of cloudbursts. A study by Das et al. (2006), the mesoscale MM5 numerical model, was used at 9 km and 3 km domains to characterize the cloudburst events. This event occurred in Shillelagh village of Himachal Pradesh on 16 July 2003.

A study by Das et al. (2006), the numerical weather prediction (NWP) model, was used as a basis for deriving the conceptual model for cloudburst simulation using vertical shear, vertical motion, and its moisture distribution. This model elucidates the three stage life span of cloudburst events. The first stage showed the separation of two convective cells and moves away from each other which lead to isolated heavy rainfall. In the second stage, the amalgamation of two convective cells takes place because of intense wind shear and vertical motion. During this stage, a rain gust occurs. The third stage depicts the formation of one single cell from two convective cells. In this stage, the triggering process of cloudburst comes to end. Furthermore, the hydrometeors of the cloudburst and its microphysical properties are extracted by TRMM data and simulation, respectively.

In a nutshell, these numerical models may help to categorize the stages of cloudburst and their rainfall intensity. Another study by Sravana Kumar et al. (2012) simulated the cloudburst over Leh (5 August 2010) using Weather Research and forecasting (WRF) model for the localized mesoscale event by determining various key parameters. Romatschke and Houze (2011) investigated some mesoscale parameters contributing to precipitation based on TRMM data. Kumar et al. (2014) used a coupled land surface and atmospheric model to simulate a storm scenario resulting in a flash flood. Shrestha et al. (2015) employed the regional weather

forecast model Consortium of Small-scale Modelling (COSMO) for the Himalayan foothills to investigate an extreme rainfall event.

Hydrometeorological Approach

The hydrometeorological data has a significant role in understanding the cloudburst events, but due to scarcity of stations, the data is not regularly available. A recent study by Kumar et al. (2018) explained the cloudburst events using available hydrometeorological data and source of moisture content for cloudburst in the IHR. The metrological forcing has been analyzed including air temperature and pressure. This work also comprises the hydrometeorological data in terms of its variability and distribution during the cloudburst. To know the vapor content of these cloudbursts, the pathways of vapor have been traced through wind trajectories using a Hybrid Single-Particle Lagrangian Integrated Trajectory (HYSPLIT) model (Draxler and Rolph; Yerramilli et al., 2012). The tracing of these pathways is only for selected cloudbursts during pre-monsoon, post-monsoon, and the monsoon season. By analyzing all these factors, the windward side of the Himalayas is favorable to cloudburst, while the leeward side is moisture deficit (Kumar et al., 2018). The dominant moisture content during monsoon comes from the Arabian sea, but local moisture primarily sources during pre- and post-monsoon for these cloudbursts. These moisture-laden winds merge with local moisture and land in a low-pressure region of the Himalayas which turns into rain gust or cloudbursts. A similar work was carried by Srivastava and Bhardwaj (2014), Shukla et al. (2013), and Sundriyal et al. (2015).

Present State of Activities on Account of Cloudbursts

Several cloudburst events in the Himalayan region are unreported (Mishra et al., 2022; Thayyen et al., 2013). Nevertheless, the inventory of 82 cloudburst events in Table 2 provides significant information for developing strategies for cloudburst management and planning counteractive measures, particularly in the IHR. This inventory and past studies will also help in developing adaptive intervention against disaster risk reduction in the IHR.

Presently, it is challenging to forecast cloudburst events. However, a dense network of weather stations particularly in the elevation band of 1000–2000 m would prove to be a highly significant resource for the modeling and forecasting of cloudburst events. Besides weather stations, advanced early warning systems based on Doppler radar stat can be deployed at cloudburst hazard zones of sever intensity in IHR. A network of such stations is also highly sought to record precisely the extreme rainfall events which transforms into cloudbursts and their characteristics to improve our understanding of this phenomenon.

A useful approach in cloudburst management is being adopted in the city of Copenhagen, where municipal department has organized a cloudburst masterplan coupled with advanced structure implementations (Baykal, 2012). The plan is expected to be fully implementable in about 30 years time. The plan is envisioned with a view to cope with the effects of climate change and focuses at fixing

acceptable limits of flooding in the streets (tentatively fixed at 10 cm). The plan aims to decouple 30 to 40 percent of the excess storm water from the combined sewer system to level out the expected 40 percent excess rainfall due to climate change over a 100 year period. The plan incorporates both concretization of ideas and implementation of specially designed structures such as creation of strategic canals and the greening of Copenhagen. The report by Baykal (2012) indicates that Copenhagen represents the way forward in long-term planning for some of the aberrations that might be caused by climate change. An inbuilt mechanism to combat a disaster is the best solution, provided it delivers.

According to the Uttarakhand State Disaster Management Authority, the different aspects such as geology, geomorphology, and climatology should be accounted for in developing a forecasting model for cloudburst events (<http://usdma.uk.gov.in/cloudburst-15.aspx>). However, simultaneously, it is imperative that residents of the cloudburst vulnerable zones be aware of such extreme precipitation events and associated disasters (<http://usdma.uk.gov.in/cloudburst-15.aspx>). Subsequently, educational and awareness programs are also highly sought and need to be organized periodically.

Conclusion

The Indian Himalayas have witnessed historically frequent occurring of cloudburst events where Uttarakhand has been severely affected by these events when compared with the other states and UTs of the Indian Himalayas. The UT of Jammu and Kashmir and Ladakh were the second most vulnerable regions that were often hit by cloudbursts. Predominantly, in the Himalayan region, cloudburst events are falling in the low rainfall region where the elevation and land surface temperature are low and high, respectively. The occurrence of CB events per unit area is very high in Uttarakhand as compared to other regions in the Indian Himalayas. The recent cloudburst events have been more severe and had relatively more community impact. These events were known to lead to severe fatalities, loss of livelihood, economic loss, and property damage.

Due to the complex mechanism of cloudbursts and the constraints of data appropriately and availability, comprehensive studies on cloudbursts are yet limited owing. The data-related issues are primarily associated with the spatial resolution of the satellite data (best resolution data is available at 5 km, CHRIPS) required for such events that are focused on a much smaller region (sometimes <1 km radius) than that could be analyzed by the present spatial resolution of the satellite data. The mini-cloudburst (CBb) has been diagnosed based on the statistical characteristics of rainfall 10 mm/h. The frequency of mini-cloud has increased in many parts of India. The CBA cloudbursts which are dominant in the IHR are observed to be more severe than the others and are difficult to model.

Several studies indicate that the present capabilities of the sensor network are insufficient in providing the required volume of timely data for characterization and modeling of cloudburst events, particularly due to their inherent complex

mechanism. Subsequently, it has been challenging to understand the triggering phenomena of cloudburst and its post-event impact. Understandably, studies of cloudbursts are significant from multiple perspectives, particularly related to their prediction and pre-/post-event management and mitigation activities. Even though a certain depth of understanding has been achieved on the same, concrete actions in terms of policies, planning and management by national and global organizations are yet limited, and more thrust is envisaged on the same.

Abstract

Epidemic source tracing is crucial in epidemiology. Historically, from the 1832 Paris and the 1854 London cholera epidemics to the recent Wuhan COVID-19 epidemic, source tracing followed the strategy of a post facto analysis of infections and mortalities. On January 12, 2010, a 7.0 magnitude earthquake ravaged Haiti resulting in a cholera epidemic causing 8646 deaths. Cholera being a water-borne disease, it became imperative to identify the source of contamination.

Following the historical practice, an exhaustive analysis of the 8646 cholera deaths, lasting almost a year, was carried out. It identified an earthquake damaged sewage drain, emptying into the Artibonite River, the regional source of water, as the source of the Epidemic. An analysis of the damaged waterways, just after the earthquake, could have been carried out with the help of GIS (Geographic Information Systems including Satellite Data). This could have identified the contamination source before the outbreak of the Epidemic. GIS has become a sophisticated mature field, accessible to domain experts, e.g., ESRI, a private company (among others), specializes in GIS.

In the 1970s, space technology confirmed its impact on public health by pointing out Ozone Layer depletion causing severe UV-related medical

malignancies. This led to a worldwide restriction on CFC. Taking this as an example of space technology benefitting Disaster Medicine, in 2016, we proposed to investigate the possibility of detecting the damaged sewer drain by comparing before and after earthquake images, available from, open source, NASA/Landsat. If successful, the contamination source could have been detected before 8646 cholera deaths occurred. This involved Satellite Data File Acquisition, Image Extraction from Data Files, and Image Noise Management to identify relevant features. This required dedicated hardware/software environment generally available from proprietary commercial sources. Such a proprietary environment, however, does not allow a detailed examination or flexibility in the underlying processing and is not suitable for a research study. Accordingly, we restricted ourselves to open sources, e.g., NASA/GSFC/USGS. This allowed us to do an ab initio, first principles, Image Processing as outlined in this chapter. Both Landsat 5 & 7 images were available. An image taken after the earthquake was analyzed to test if the relevant waterways could be detected. This image, based on 1990s technology, did not offer adequate spatiotemporal resolution to detect relevant waterways, e.g., the damaged sewer drain. In this case, 1990s Space Technology, due to its limitations, did not, thus, offer the expected benefit to Disaster Medicine by identifying the source of contamination before 8646 cholera deaths occurred. Since 1990s, Space Technology, however, has advanced considerably and the first principles' image analysis, presented in this chapter, is superseded by high-resolution images now available from various sources. This chapter aims to explore the potential of space technologies, e.g., satellite imaging, GIS, etc. to offer potential benefits to Disaster Medicine. A brief discussion of the analysis done for this chapter and some of the emerging space technologies with potential relevance to Disaster Medicine will be presented.

Keywords

Disaster Medicine · Space technology · Cholera epidemic

Introduction

On January 12, 2010, a Richter 7.0 earthquake struck Haiti. The ensuing damage and casualties from this earthquake have been extensively studied (2010 Haiti cholera outbreak, 2012; Centers for Disease Control and Prevention, 2010; Walton & Ivers, 2011). An estimated 230,000 people were killed. Another 300,000 were injured. In addition, 711,442 cases of cholera with 400,103 hospitalizations and 8646 deaths were reported. Cholera being a water-borne disease, it became imperative to identify the source of contamination. To trace the source of contamination, the sites of 8646 cholera deaths were analyzed. It is perhaps instructive to recall that this method of analyzing progressive causalities, to trace the source of contamination, follows a history of almost 200 years, starting with the 1832 cholera outbreak in Paris (Rapport sur la marche, 2012) and the “1854 Broad Street Cholera Outbreak” (1854 Broad

Fig. 1 Cholera deaths

Fig. 2 Cholera reporting centers

Street Cholera, 2009). In both cases, cholera deaths were plotted on street maps, Fig. 1, to identify the source of contamination.

Almost along the same lines and extending to the genetic profile, Piarroux (Piarroux et al., 2011) and Frerichs (Frerichs et al., 2012) carried out a comprehensive analysis of cholera deaths. A network of stations was established to collect data on cholera deaths over almost 2 months (Fig. 2).

By analyzing the time evolution of the clusters and extensive DNA profiling, the source of the cholera outbreak was traced to Meille village (Mirebalais region), Fig. 3, where a stream was flowing into the Artibonite River, the main source of

Fig. 3 Cholera clusters

drinking water. The Earthquake damaged a “Sanitation Drain” and polluted the stream that was a tributary to the Artibonite River.

The historical paradigm for epidemiology is thus:

1. Data collection (when and where infections/mortalities occurred).
2. Pattern recognition, i.e., source identification by data clusters.

This paradigm has also become the “Gold Standard” of clinical trials. Data collected from double blind, random samples is subjected to very sophisticated statistical analysis to detect patterns.

In its simplest form, it may just be to prove or disprove the null hypothesis that a drug/medical procedure is effective or not.

Medical disasters often follow environmental events, e.g., floods, forest fires, earthquakes, etc.

It will be most desirable if it is possible to monitor “precursor environmental parameter” that could predict a medical event. Preventive measures could then be taken before infections/mortalities occurred.

This will be a paradigm shift from the classical (post facto) data/pattern paradigm mentioned above.

The new paradigm.

1. Monitor medically relevant parameters.
2. Initiate preventive measures before medical incidents occur.

This, whenever possible, will be most desirable for Disaster Medicine.

Space technology has advanced enough to monitor, 24/7, many environmental parameters of medical relevance. A most notable, historical, example of this is the satellite-based “Ozone Layer Depletion” study (Ozone layer depletion, 2004).

In brief:

1969 Paul Crutzen and later.

1974 Mario Molina and F. Sherwood Rowland.

Identified CFCs as harmful to the ozone layer. They were awarded the Nobel Prize in 1995.

In the 1980s, NASA/NOAA started atmospheric monitoring but did not discover ozone depletion.

In 1985, Joseph Farman, Jonathan D. Shanklin, and Brian G. Gardiner proved the ozone layer depletion.

In 1987, NASA/NOAA claimed to have had data on “Ozone Layer Depletion” but detected it only after 2 years of intense, advanced data processing.

Ozone layer data was immersed in the “noise” of the general satellite data stream. It required specific (noise suppression) processing of satellite data to extract ozone sensor data. This yielded an image of the ozone layer and its connection to CFC (ozone layer and CFC). It led to a worldwide ban of CFC, preventing outbreaks of UV-induced melanoma, cataract, etc. This established the relevance of space technology to Disaster Medicine.

In January 2010, an earthquake hit Haiti. About 10 months later, a cholera epidemic caused 8646 deaths. Was it possible to study Earthquake-induced environmental changes and predict the possibility of a cholera outbreak? In this chapter, an attempt was made to “Identify the Source of the Haiti 2010 Cholera Outbreak” by comparing “before and after, Satellite images” of the earthquake zone. If successful, this could have identified contamination source before the cholera outbreak claimed 8646 deaths.

Method

The cholera outbreak was due to the contamination of the Artibonite River by a sewage drain in Meille village (Haiti, Mirebalais region). Figure 4 (Maps of the Mirebalais region, can be obtained by authorized users from USGS or from public domain: <https://www.google.com/maps/@18.8368863,-72.1089578,15z?entry=tlu>) shows the general course of the Artibonite river.

Waterways and tributaries in the Mirebalais region are of primary interest. These waterways can be highlighted, Fig. 5, by simple “photo-enhancements” of Fig. 4 (Google App <https://www.google.com/maps/@18.8368863,-72.1089578,15z?entry=tlu>).

Fig. 4 Mirebalais source region

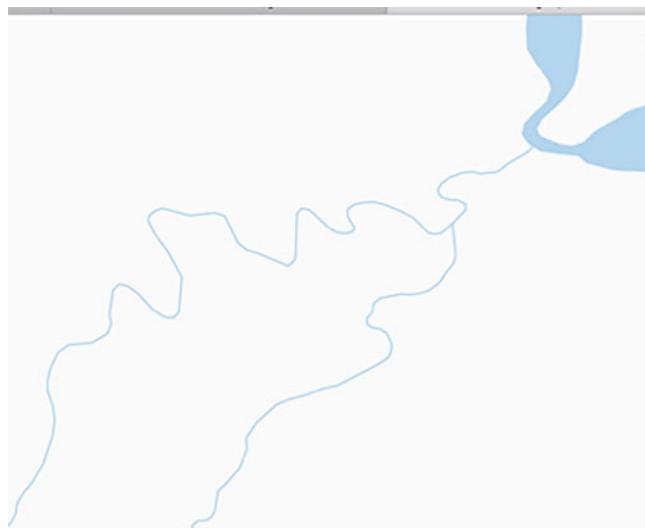

Fig. 5 Waterways in source region

In this chapter, it was attempted to identify the waterways and minor tributaries in the “before and after” satellite images and detect any significant realignments that could have caused sewage drain into a tributary of the Artibonite river. Satellite images are available from a variety of sources. ESA/Copernicus/Sentinel. ESA-GEO-EYE

(ESA-GEO-EYE) is a commercial source. For this chapter, images were acquired from the public domain NASA/LANDSAT (LANDSAT-7 Images), associated with NASA/Goddard Space Flight Center (GSFC) (US Geological Survey (USGS)).

NASA/Landsat is a series of civilian earth observation satellites. For this chapter, NASA/LANDSAT5&7 were available. LANDSAT7 was launched in 1999, and it covered 2010 earthquake period. Unfortunately, in 2003, LANDSAT7 developed an SLC (Scan Line Correction) malfunction which complicated data processing thereby, perhaps, impacting the ultimate result. It is important to remember that the Earth, the Sun, and the Satellite are in constant motion. As a result, images taken from a satellite at two different times (as needed for this study) may have variations due to relative positions, solar illumination, cloud cover, etc. Only satellites in special orbits can offer some uniformity. LANDSAT satellites are in “Sun Synchronous Orbits” such that the satellites are in fixed positions relative to the Sun. LANDSAT-7 observes the earth in different spectral bands (Table 1):

These bands generate data as a byte-stream (values between 0 and 256). Panchromatic data used here is a 3-byte stream; 1 byte for each red, blue, and green color. A typical image, e.g., defined by file header:

“LE07_L1TP_008047_20160216_20161015_01_T1_sr_band1” is a 3d-matrix of (7091×8121) elements with 3 bytes at each element. This bit stream of $(7091 \times 8121 \times 3)$ values is downloaded as “grey-strip” forming an image as .tiff (Tagged Image File Format) file, Fig. 6a.

The .tiff image itself, being just a very large data file, is not, by itself, suitable for identifying terrain features, e.g., river tributaries, relevant to this study and must be converted into other format(s) for further processing.

There are commercial resources available that can employ thematic enhancement to suppress noise and accent-desired features. Such thematic enhancements, perhaps aided by AI techniques, may lead to pattern-driven-recognition, e.g., enhancing waterways, Fig. 6b. An aggressive noise management and feature enhancement may also lead to spurious artifacts, e.g., false positive. Speckle in optical imaging

Table 1 Landsat-7

Band number	Spectrum	Wavelength range (μm)	Resolution
1	Visible	0.45–2	30 m
2	Visible	0.52–0.60	30 m
3	Visible	0.63–0.69	30 m
4	Near infrared	0.77–0.90	30 m
5	Near infrared	1.55–1.75	30 m
6	Thermal	10.40–12.50	60 m
7	Mid infrared	2.08–2.35	30 m
8	Panchromatic	0.520–0.90	15 m

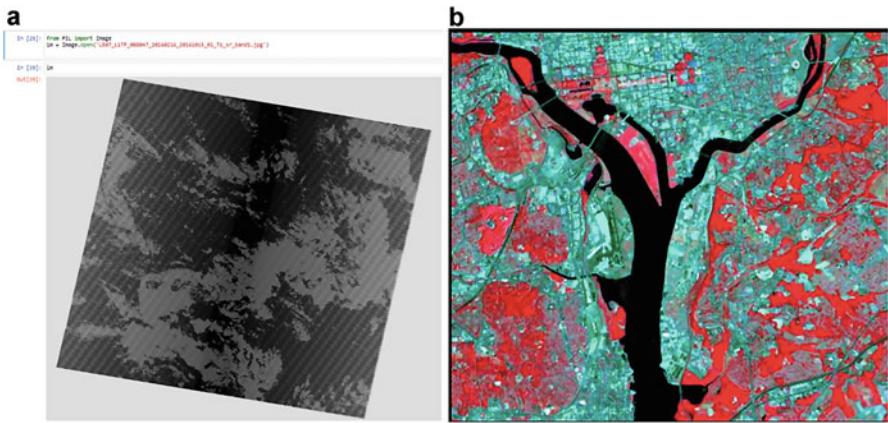

Fig. 6 (a) Typical Landsat .tiff image; (b) false color, simulated 15 m IR image, Washington, DC. Landsat 7

is a common occurrence, and digital filters can eliminate it. On the other hand, in Speckle Interferometry filters, to preserve and even enhance Speckle are desirable. This is an example of user-selected, i.e., pattern-driven, image processing, and the final result may depend on the user's choice of filters, etc.

In this chapter, we restricted the analysis to raw satellite data processing and controlled noise management.

Traditionally it involved a lot of data processing requiring special hardware/software environment. Since LANDSAT7, however, current technology has advanced considerably and high resolution, multispectral satellite images are now routinely available without having to go through the cumbersome format conversion, data processing, noise filtering, etc. employed in this chapter.

Below is a brief outline of such techniques used in this study.

Image formats:

GIF-Graphics Interchange Format. Historic format for simple web graphics with limited colors, always reduced to 8 bytes (256) colors. GIF files are small and easy to work with.

tiff-Tagged Image File Format. “Bitmap of Image Strips” containing a vast amount of information. .tiff files are very big (around 500 MB) as they are “lossless,” i.e., no information is lost due to compression. Satellite images are downloaded in this format and mostly must be converted into more manageable formats.

.png-Portable Network Graphics is the format for small files, i.e., smaller than .tiff, that preserves its color quality in graphic image files like charts, logos, etc. Note that .png does not support CYMK format as required by some publishers.

.jpeg-Joint Photographic Experts Group, also jpg, is the format for online photos. It supports a full spectrum of colors, and almost all devices, e.g., smartphone, selfies, and programs, can open and save to the JPEG format, making it the most universal of the four. JPEG files are ideal when you want to keep the file size

Fig. 7 Haiti, Mirebalais region (Frerichs et al., 2012) .jpeg image

down and do not mind giving up a little quality to create a very small file. JPEG quality drops when images are edited and saved.

A typical sequence of steps could be:

1. Select the appropriate location and before-and-after times for comparison. Download the corresponding large LANDSAT-7 .tiff files.
2. Convert .tiff to .png, images using USGS/GIS software to preserve color quality and storage as files much smaller than .tiff files.
3. Convert png to jpeg for visual comparison of areas of interest.

Figure 7 is an annotated presentation of a .jpeg file of the area of interest.

This could help visually recognize the river and its tributaries. Comparison of “before and after” images could help recognize the realignment of tributaries and thus identify the sewage drain as the source of cholera epidemic. Visual comparison of such images could not identify details of the tributaries due to noise, limited visual acuity, and resolution.

Image processing:

A large selection of digital image processing techniques to extract details from noisy images is available from commercial sources and some open sources, e.g., USGS. To use such techniques, an image must be first converted to a numerical 2d-file, e.g., Excel. The next step should thus be:

Convert selected .tiff files to Excel for numerical analysis.

However, .tiff files are very large and the corresponding Excel files become too large to process by standard techniques. On the other hand, .jpeg files are much

Fig. 8 tiff to .jpeg to .xlsx conversion sample

smaller and preserve color quality and can be converted to manageable Excel “color” files of Red, Blue, and Green. Conversion of .jpeg to an Excel file requires appropriate software, e.g., the Python program illustrated below:

LANDSAT-7 file “LE07_L1TP_008047_20160216_20161015_01_T1_sr_band1” has values stored in the matrix ($7091 \times 8121 \times 3$) each value is within (0, 255).

The following, including Python Imaging Library (PIL), outlines a possible process to convert the image array into the desired 2d shape.

```
Imarray = np.array(im)
K = imarray.shape
imarray = imarray.transpose(2,0,1).reshape(K[0]*K[2],K[1])
```

The following command is used to save the array into .xlsx format.

```
imarray.tofile('C:/Users/....result_files/result_1/test_sdp_3.xlsx', sep=",")
```

The 2d matrix is thus an Excel file with each element containing 3 bytes, one each for Red, Blue, and Green color. This .xlsx file can now be numerically manipulated to reduce noise and possibly recognize relevant features.

Figure 8 illustrates a very small part of the numerical data for each pixel in red, blue, and green color. As there are eight bands, a set of eight such files is a full numerical version of LANDSAT-7 images and requires various operations.

The goal is to take numerical versions of two time-lapsed images of one area before and after the earthquake, and numerically detect any changes between them. Thus, images $I(1)$ and $I(2)$ are taken at times $t(1)$ and $t(2)$ before and after a “disaster,” e.g., earthquake, flood, industrial accident, etc. In principle:

$$I(1) - I(2) \quad (1)$$

should highlight some features relevant to public health.

Images $I(1)$ and $I(2)$ as obtained from Landsat are numbers on a geometrical grid (x,y) . At each point x and y , there are eight spectral band values; thus, Image (1), of time 1, has spectral band s intensity at point x,y :

$$I(1, x, y, s) \text{ where } (s = 1, 2, 3, 8,) \quad (2)$$

Similarly, the image at time (2) is:

$$I(2, x, y, s) \text{ where } (s = 1, 2, 3, 8,) \quad (3)$$

In principle,

$$I(1, x, y, s) - I(2, x, y, s) = D \quad (4)$$

is a set of eight images (one for each spectral band) and should show any anomaly due to the event. In practice, however, two time-lapsed images generally need to be expressed on a “normalized” grid to compensate for:

x translation a

y translation b

x “magnification” p

y “magnification” q

Grid rotation r

In principle, this can be folded into a “Normalization” function:

$$N(x, y, a, b, p, q, r)$$

Thus, (4) becomes:

$$I(1, x, y, s) - I(2, N(x, y, a, b, p, q, r), s) = D \quad (5)$$

Recall that (5) is a set of eight images, one for each spectral band. To solve Eq. (5), special procedures to handle multidimensional very large data files of satellite images are required.

Access to such expertise for these operations was essential. Such facilities and expertise are available to any account holder at NASA, GLOVIS, USGS, etc., or private sources such as ESRI (Environmental Systems Research Institute (ESRI)).

In principle, D, Eq. (5) is the change due to earthquake, e.g., realignment of a tributary. It does, however, include the ever-present Random Noise R in each image. Thus Eq. (5) with random noise R should be:

$$[I(1, x, y, s) + R(1)] - [I(2, N(x, y, a, b, p, q, r), s)] + R(2) = D \quad (6)$$

Random noise is not canceled by subtracting two “noisy” images. As a matter of fact, the noise is additive, i.e., subtracting two noisy images will yield a noisier image, thus:

$$D \Rightarrow D + R(1) + R(2) \quad (7)$$

The noise $R(1) + R(2)$ sets a detection threshold for the size of any earthquake-induced alteration, e.g., realignment of drains, etc. Any earthquake-induced change not significantly above the noise threshold will thus not be seen.

Results

Figure 9 is an illustration of a typical pattern obtained by comparing two images, as described in Eq. 7 above.

This pattern is dominated by noise, and no landmark can be detected without noise management. Image noise management/suppression/filtering has become a major subfield of Digital Image Processing, Gonzalez (Gonzalez, 2008), Solomon (Solomon & Breckon, 2010). Two common approaches to Noise filtering are:

1. Domain filtering (D), e.g., Fourier Transform, Histogram Correction, Photogrammetric Gamma Adjustment, etc.
2. Convolution Kernel Filtering in Spatial Domain (S, Spatial Domain)

One may use D or S, OR both D and S. Of course, D and S do not commute, i.e., $D \times S$ is NOT EQUAL to $S \times D$.

Both D and S can be chosen in multiple of ways, e.g., D can filter high, low, and mid frequency, or even a particular band. Similarly, S can operate on a kernel of one or many pixels. There is thus a wide choice of D and S filters. Further, combination of D and S gives even a much wider choice. If D has n possible values and S has m possible values and 1 for no filter, then:

$(n + m + 1)$ possible filters for single pass.

Often multiple passes of filters are used. For a $2 \times$ pass filter, one gets:

$(n + m + 2mn)$ possible filters.

Fig. 10 Selective noise suppression for time lapse comparison

For a modest double pass of $m = 2$ and $n = 2$, one gets 12 filtered images. Which of the 12 filtered images is accepted is purely a matter of “User Driven” pattern recognition, i.e., what the user wants to see.

One can thus train a system to see if a certain pattern appears. This becomes the basis of emerging AI-based pattern recognition, which was beyond the scope of this chapter.

By using different noise filters, a faint, tributary could be seen in Fig. 10. This feature was sensitive to the choice of noise filters. With a sensor resolution limited to 15–20 m, the noise content in the original tiff file was too high to allow the detection of 0.5–1.0 m features. It was, thus, not possible to identify relevant landmarks.

Comparing two such files showed mostly noise, and no distinct landmark realignment (sewage drain) could be identified.

An AI-based pattern recognition system, e.g., Convolutional Neural Network (CNN), could perhaps be trained to detect relevant features with greater sensitivity if a proper set of “training” images is available. It is, however, still not clear if an AI system can reach sub-millipixel resolution, i.e., 50 cm. resolution in a 15 m pixel image as required for this study.

Conclusion

Cholera epidemic in Haiti, caused by the 2010 earthquake, resulted in 8646 deaths. Cholera being a water-borne disease, its contamination source, a damaged sewage drain, was identified by the customary post facto analysis of the 8646 deaths. Inspired by the success of the satellite-based monitoring of the ozone layer in 1970s and thereby predicting UV-related health hazards, this chapter attempted to detect the contamination source by analyzing LANDSAT satellite images before and after the earthquake. If successful, it would have identified the contamination source

before the onset of the epidemic. Limitations of spatirospectral resolution of onboard sensors and standard numerical image processing could not identify the contamination source.

Since LANDSAT 7, significant advances in space technology and digital image processing have occurred. Advanced satellites, e.g., LANDSAT9, the Hubble Telescope and its successor JWST (James Webb Space Telescope) could detect biomolecules (CH_4 , NH_3 , H_2O , etc.) in galaxies light years away. With such advances, it might be possible to detect the migration of bats and thus perhaps COVID-19 virus. Numerous LEO (Low Earth Orbit) satellites could possibly correlate human population and animal migration for possible zoonotic transfer. Both NASA and ESA have started new space-based initiatives to aid the COVID-19 pandemic (ESA COVID-19). Even the ubiquitous GPS signal consists of information about Earth's hydrologic cycle. GPS signal can distinguish whether the surface is wet or dry, how much water is contained in the soil and vegetation, and how much snow is on the ground (Chew, 2022). Similarly, space-borne monitoring of methane (Monitoring Methane Emissions), the second most-abundant anthropogenic greenhouse gas, is being pursued. Further, geologic high-resolution terrain profiles, till 2012 classified secret, are now available from SAR (Synthetic Aperture Radar) resources, Butterworth, Quill (Butterworth, Quill). Identification of terrestrial chemicals of medical relevance could be aided by Hyper-spectral Imaging (Hyperspectral Imaging). There is even an attempt to analyze information from Mars (Mars Mission) to advance medical knowledge.

Along with advances in Space Technology, very significant advances have been made in Satellite and Medical Image Processing. LeCun (LeCun et al., 2015) and Habibi (Aghdam, 2017) successfully used Convolutional Neural Networks (CNN) in Medical Radiology. Paras (Lakhani & Sundaram, 2017) achieved automated tubercular tumor detection.

Based on such advanced Space and AI technologies, one could design a Satellite Data Center that receives medically relevant environmental data. This data stream can be continuously and autonomously monitored to detect medically relevant anomalies and generate appropriate alerts.

Abstract

The Himalayan region is a seismically active zone and has witnessed the massive loss of properties and lives due to the collapse of infrastructure and lack of preparedness. Many studies focus on the susceptibility analysis; however, in this chapter, we have considered the dynamic nature of the earthquake hazard and factors affecting the resilience at the household level. This chapter considers the aspects of environmental, economic, social, and physical parameters for resilience analysis. An amalgamated indicator-based framework has been developed including the level of exposure, coping capacity, and the level of resilience to assess the household vulnerability to the earthquake in the study area using indicators and subindicators. The outcome of the study establishes the risk of residential, commercial, and mixed-use buildings and their association with wider

socioeconomic consequences of a major earthquake event. Lack of resource diversification, gaps in the implementation of building codes, and lack of awareness have put households at high risk. Further, the chapter highlights large migration from surrounding villages as a significant factor affecting the overall resilience of the community. Since this framework adopts vulnerability as the primary criteria to the dimensions with a bottom-up approach for analyzing the resilience of the household, it can be applied to other hazards and locations too at microlivelvel planning for disaster risk reduction.

Vulnerability · Resilience · Household · Earthquake · Geospatial technology

Introduction

Earthquakes may strike for a few seconds or minutes but have a tremendous potential to cause mass destruction of properties and loss of lives. The primary cause behind this level of destruction is the failure of physical infrastructure (Meena et al., 2013). Apart from this, rapid population growth, unplanned urbanization, use of poor construction materials, and lack of awareness about their surroundings and building codes make people susceptible to earthquake impacts. Earthquakes are difficult to predict, and their ability to strike unanticipated makes them the most damaging event. With the subduction of continental plates or due to slipping of faults against one another, massive energy is released which travels through the crust in the form of seismic waves causing sudden shaking of the ground (Gaur, 1994). The continuous subduction of the Indian plate beneath the Eurasian plate has resulted in the upliftment of the Himalayas along the northern frontier region. This ongoing convergence of the two plates builds stress in the region making it highly prone to earthquakes (Rautela et al., 2007; Jayangondaperumal et al., 2017).

According to the Earthquake Hazard Zonation Map of the Bureau of Indian Standards (BIS), 56% of the Indian geographical area is prone to moderate to severe earthquakes (NDMA, 2019). BIS in 2017 has demarcated the whole parts of northern and north-eastern India and partially in Himalayan regions of Uttarakhand, Himachal Pradesh, Jammu, and Kashmir, Leh, and the western parts of India Rann of Kutch (Gujarat), parts of North Bihar and islands of Andaman and Nicobar into zone V meaning, seismically highly active zone (PIB, 2017). Several severe to moderate earthquakes of different magnitudes have occurred in the Himalayan region (Assam (1897, 8.3 M) and (1947, 7.3 M), Assam-Tibet (1950, 8.6 M), Bihar (1988, 6.9 M), Uttarkashi (1991, 6.8 M), Killari (1993, 6.2 M), Chamoli (1999, 6.8 M), Bhuj (2001, 7.7 M), Kashmir (2005, 7.6 M), Nepal (2015, 7.8 M), and Manipur (2016, 6.7 M)) (NDMA, 2019) causing around 40,000 fatalities due to collapse of buildings. Key observations on the failure of infrastructure in the earthquake-affected areas are inappropriate implementation of earthquake resistance in buildings, lack of awareness of the consequence of earthquakes among people, lack of professional

environment in the construction field, and inadequate system to check the implementation of BIS guidelines or to penalize its violation (NDMA, 2019). The vulnerability of the built-up environment of the country calls for quick intervention in terms of timely investment in seismic resilience building (Rautela et al., 2020). In the disaster management cycle, the vulnerability is the “characteristics and circumstances that make the system susceptible to the damaging effects” (UNISDR, 2009), “the measure of hazard and its implication on the physical, economical, and social components that affect the ability of the system to cope (ODPM, 2013; UNISDR, 2017; Yusmah et al., 2020). Proag (2014) discussed vulnerability as “risk combined with the level of social and economic liability, and the ability to cope with the resulting event,” or “the degree to which a system, or part of a system, may react adversely during the occurrence of a hazardous event.” Resilience is the “ability of the exposed system to resist, absorb, and accommodate to recover from the effects of a hazard in a timely event with efficient manner, including through the preservation and restoration of its essential basic structures and functions (UNISDR, 2009; Proag, 2014; Yusmah et al., 2020),” or “ability of a system to handle commotions while maintaining the efficiency in social, economic, physical and environmental aspects” (Combaz, 2015; Yusmah et al., 2020). The concept of resilience is an amalgamation of biophysical and socioecological attributes of a specific area (Bera et al., 2020). Past literature makes it clear that infrastructure failure is the major contributor to massive death rates during seismic events and causes a delay in emergency response (Cobum et al., 1992; Osaki & Minowa, 2001). Detailed seismic vulnerability assessment of infrastructure needs technical skills and is an expensive and time-consuming process. Rapid population growth, unplanned urbanization, migration, poor construction, and lack of awareness about the hazard amplify the seismic risk of a particular place. Reservoir-induced seismicity and landslides are also responsible for triggering a seismic event (Berg et al., 1969).

Considering the dynamic nature of the earthquake, studying the vulnerability of infrastructure will not be sufficient to handle it and a comprehensive approach is needed to assess the resilience of a particular region, keeping in mind the abovementioned factor, which also can act as a modifier (Peek-Asa et al., 2003). Attempts have been made to establish a link between vulnerability and resilience, marking them overlapping as well as discrete concepts (Kafle, 2012). Adger (2000) defines vulnerability as the state of susceptibility to destruction from hazards linked with the socioecological change and from the inability to adapt (Béné et al., 2012), which links vulnerability and resilience as “responding and implication” for humans and nature. In another attempt, “the buildup or wearing down of the attributes of socio-ecological resilience influence vulnerability, distinct events expose underlying vulnerability and push systems into new domains where resilience may be reduced,” leads to a circular explanation: “a system lacks resilience because of its vulnerability; it’s vulnerable because it lacks resilience.” Hence, establish a loose antonym between resilience and vulnerability (Adger, 2000; Béné et al., 2012). The main aim of the study is to assess the level of resilience in the earthquake-prone region among the household. To achieve these objectives and to develop a methodology, we treat resilience as an inbuilt capability of the community or individual to resist,

overcome, and recuperate efficiently from the disturbance caused by an earthquake in each place (Brigit & Sophie, 2008; Bera et al., 2020).

Study Area

The Kathgodam city lies in the foothills of lower Siwalik on the bank of the Gaula River and falls in Bhabhar plain. It is a part of the Haldwani-Kathgodam township and falls on the southern side of Nainital district, Uttarakhand State, India (Negi, 2018). The study area is situated in the proximity of the active Himalayan Frontal Thrust (HFT) and Main Boundary Thrust (MBT) fault line (Rautela & Pande, 2005). The geology of the area comprises an alternate bed of sandstone and clay shale (Valdiya, 1992).

The temperature in the study area is warm and temperate cold; during summer, the temperature ranges from 40 °C to 45 °C and in winter goes down to 4 °C to 1 °C. The area receives an annual rainfall of 1500 mm to 3000 mm mainly during the monsoon season. Thunderstorms, strong destructive wind, and lightning are common during the rainy season. The study area is well connected with the other parts of the state and is also called Gateway to Kumaon. Since the British era, this place has been acting as a commercial hub, generating employment and a supply point for hilly districts. With the increase in facilities like better health infrastructure and educational institutions, industrial establishment, and better living conditions, the area has experienced rapid population growth. Apart from these, military establishment, police training camp, barrage, roadway stations and workshops, religious buildings, and many holy shrines are also located in the area. This area also experiences landslides on different occasions; minor landslides were observed on the bank side of river Gaula and National Highway 109 (NH109). The recent ones are landslides near Don Bosco and Veer Bhatti in August 2021, which destroyed a large part of the road. Ward no. 4 (Tanakpur road) and Ward no. 5 (Ranibagh-Kathgodam) of the Kathgodam city were selected for this study (Fig. 1).

These two wards are located parallel to NH-109. NH-109 and River Gaula form the western and eastern boundaries of Ward no. 4. People settled in Ward no. 4 belong to the middle to low-income category with a population of 7585 and have a literacy rate of 75%. The ward has experienced rapid population growth of 43.9% from 2001 to 2011 (Indikosh, 2018a). Railway stations, railway staff colonies, railway maintenance offices, post office, commercial complex, veterinary hospital, and primary schools are some of the infrastructures present in the ward apart from the residential buildings. Water logging, open drainage, and lack of sanitation are common issues in the wards. Ward no. 5 has NH-109 forming its eastern boundary and hillocks on its western boundary. With a total population of 5534, people belong to higher to middle-income groups having a literacy rate of 87%. Infrastructures present in the ward are residential buildings, schools (private and government), mosques, underconstruction buildings, community gathering places, and multipurpose commercial buildings (Indikosh, 2018b). NH-109 and Tanakpur-bypass are the two main roads that connect the wards. In some places,

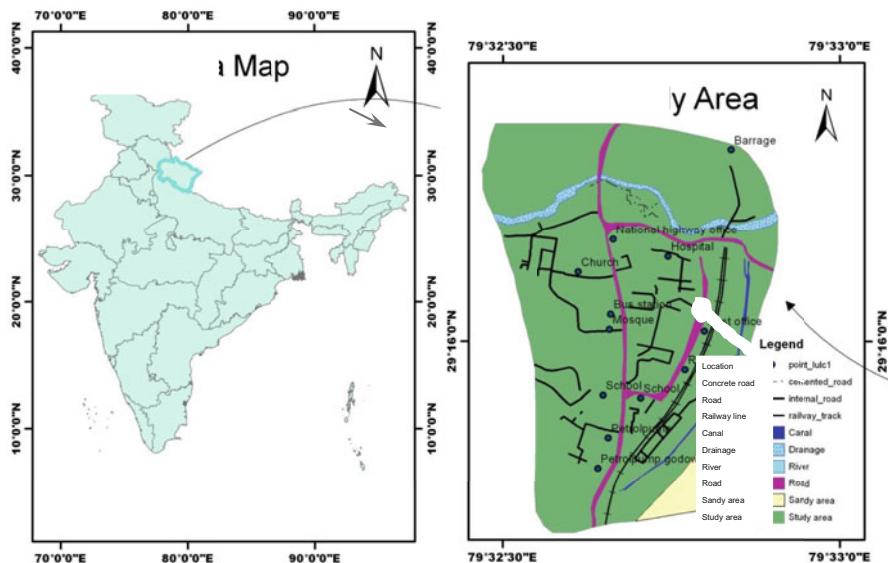

Fig. 1 Shows the basic information of the study of Kathgodam, Uttarakhand, with land use features

roads within the wards are narrow; small vehicles like two-wheelers pass through it. With the heavy inflow of tourists throughout the year, religious gatherings, and landslides, NH-109 experiences traffic jams very often.

Methodology

The study uses vulnerability and resilience indicators to assess the multi-resiliencies in the seismically prone area. The social and ecological attributes of resilience are studied to analyze the resilience of the study area, which helps to measure their capabilities and their return to normal after the earthquake hazard impacts. The methodological framework uses environmental, physical, social, and economical aspects. Within each dimension, indicators and subindicators are used to assess the resilience of a household, which are considered as the primary input to the framework and measure the risk to which a household is exposed. A bottom-up approach has been used in the framework to analyze resilience in the study area. Many studies have focused on physical indicators as the dimension for analyzing resilience (Peek-Asa et al., 2003; Bera et al., 2020), which does not provide a holistic result. To understand the resilience of a community/region, there is need to integrate the socioecological attributes (multiple interconnected factors of a specific location) in the resilience assessment along with the physical indicators. Therefore, a composite indicator-based approach is developed integrating these dimensions for analyzing

the vulnerability and coping capacities of the specific area. The environmental approach focuses on environmental factors such as drainage, soil, probability hazard, etc. of a specific area (Thanapackiam et al., 2012). Social dimensions sketch demographic details and economic characteristics such as income and livelihood profile of the households. Physical dimensions include building types, building condition, building usage, road width and accessibility, critical infrastructure, transportation, etc.

Primary data was collected from 303 samples by random sampling method through personal interviews using objective type and semistructured questionnaires. Geographical coordinates were collected using a handheld GPS device for each sample site. The questionnaire was intended to capture not only the existing status of the buildings but also a detailed socioecological profile of the area with sample location. The secondary data was collected from available literature, concerned government departments, guidelines on building construction from the city magistrate office, information on past disasters and loss of lives and property from the Haldwani Tehsil office; other details such as ward map, population, and the number of houses were obtained from Haldwani cum Kathgodam Nagar Nigam, Nainital District, Uttarakhand State. Personal interviews were conducted with the administration officials in Public Works Department, Kathgodam Railway station, and Scientists of Geological Survey of India for consensus over the level of resilience and risk with respect to seismic hazards as mentioned by the respondents in household interviews. A Digital database was created using the ArcGIS 10 software package. Detailed land use and land cover maps were created as well as various thematic maps were generated based on the indicators selected for studying the resilience in the ArcGIS 10 software from the primary and secondary data sources.

Selection of Vulnerability Indicators

Indicators are selected based on the dynamic nature of earthquake impacts, the influence of external factors, and from the past literatures. Information on indicators was collected at the household level; interaction with communities and the details of indicators were also discussed under their respective dimensions (Fig. 2). The geographical coordinate of every sample was recorded using a handheld Global Positioning System (GPS) device (Fig. 3).

Environmental Indicators

The community may experience different levels of pressures, disturbances, and various degrees of impact due to natural disasters (ODPM, 2013; UNDP, 2014). So, environmental dimensions illustrate the exposure to the earthquake event by the community (UNU-IAS, 2013; Bera et al., 2020) and its indicators such as soil texture, groundwater table, water bodies, and other hazards existing in the area. Bureau of Indian Standard (BIS) has classified the Indian mainland and islands into five seismic zones (zone II to zone VI). Zone IV and zone V comprise areas prone to very high intensity of seismic activity. Because of high intensity and frequency,

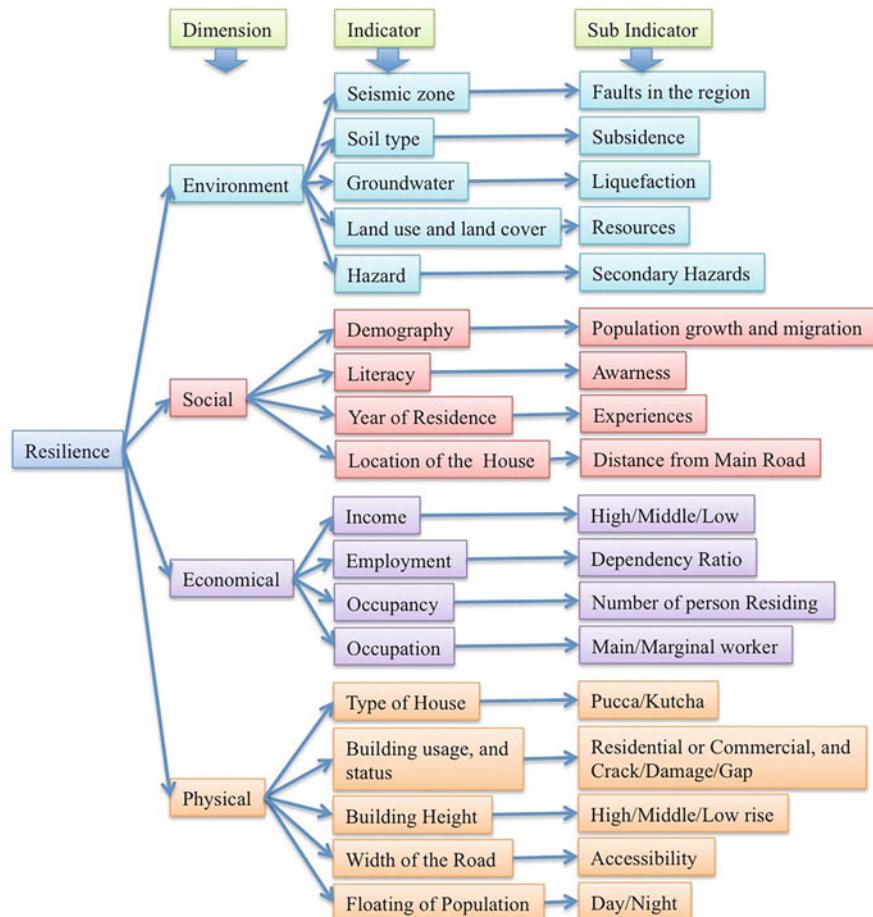

Fig. 2 Composite indicator-based methodological framework for resilience analysis to earthquake-prone region

danger to life and property is very high in these zones. Thus, a detailed study of environmental indicators of an area becomes crucial for developing an effective response mechanism to seismic activities.

Social Indicators

In the assessment of social aspects, the following indicators were studied such as dependent and vulnerable populations, literacy rate, and years of residence in the selected wards. Decreased sensory awareness, physical impairment, chronic medical conditions, and having special need and socioeconomic conditions make the elders, children, women, and differently abled persons likely to be at great risk during earthquake events, hence they are classified as vulnerable population. Education plays a key role in building the resilience of an individual as well as the community,

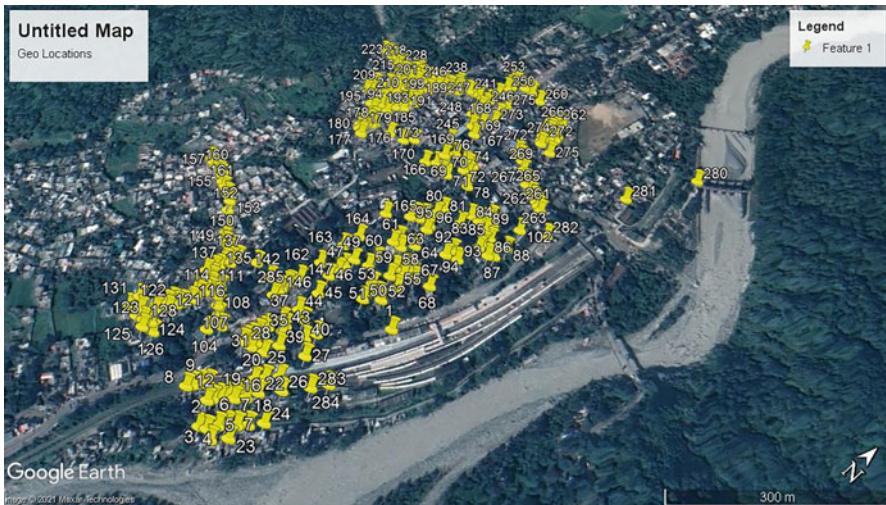

Fig. 3 Household survey locations (GPS locations overlaid with Google earth Image)

as a high literacy rate will enable a better understanding of the situation, and develops the skills and capacity to self-help and cope with the stress (Nifa et al., 2017). Thus, education helps in decreasing the level of vulnerability not only of the community but also of the vulnerable section of society. Further, lack of awareness about the existing hazards, poor construction practice, and lack of monitoring the construction practices may increase the risk exposure. Years of residence in a place are directly related to quantify the past disaster event experiences and learning from the events (Uy et al., 2011). This learning will help in developing better preparedness of the present and future generations against disasters (Yusmah et al., 2020).

Economic Indicators

The economic dimension of resilience considers the economic profile of the area and is comprised of four different indicators, namely, the percentage of both male and female employed population, occupation type and diversity of livelihood, number of occupants (or family members), and income of the population. The employed population depicts the financial independence of individuals and dependency on the economy. The ratio of the employed and dependent population shows the coping capacity of the community, as high number of employed people better access to resources which in turn increases resilience. A household with numerous occupants is more resilient as they show high adaptive capacity (Uy et al., 2011). Comparing to that, marginal workers are more vulnerable to natural disasters. Alternate livelihoods help in diversifying the options available and increase the coping capacity of the community as well as the individual when the system is pushed into a new domain by the disaster (Sinha & Goyal, 2004; Norris et al., 2008). Income is linked to economic capability, which directly affects the choice of the household like the location of the settlement. The group with high-income level is more capable of

coping with the stress induced by a disaster event than the low-income level group (Bera et al., 2020). Exposure to frequent and repeated disaster events makes the community economically less resilient.

Environmental Indicators

The following seven indicators were studied in the environmental resilience aspect namely; type of house, existing building status, year of construction, the height of the building, building usage, road width, and flow of population. Kutcha and Pucca houses are the two types found in India. The existing status of the building is evaluated by checking the existing cracks (minor cracks and major cracks) in the walls and gaps between doors and windows, which makes the building weak (Fig. 4). Structural irregularities are the outcomes of faulty design and poor workmanship, and they lead to uneven distribution of stress, overhead concrete water tanks, and the height of the building (low or middle rise buildings), which influence the evacuation time (Peek-Asa et al., 2003; Meena et al., 2013). The drainage next to the foundation can cause weakening of the foundation and soil nearby due to continuous water leakage. Buildings are used for different purposes; however, the residential and mixed-use category buildings are more vulnerable (Peek-Asa et al., 2003) due to their all-time occupancy and source of income. The flow of population defines the occupancy of the building, which varies during the day and night time. Year of construction directly relates to the use of materials and construction methods practiced. Width of the road and accessibility throughout the year increase resilience, as it will help emergency service to reach on time to minimize losses. A narrow and poorly planned road hinders the response during a disaster.

Results and Discussion

Environmental Aspects

According to BIS report (2017), the study area falls in seismic zone V (high-intensity earthquake damage zone) considering its proximity to the Himalayan Frontal Fault making the households prone to frequent earthquakes. Soil texture and groundwater table of a region play a crucial role during an earthquake. Soil textures with high water retention capacity and areas with shallow groundwater levels are prone to liquefaction (Iwasaki et al., 1984), slipping, and subsidence (Céline, 2019), which not only lead to failure of structure and roads built on it but also hinder the rescue and response activities. Soil test reports in the study area depict that the soil texture is highly porous with clay shale and boulders with ground water level below 170 ft.; thus, the site has no or low risk of liquefaction and subsidence making the household and the infrastructure highly resilient. From the observations, it is evident that the sliding of slope and landslide on the riverbank near the study site is common during the rainy season. The results coincide with the previous studies on earthquake research and assert that secondary hazards such as landslide, flash flood, fire, and reservoir-induced seismicity were triggered by the primary event

Fig. 4 Field photographs show different parts of the study area: (a) Cracks are present in the wall of the house; (b) fractures are present in the roof; (c) cracks are in the roof; (d) cracks are present in the steps and walls; (e) GPS values taken in the building; and (f) cracks are present in residential area

(Daniell et al., 2017; Céline, 2019). LULC change assessment for the study area depicts a mixed type of development including residential, commercial, railway and roadway facilities, bridges, schools, religious institutions, open public gathering places, petrol pumps, hotels, banks, etc. which are vital for the rapid response initiatives in the aftermath of the disaster and for stabilization of the area after the event. The presence of a well-maintained national highway to connect the commercial or mixed built-up areas (residential cum commercial) shows the study area has the facility to receive rapid response and rescue activities through roads. Whereas the

residential buildings are farther away from the motorable road/national highway with crowded and narrow lane areas showing that the response action team cannot reach the site as early as they reach the commercial or mixed built-up area for disaster response. Consistent with earlier research works, the necessity of land use and land cover change assessment provides an opportunity for a detailed profiling of various components that exist naturally in the environment or man-made in an area (Godschalk, 2003). It also supports in assessing the strength and weaknesses of present environment use for disaster resilience. Thus, the environmental indicators could be beneficial in understanding the vulnerability of the region and for planning efficient utilization of resources for disaster risk reduction process. Results indicate that diversifying the availability of resources such as shelters, evacuation routes, and impervious surfaces enables the people to be aware of hazard-associated response mechanism proving that it could be considered as a potential indicator to identify a resilient community in any given area.

Social Aspects

Demographic study identifies that Ward no. 4 has a population of 7585, with an annual growth rate of 43.9%, and a literacy rate of 75%. Household interviews show the average family size is comprised of 6 members. Ward no. 5 has a population of 5534 with an annual growth rate of 21.1%, literacy rate of 87%, and average family comprised of 5. Education makes individuals aware of the situation, to act promptly during an emergency, and warn others. Although the area has the pressure of rapid increase of population, the improving literacy rate shows the ability of the households to resist and cope efficiently and effectively, at present and in the future too for earthquake and associated hazards. Location indicator shows the presence of mixed-use type and commercial buildings along the national highway which indicate good coping capacity toward an earthquake event. Various research works on accessibility to buildings equipped with communication devices (TV, phone, mobile, fax, etc.) indicate to have strong social networking ability which in turn improves the dissemination of information for response and recovery (Suwanmolee, 2016). Some residential areas are congested with narrow lanes and low mobility hindering emergency response and evacuation.

Awareness on the importance of proper planning and emergency management, and finding an alternative to/ modifying the narrow lane, will help in reducing the existing risk associated with poor planning and thus will enhance community resilience. Figure 5 shows the building-wise population in the study area. The level of awareness about the natural hazards is found to be identical and higher among authorities and communities enabling them to be well prepared to adapt and cope with the stress. Respondents also reported that they have witnessed mild tremors now and then in the area but not a strong earthquake in the recent decades. However, few respondents recollect that they have felt the very severe earthquake that occurred in Nepal in the year 2015.

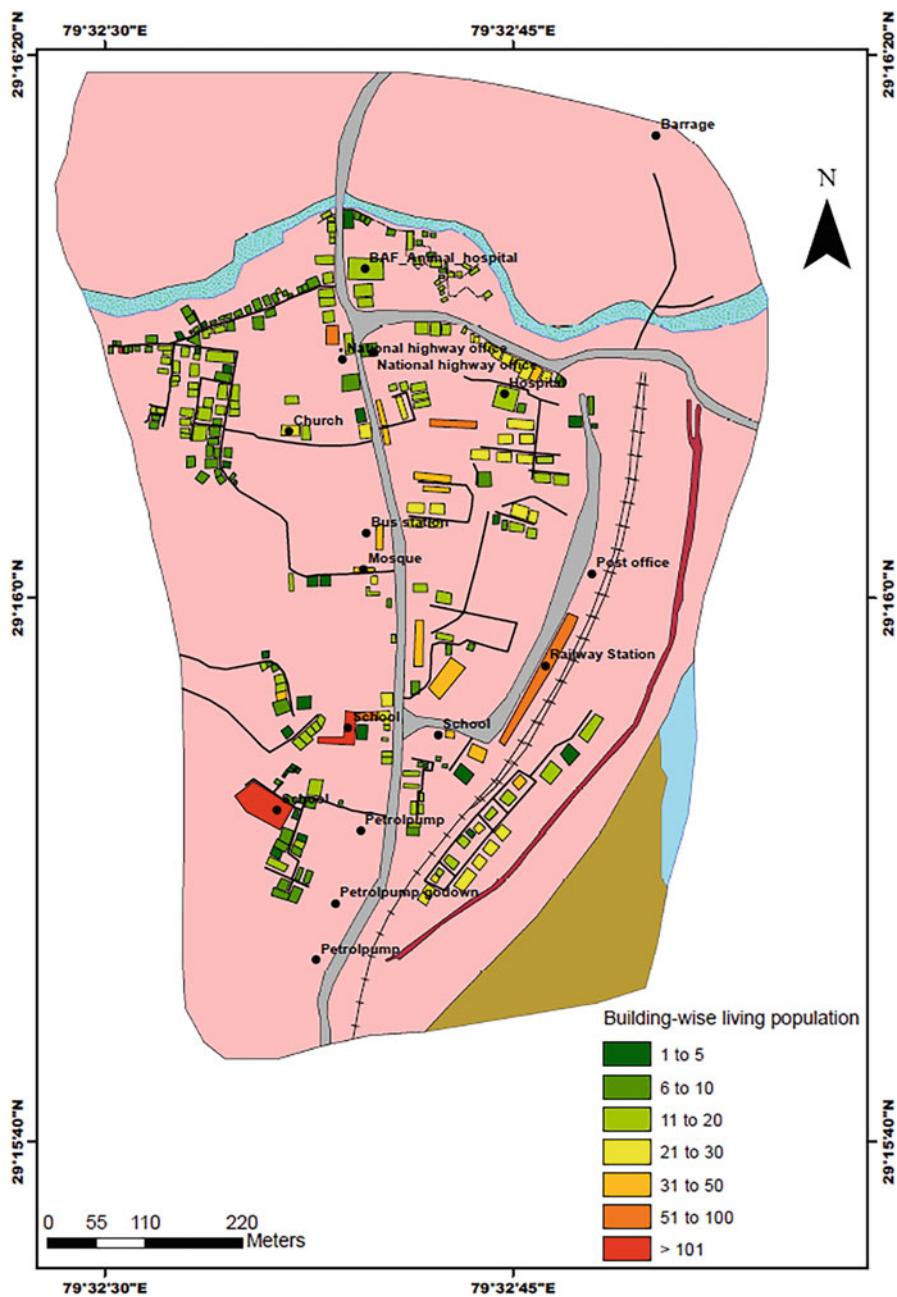

Fig. 5 Building-wise living population map of site

Economical Aspects

Income of households has a direct impact on their coping capacity. Since households were reluctant to tell their monthly income, conclusion was drawn from the past studies and census data of both wards. Ward 5 has households with high income while Ward 4 has low- and medium-income households. In the study area, there is no agricultural activity or livestock-rearing practices and the narrow range of livelihood opportunities in the region. Majority of the households are employed as either main or marginal workers in the study area. The majority of the population is employed in the tertiary sector as there is very less or no land for agriculture. Since the number of marginal workers (part-time) stands relatively low in comparison with main (full-time) workers, it shows better resilience of the community as the likelihood of having immediate disaster emergency plan or supply stocks for recovery. The average occupancy per household in Ward 4 is six and in Ward 5 is five (Fig. 6). It is understood that the household with better livelihood has the opportunity to tertiary education and those individuals are better in gathering provisions or implementing a better strategic plan to face a disaster event. With high occupancy, a greater number of individuals from a particular household can participate in economic activity. Also, with a high literacy rate the possibility of getting into an alternate occupation is higher indicating the presence of economic resilience in the area.

Physical Aspects

In the study region, the majority of the physical features are buildings that are built using concrete except for the few old buildings, which are built with conventional resources like timber, stonewall, and are short in height (present in both wards). The roof type varies with the time of construction in the area. Most of the old buildings are single storied, with tin and cement sheets as the rooftop. The new buildings are multistoried with brick walls, and the rooftop is constructed using cement and tin shades. In the study area, 71% are residential buildings, 14% are used both as commercial and other purposes and are classified under mixed use, 5% of the buildings fall under public infrastructure belonging to the government, 2% of the buildings are under educational category, and 6% fall in the category of others. All buildings are low rise (Fig. 7), with 51% buildings having ground floor only, and only 2% have second floor. With high single storied structure, quick evacuation is possible; even the elderly, differently abled, and children can be evacuated. During a building collapse, multistoried buildings tend to cause more damages to neighbor buildings, which is rare in case of single or double storied buildings. Occupancy-wise also, high-rise buildings tend to have more occupancy than the single-story building increasing the risk factor. Hence, the resilience of single- or low-rise buildings is better than high-rise buildings. The existing conditions of the building are marked under good, moderate, and low categories based on cracks present in the

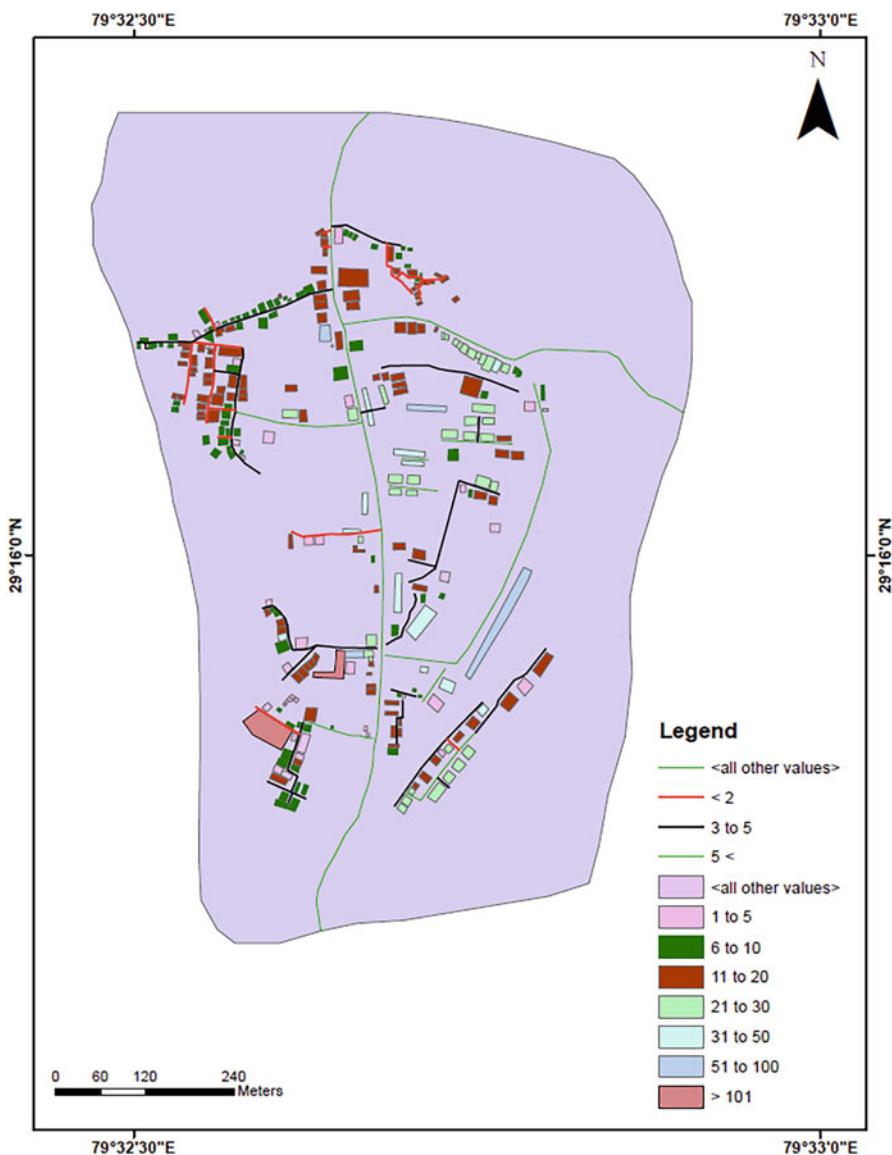

Fig. 6 Population distribution with road infrastructure of site

buildings. 44% of buildings have minor cracks, which have no or less effect on performance while 10% have major cracks and gaps in walls, doors, and windows (Fig. 8). Cracks directly affect the performance of the building. Buildings with major cracks (10%) are of main concern as they have very low resilience toward a seismic event. Since almost 90% of buildings have moderate and less cracks, the existing condition of the building shows good resilience. Total 34% of the buildings have

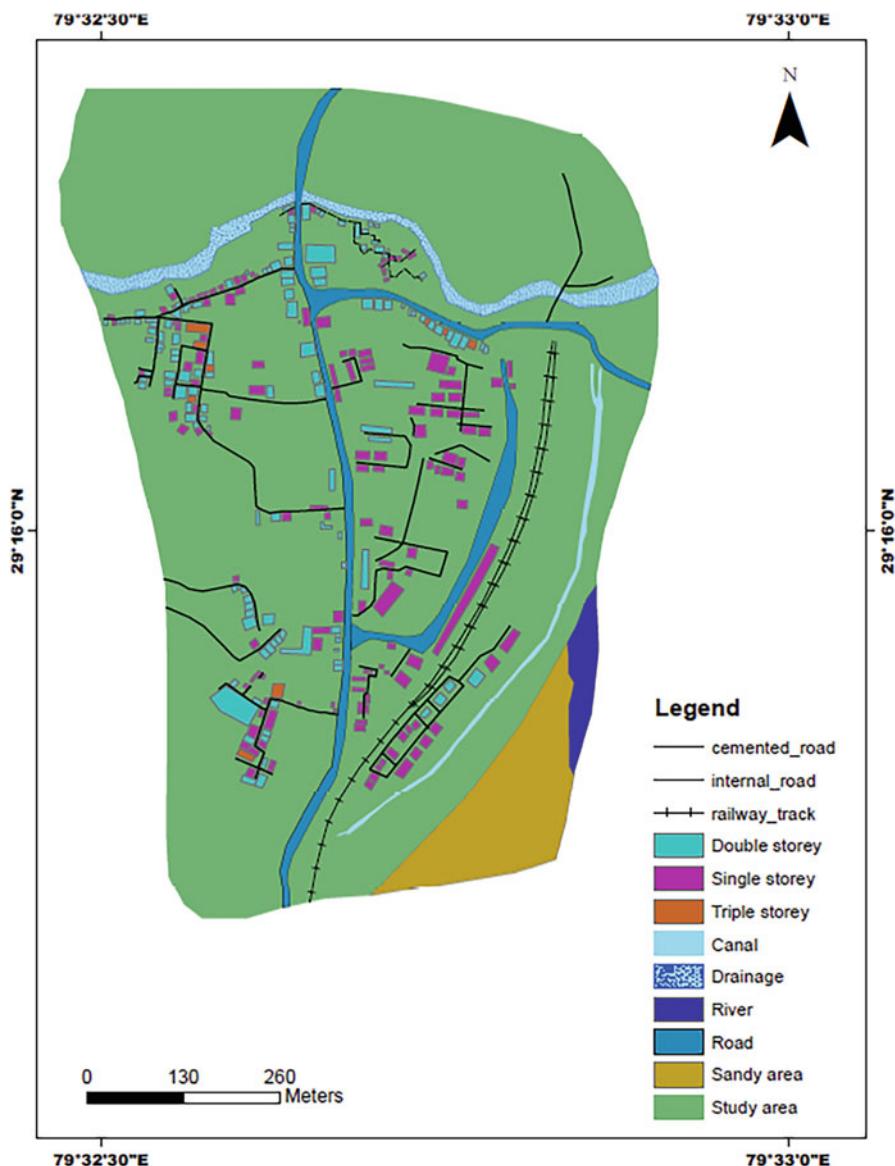

Fig. 7 Number of stories in building at study area

some form of geometrical irregularities and hanging hazards like piles of fuel wood on tilted roofs, and unused and old household stuff stored on slanted sheet roofs. Such extension with additional weight is unpredictable and increases the risk factor for the households. Using the union function of ArcGIS, the abovementioned indicators were merged. The result shows that out of the 71% of residential

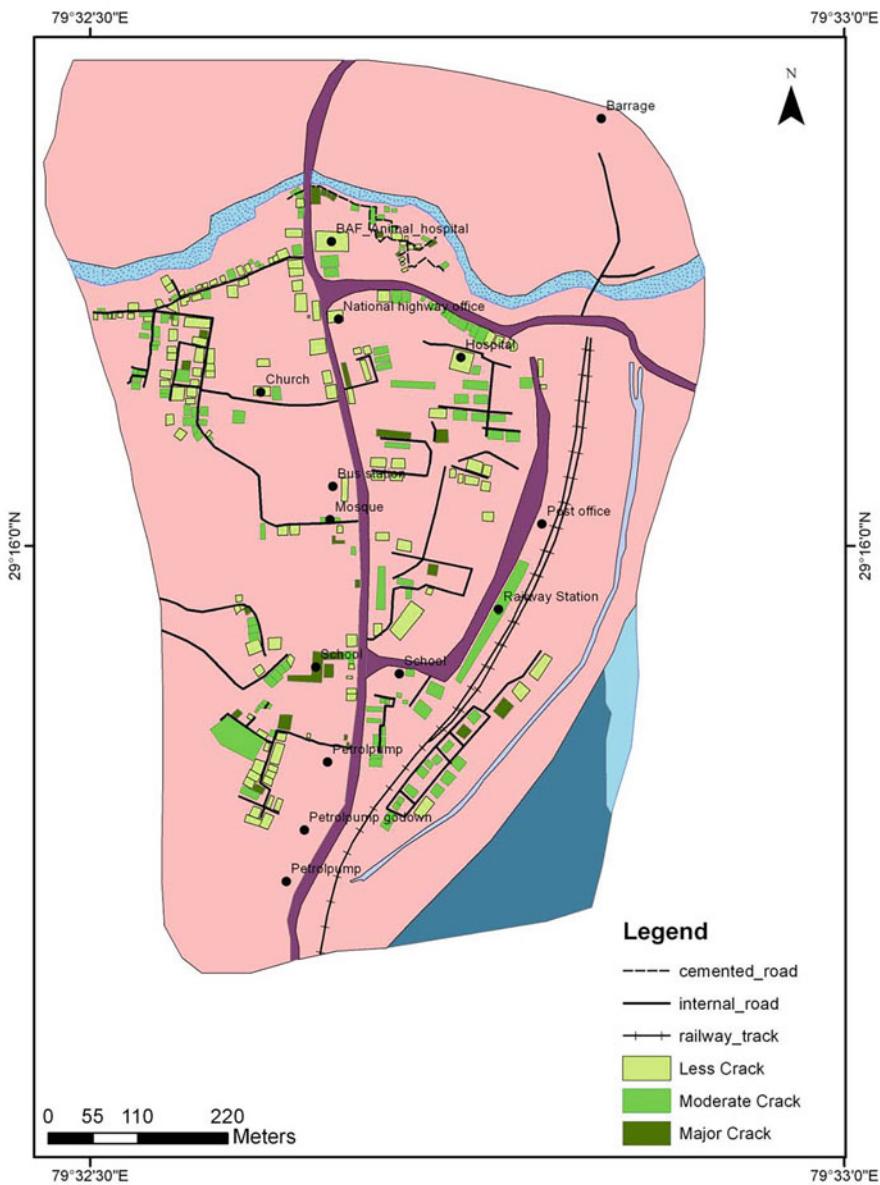

Fig. 8 Building with cracks in wall door and window in study area

buildings, 8% fall in the very high-risk category due to the presence of cracks or irregularities and hence have low resilience against seismic events. The risk factor, categories of very high-, and high-, falls in residential buildings followed by mixed-use and commercial. In the study area, there are 17 road segments having a width of

less than 2 m and in the case of emergency very difficult to assess for rescue and relief activities. In case of collapsed building, these areas will be difficult to access. Educational buildings that can be used as shelter during a seismic event are identified under the high-risk category due to lack of maintenance and attention of concerned authorities. Overall, the buildings in the study area have good physical resilience. They could further be enhanced by authorities by addressing issues like maintenance, awareness, and community participation in pre-, during, and postdisaster response and resilience activities.

Conclusion

Resilience is a dynamic phenomenon, which helps in accessing the ability of household, community resistance, and coping capacity toward the disturbance caused by stress and coming back to normal functioning from the seismic shock. Multiple features present at the community level affect the various degrees of resilience, hence assessing this in earthquake-prone areas is a complex task. The framework uses the vulnerability of the study area as its primary input, placing it under various indicators and dimensions of resilience. However, there are a few challenges and gaps in this. For example, the economic dimension deals with the economic profile of the area; due to hesitation among households, income and caste data could not be collected from most of the households. Similarly, since data is collected during working hours, the male members of the family were out for work and females of the households were not able to give data on physical dimensions like foundation type, materials used, year of construction, etc. No data on tremors felt in the area was available with the authority or with the household. So, the past experience factor under social dimension could not be analyzed. Since the migration rate has been high in the last two decades in the region, it has the potential to influence the dimensions at multiple levels. Thus, capturing its effects at the community level is difficult. Despite the above shortfalls, the study has successfully analyzed the resilience of the community at the household level. Thus, the framework can be used to analyze the resilience of other hazards in any region as it highlights the vulnerable and risk aspects of the community. With the increasing advocacy to adopt the community resilience, incorporation of insurance details and awareness level of citizen will help in improving the analysis further.

Himalayan region is sensitive toward seismic events, and inability to predict the timing, location, and magnitude of it thus will produce huge impact on human and properties. In this situation, preparedness at structural and nonstructural levels, and determining the weakness and strengths of the community, can help in reducing the impacts of earthquake. The composite indicator framework used the following four dimensions to resilience measurement, namely, physical, economic, social, and environmental. Union of the indicators shows the vulnerability and the risk associated with them has direct effects on the resilience of the household (Fig. 9).

Out of the total household surveyed, around 8% buildings in the area show high risk, implying low level of resilience as the population residing is at constant risk of casualty.

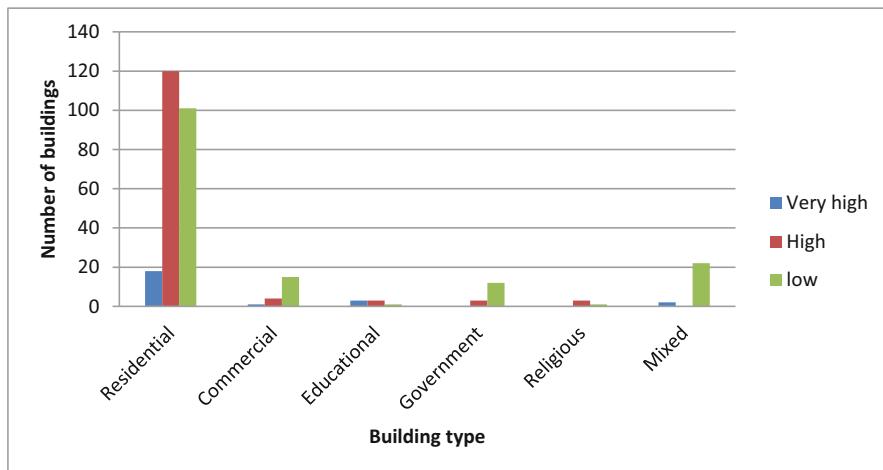

Fig. 9 Category-wise risk assessment of the building in the region

Commercial and mixed-used buildings at risk will impact the livelihood of the household, as it will affect their coping capacity by causing delay in livelihood recovery. A high education level enables individuals to acquire work skills faster, which in turn improves the adapting and coping capacity toward stress. However, the presence of narrow resources at community levels leaves less space for skill diversification.

Another important observation is the high rate of migration in the study area. Households residing in an area for years develop an understanding of the existing hazards and ways to cope with them through structural and nonstructural measures. However, in regions with high migration, these experiences are difficult to find. The high rate of migration to the low-income region and an expansion of settlement toward the riverbank put pressure on environmental and economical dimensions in the area that reduce the resilience levels of the community. With the increasing need of making resilience an integral part of disaster risk reduction, emphasis should be given to the role of community and authority. Mass awareness programs on seismic risk and good construction practices should be discussed with the community at the local level. Natural or artificial diversification of resources should be done to make the community more resilient toward stress. Region-centric intervention and micro-level study toward resilience should be encouraged. Authority should ensure implementation of building codes and training of local masonry in earthquake-safe construction practices.

Part V

Institutions and Governance

Introduction: The Importance of Good Governance in Disaster Management

53

Nivedita Haran

Abstract

Disaster management is an integral part of governance. In the introduction, attempt has been made to bring the different chapters under a common theme and to point out the role played by the public/state agencies in this regard. Disaster can impinge on the life of anyone regardless of location, class, or gender. But the ability to face a disaster improves with better awareness, robust infrastructure, and stronger financial status. In other words, vulnerability is inversely proportional to risk, hence the need to engage all stakeholders in managing disasters.

Keywords

Governance · Inter-connectivity · Non-state actors

Introduction

Disaster management is closely linked to governance. Government or the state normally takes the lead in managing disasters. Even though the philanthropic organizations or individuals, volunteers, local residents, and other non-state actors pitch in, the organized assistance in disasters always comes from the government. This is more so in the pre-disaster scenario, preparation, awareness-building, generating better ability to face the impact, and mitigation. Ancient literature indicates that post natural calamities the benevolent rulers responded by providing relief assistance, writing off loans, or reducing taxes. History also provides spine-chilling examples of rulers squeezing taxes from drought-hit farmers causing untold misery

and hardship. Historical records show how as a country under occupation food crops were diverted by the British government to feed its soldiers and countrymen during the Second World War leading to the Bengal famine that took the lives of more citizens in undivided Bengal than those who died as a result of the war. This reinforces the importance of sensitive and able governance to face disasters.

The chapters in this section deal with specific events and what measures were taken to handle these events, be it a cyclone, an epidemic, floods, or other natural and anthropomorphic disasters; the chapters also deal with the general institutional status and the need for systemic improvements to face disasters with greater alacrity and aptitude in order to ensure the loss of lives and property is at a minimal. Given this wide spectrum, the chapters perhaps are a bit eclectic as is wont to happen when the author selects the topic within the broad domain and not vice versa. However, this carries a major advantage: the reader is served an array of topics with diversity. Thus, while there is scope for the author to indulge in innovative thinking, creative conceptual analysis, and novel suggestions, there is also scope to tickle the readers' imagination while keeping an open, unbiased mind. The reader is free to glean out the administrative issues underlying the discussion without being spoon-fed into accepting the author's version alone. After all, some of the best and most practicable solutions have emerged thus. The idea to call up the District Disaster Management Officers (DDMA) in turn every week over VHF came to us when all phone lines were down and the VHF radio system was falling into disuse due to sheer nonuse. That's the beauty of a good idea: it pops up out of nowhere and survives the naysayers.

The Asia-Pacific region is the home for a diversity of natural disasters: flood and drought, cyclone and earthquake, and coastal erosion and landslide. Flood has been omnipresent in this region; with a surfeit of rivers and rivulets crisscrossing the land area and given the river flow and the density of population along the banks, the monsoon invariably brings floods in some region or the other. But, alas, it does not remain a natural phenomenon; human interventions have also been a causal factor for flooding. The urban floods are strongly human-induced: encroachment into riverbank and riverbed, filling up of ponds and lakes that were meant to act as drainage source, ill-planned bridges, etc., are all a result of increasing population density, human insensitivity and greed, and weak or ineffective administration in enforcing building and town planning regulations, and more than one paper tackle this subject. Floods caused due to cyclones are a bit more complicated, and the importance of community participation and local bodies is a moot point. The importance of flood management plans to save lives and properties and the role the public agencies play are undeniable. But the role of local volunteers, social groups, and other non-state actors is equally important initially as the first responders and later at the stage of reconstruction. At the same time, the lack of transparency within some of the non-state agencies and diversion of funds for unbudgeted functions are also worth attention.

In hilly areas, floods bring landslides which can be even more difficult to mitigate. Landslides and rockfalls have the potential to destroy lives and property and also to severely impact upon vegetation and forest. The significance of a robust and alert

administration is even more necessary here as is the need for digitized vulnerability mapping.

In a region so well endowed with high levels of precipitation, it may come as a surprise how drought occurs at fairly regular intervals in the countries in Asia and more specifically in South Asia. Drought has a strong impact on human lives, crops, and livestock; its impact on forests, cash crops, river watersheds, and water bodies is equally severe and long term. The lingering impact of drought makes it doubly dangerous as mitigation needs to be long term.

The Asia-Pacific region is carried over two geotectonic plates: the Australasian and the Asian, both of which are more active than some of the other geotectonic plates. The movement of the two plates and their rubbing against each other have created some of the most fantastic and youngest of mountain ranges, including the Himalayas that has given us Mount Everest, the highest peak in the world, but they are also the source of volcanic eruptions, earthquakes, and tsunamis. Since earthquakes are a natural disaster that cannot be predicted, the need for preparation and the role of active and dedicated administration become even more important.

Given the events and experiences of the past 2 plus years, the impact of the recent pandemic on human life, health, and livelihood is a matter of immense concern. The readers will be exposed to some interesting discussion on the impact of disasters on heritage sites. Then there are the anthropogenic disasters, viz., traffic accidents, nuclear disasters, terror attacks, and even wars. Some natural disasters get aggravated by human misdoings, and there are examples galore: fire, explosion in factories or in transport vehicles, etc. The authors have not limited themselves to simply analyzing the nature and handling of a specific disaster event: they have gone on to make their suggestions on what could be done to improve systems of administration. It is up to the readers to pick out the relevant suggestions and consider for replication on the ground or for further research.

The readership target for this handbook is rather diverse: it can be a good reference book for students, researchers, and teachers engaged in relevant disciplines; it is also targeted for public servants, especially those in this part of the region who are working at the field level or at the policy-making level; the book is also a compendium of disaster management for the corporates, activists, NGOs and INGOs, and anybody who evinces an interest in the subject. Hence, the potential readership could cover a wide spectrum, even 360 degrees.

Having been part of the disaster management teams in various capacities right from being the first responder that manages relief to reconstruction and later as the policy formulator, the question often asked is: which is the most difficult part? Frankly, no part is easy. As mentioned earlier, the state agencies are normally the first responders in a disaster event: the village officer (patwari), fire service, police, health services, and others. This will remain the primary responsibility of the state in most countries. But as we know, a disaster event response calls for alacrity, sensitivity, and access to basic infrastructure. As the DM Act, 2005, clearly states, not only is the state required to respond, it can also draw upon overarching powers to draw on any infrastructure available to ensure best services possible. The need of the hour is to save lives and property, private and public.

While drafting the disaster management policy (Kerala State Disaster Management Policy 2010; Kerala State Disaster Management Rules 2007) for the state of Kerala besides an extensive information search, various groups and stakeholders were contacted: the scientific organizations to seek data and knowledge, the universities for research work done, the media to gather data on past major disaster events, and different departments that had been engaged in the past in handling disasters, primarily home, agriculture, health, and revenue. A robust policy is a creation based on the right quality and right proportion of data, technology, and legal background all brought together with the objective of ensuring safety and security of the people. Of course, there are pitfalls: there are activist groups that have their own vested interests and who pursue their own agenda, and there are corporates keen on pushing for certain technologies or products, sometimes unknowingly but at times knowingly, and it is important to protect oneself from such pitfalls in order to ensure the policy being framed is balanced and does not deviate from its basic objective/s.

Furthermore, disaster management policies often cut across national boundaries much as climate change: more often than not the policy of a country could impact on neighboring countries or on the land, air, and water that it shares with other countries, sometimes even distant neighbors. That is where the concept of Vasudhaiva Kutumbakam or “the entire world is a single family” becomes so relevant. Rivers, mountains, deserts, and seas exist in their own right as geographical features without any concern for boundaries. Interventions on mountains could impact the weather parameters, the water flow in rivers emanating from these mountains, water-carrying capacity, rainfall, and temperature variations not only in the country that carried out such interventions but also countries surrounding it. The concept of the world being one family could not be more relevant than when viewed in the context of disaster management. The slight shift in the tectonic plate could cause an earthquake hundreds, nay, even thousands of kilometers away, and denuding of forests could affect the rainfall in countries far, far away, as indeed rivers and mountains and clouds and wind are not amenable to political divisions, nor are microbes and viruses as the world has experienced with disturbing poignancy over the last 3 years. That is why any work on disaster management has to be apolitical.

A few suggestions are apt with respect to the problems and shortcomings one finds within governance systems and outside:

- 1. Surfeit of agencies:** The most glaring issue is of the multitude of agencies working in the sector of disaster management that at times lacks unity of command and sometimes undercuts each other. Frankly, the engagement of multiple agencies is not an issue; after all, DM is the domain of many departments and falls under multiple disciplines. So, there are departments of home, agriculture, forests and wild life, environment, climate change, health, social welfare, water supply, transport, power, coast guard as well as the armed forces, and some more that are called upon to deal with it. Similarly, research on DM could be and is being carried out under a plethora of disciplines: sociology, public administration, law and governance, IT, geography, geology, botany, zoology, anthropology, health, engineering, and others. This is actually a good side as needless

compartmentalization has often been the bane of meaningful research. However, what is not acceptable is the lack of coordination between the different departments and disciplines. The wide chasms that exist are of concern. The natural scientist does not know and does not care to know the work being done in the social sciences. The researcher has no clue on the hurdles faced by the field officials or the kind of research work required for policy formulation. Digital technology remains far removed from all of the above. There is need to fill these existing gaps, and the earlier it is done the better. There is also the need to understand the role and importance of each. A holistic view would enable us to find better and lasting solutions. Take the case of floods in rural areas: The study of the gradient of the terrain, the water-carrying capacity of the river stretch, and siltation are for the natural sciences; the encroachments on riverbanks and riverbeds and strengthening the banks through embankments require engineering solution; planting of bio-shields is an environment-linked solution; digital mapping is for the IT and geography researcher; and finally an overall project to mitigate the problem of floods every monsoon is for the DDMA.

2. **Talk less, do more:** DM being an emerging area, there are a lot of new entrants hoping to find a niche for themselves. But the attempt to find fault with every work or research done is an egregious tendency. There is need to make research need-based and innovative. There are innumerable subjects waiting to be studied; yet, topics already researched are taken up again and again as this is an easier way out. DM being so intricately linked to public governance, it is advisable for research topics to be selected after consultation with the field officials and executive heads to avoid repetitive research that is a waste of national wealth in more ways than one.
3. **Look within:** Every agency engaged in DM while finding fault with other agencies should also look critically at whether his/her views fail to see the problems within the group. So, while there is need for sensitivity, there is also the need for self-introspection. Without being carried away by biased analysis, every agency needs to make an unbiased and balanced analysis. Taking the case of traffic accidents that falls in the category of anthropomorphic disasters, the per capita fatality per accident is very high in this region, one of the highest globally. This requires all stakeholders to design a plan to tackle every aspect: road design, road maintenance, road furniture and signage (engineering), speed limits, safe driving and enforcing these with utmost strictness (police and lower judiciary), better designing of vehicles (automobile design), guidelines and SoPs (policy makers), generating awareness right from a young age on road safety (education, health), and suchlike more. Similarly, that the natural disasters of yore are now getting aggravated due to man-made interventions is a worrisome fact. Without indulging in unnecessary polemics, each governing unit from the grassroots level needs to start working on it with sincerity and alacrity, be it floods caused by riverbank encroachment, landslides caused by forest denudation, or destruction of marine life due to oil spill.
4. **Non-state actors:** The disaster management setup in any country can be robust and active only if the state and all non-state actors come together for complete

synergy with each agency performing its role with dedication and responsibility to create a narrative of commitment and empathy. The state agencies by their very nature are distant and aloof. Also, a number of departments are required to deal with disasters in its various facets, some of which are as follows: home, health, agriculture, water supply, irrigation, power, environment and forest, and science and technology, all under the overall coordination of revenue and disaster management. However, managing disasters at every stage requires involvement and understanding that can only arise from a missionary zeal. It is for this reason primarily that while the state agencies perform their respective roles as laid down in the statutes, some activities can be best performed by the volunteers and philanthropic workers and other social constructs. It was found that while distributing relief material post-tsunami, much of the donated clothes were used clothes and of the type that the displaced persons would not be comfortable to wear. It was the volunteers who reported this fact to the Relief Commissioner who understood the objection and sorted out the issue. In another instance, during the panic generated due to the cracks detected in the 100-year-old earth and limestone Mullaperiyar dam in Kerala and the delay in reducing the water level, using college students and teachers, a massive awareness drive was launched by the SDMA with the local bodies along with setting up of floodlights to constantly monitor the water level and identify evacuation centers located higher than the anticipated floodline level that could allay the fears of the local inhabitants. Empathy and understanding are inalienable qualities essential in frontline workers handling disasters, be it state or non-state.

5. **Financial probity:** Fund flow at every stage of managing disasters, preparatory, relief or reconstruction, involves large amounts of expenditure. The DM Act, 2005, assigns immense powers on the SDMA and DDMA, and these powers are often delegated to block, village, and panchayat authorities. Substantial funding from the corporate sector under CSR is utilized for disaster mitigation, preparation, and relief and rehabilitation. Much of the funds are allocated and utilized under tremendous time pressure which paves the way for misuse of funds, at times unintentionally but sometimes intentionally too. There are enormous powers assigned that leave the scope for misuse of authority and embezzlement of funds. In a path-breaking case post-floods in Kerala in 1990–1991, a protracted vigilance inquiry could establish the willful dishonesty on the part of a senior district officer leading to his dismissal from service. But in the confusion that often prevails after a disaster, such cases are difficult to detect and equally difficult and time-consuming to prove. Similar or more serious misuse of funds is noticed among the non-state agencies and corporates, the latter in utilization of CSR funds, but since the kind of supervision, transparency, and auditing that exists in the public services is not present for the non-state sector, these often go undetected or uncorrected.
6. **Bottom-up approach:** The close involvement of the local bodies at every stage of disaster management, be it awareness and capacity building, relief or rehabilitation, or even sourcing of funds, can never be underestimated. There are various reasons for that: First, the resource availability and ground needs can be best

assessed at the field level. Second, accountability is best enforced at the field level; plans and guidelines are best enforced locally. Third, every activity connected to disaster management can deliver optimally when there is empathy from all stakeholders. Therefore, except major projects that cut across many panchayats and taluks or even districts, other projects are best implemented with the involvement of the direct stakeholders. Even for larger projects it is advisable to break it down into sub-projects engaging the local residents in the sub-projects. The Oachira drinking water supply project in Kollam district implemented with special post-tsunami reconstruction and rehabilitation funding would have remained effectively futile as the tail-end coastal residents would not have got the benefit of the pipe water as the water pressure remained low. It was only after a special pumping system was set up that water reached the coastal community, the community for whom the project was actually targeted under the 2004 tsunami rehabilitation program. The program to set up task forces at the panchayat/village level to handle health and hygiene, relief and temporary shelters, and awareness and preparedness is an excellent idea that started in 100 villages in Kerala but thereafter fizzled out. The three task forces could act as the eyes and ears of the local authority and would include persons available locally, such as retired teachers, public servants, nurses, etc. The task force set up for overseeing the temporary shelters can be extremely useful in ensuring safety and security of the inmates in the shelters and as a forum to redress grievances.

7. **Technology and its benefits:** These are times when technology plays a crucial role in good governance, even more so in managing disasters. Gone are the days when chain and cross-staff was used to measure the Earth's surface and height of mountain peaks. Land gradient can now be measured using digital technology, and floods are forecast using AI. Tsunami resulting from shifting of maritime tectonic plates impacts sea levels whose reach can be predicted with time period close to millisecond accuracy. The Indian National Centre for Ocean Information Services (INCOIS) is engaged in this work 24-7. The sensors placed in some of the Himalayan rivers assess the flow of water and issue forewarning on possible floods downstream. Such data needs to be collected and shared with all impacted areas and countries to alert the administration that can help save a large number of lives and properties in this part of the globe that is one of the most densely populated and is home to almost half the global population. There is urgent need for vulnerability maps based on digital data in order to make all attempts at mitigation and awareness-building more focused. The use of messaging and other apps to generate alerts on an approaching cyclone and resulting high tides even in the remote areas of Sundarbans is a case in point.

Conclusion

The problems that are starkly evident in disaster management governance are present in almost all countries as governance improves over time, through development and gathered experience. The important aspect is to learn from every experience and not

get overconfident. Also, a 360 degree oversight is crucial as is engaging all stakeholders. After all, taking mitigative measures to face a disaster and adapting to climate change are two sides of the same coin; when the two work in tandem, the result can be phenomenal. The chapters in this section help in focusing on these issues and perform one of the most important roles: learn from each other's experience.

Abstract

Community-based Disaster Risk Management or CBDRM is a “people and development oriented, comprehensive and participatory approach in reducing possible losses in the lives, properties, community resources and environment due to natural and human induced hazards” (Luna, E. M. (2007). At the center of the CBDRM framework and approach are people and communities – the analysis of people’s vulnerabilities and their individual and collective capacities in addressing the impact of the disasters and in transforming structures that have made them vulnerable to disasters. CBDRM gives primacy to building the capacities of people and communities in four aspects/processes – disaster prevention and mitigation, disaster preparedness, emergency response, and recovery and rehabilitation.

e-mail: mjtan1@up.edu.ph

This chapter focuses on experiences and lessons of selected communities, people's organizations, and NGOs in the Philippines in integrating CBDRM into processes of community development, sustainable agriculture, and participatory governance.

One of the goals of CBDRM is community resilience. This chapter also presents critical reviews of prevailing definitions of resilience and how the practices of grassroots communities and people-led CBDRRM are leading to emerging concepts of community resilience that include people's initiatives to challenge and transform structures that perpetuate their vulnerability, as well as efforts to promote sustainable development, social justice, and equity.

Community-based disaster risk management · Resilience · Sustainable development · Community organizing · People's participation

Introduction: Understanding the Philippines' Vulnerability to Hazards

According to the 2016 report of the World Risk Index of the United Nations University – Institute for Environment and Human Security (UNU-EHS), the Philippines is one of five countries deemed to be most vulnerable to natural hazards and impacts of climate change. About 20 typhoons hit the country annually, usually in the months September to December. These typhoons often result in floods causing the loss of lives and livelihoods. For example, Yolanda (international name: Haiyan), one of the deadliest super typhoons in recorded history, hit the Philippines in 2013, causing at least 6200 deaths, more than 25,000 people injured, and an estimated cost of damage to agriculture and infrastructure reaching up to Php 40 million (Bawagan et al., 2015). In 2009, three successive storms hit the country: Ondoy, Pepeng, and Santi. Ondoy (International name: Ketsana) caused massive floods in Metro Manila and nearby provinces such as Bulacan, Pampanga, Batangas, Laguna, and Rizal. Three days after Ondoy left the country, typhoon Pepeng (international name: Parma) swept through Northern Luzon causing floods and landslides. In October of the same year, typhoon Santi (international name "Marina") landed in Central Luzon. These three successive in 2009 typhoons left 961 people dead, affected 2 million families, and caused damages amounting to a total cost of USD 4.38 Billion (Polotan-dela Cruz et al, 2010).

The Philippines also often experiences earthquakes, volcanic eruptions, and landslides. One of the deadliest volcanic eruptions in recent Philippine history was the Mt. Pinatubo eruption from April to Sept 2021, causing 847 deaths. In 2006, Mt. Mayon in the Bicol region erupted. This volcanic eruption coincided with heavy rains from Typhoon Durian, which caused mudslides and lava flows killing more than 1000 people.

The frequent occurrence of disaster in the country is often attributed to its geo-physical characteristics, which makes its vulnerable to natural hazards like typhoons, earthquakes, and volcanic eruptions. At the same time, other socioeconomic factors have caused the Filipino people's vulnerability to the adverse impact of natural hazards. These factors include environmental degradation caused by large-scale mining and massive logging, poverty and unsustainable livelihoods, which have led to increasing numbers of informal settlers in high risk areas in urban and rural areas, unstrategic development planning and governance that has failed to address the structural roots of our people's vulnerability to crises and disasters.

Development workers in the Philippines believe that

disasters should be viewed not as extreme one-off events but as a manifestation of unresolved problems of development planning, social exclusion, inequity and conflicts, bad governance and unsustainable development (Polotan-dela Cruz et al. 2010, p. 2)

Development workers, environmentalists, and social activists point to the prevailing economic policies, often referred to as Neoliberal development policies, that prioritize economic growth over social development – the provision of peoples's basic needs such as food, shelter, primary health care programs, sustainable sources of livelihood; sustainable agriculture and food production; sustainable urban/rural development, etc.

From Emergency Response to Building Community Capacity for Risk Management and Resiliency to Disaster

Because of the Philippine's high level of vulnerability to various hazards, disaster risk management has become an integral part of development work of the government, civil society organizations (CSOs), and nongovernmental organizations (NGOs). In the past, the usual response to disasters mainly focused on emergency response – relief distribution and the evacuation of disaster survivors.

In the past three decades, CSOs and NGOs working with urban and rural poor communities have shifted to more pro-active, comprehensive, multisectoral, and community-based approaches to disaster risk management. Central to this community-based approach is the active participation of people in affected communities. The Citizen's Disaster Response Center (CDRC) was one of the pioneers in the formulation and promotion of a "citizenry-based development-oriented disaster response in the Philippines (Bawagan, 2011). CDRC helped establish the Center for Disaster Preparedness or CDP, a resource center for CBDRM aimed at building capacities of NGOs, people's organizations and government agencies in CBDRM (Bawagan, 2011). In 2002, CDRC and the Philippine Disaster Management Forum (PDMF) spearheaded the advocacy for a new law on disaster risk reduction that

underscored the importance of a community-based framework for disaster response (Luna, 2004). In 2009, the PDMR, along with academic institutions, environmental NGOs, and other organizations involved in CBDRM formed the DRRNet Phils whose advocacy efforts eventually led to the enactment of Republic Act 10121. RA 10121, which was passed on 27 May 2010 is:

An Act Strengthening the Philippine Disaster Risk Reduction and Management System, Providing for the national Disaster Risk Reduction and Management Framework and Institutionalizing the National Disaster Risk Reduction and Management Plan ([Official Gazette.Gov.Ph](#))

Republic Act (RA) 10121, known as the Philippine law on DRRM, underscores the need for a comprehensive, multisectoral, and community-based approach to disaster risk management. The DRRM approach in the Philippines, as mandated by RA 10121, stresses the need to undertake interventions in four interrelated components: disaster prevention and mitigation, disaster preparedness, emergency response, rehabilitation and recover. It also stresses the importance of promoting and strengthening the participation of people and communities, especially sectors most vulnerable to disasters: poor and marginalized communities, women, children, PWDs (Bawagan, 2011.)

The “community-based” approach is key in the implementation of RA 10121. CBDRM is a “people and development oriented, comprehensive and participatory approach in reducing possible loses in the lives, properties, community resources and environment due to natural and human induced hazards” (Luna, 2007). The people and their communities are at the center of the CBDRM framework and approach – the analysis of people’s vulnerabilities, their individual and collective capacities in addressing the impact of the disasters, as well as in transforming structures that have made them vulnerable to disasters. CBDRM gives primacy to building the capacities of people and communities in the four aspects/processes – disaster prevention and mitigation, disaster preparedness, emergency response, and recovery and rehabilitation.

The following sections highlight the experiences of communities in undertaking CBDRM, particularly in terms of integrating CBDRM and processes of people’s empowerment, community development, comprehensive and participatory development planning and participatory local governance, the promotion of sustainable agriculture, and the building of local resilience to climate change.

Deriving from these experiences, this chapter will also present critical reviews of prevailing definitions of resilience and how the practices of grassroots communities and people-led CBDRRM are leading to emerging concepts of resilience that include people’s initiatives to challenge and transform structures that perpetuate their vulnerability, as well as efforts to promote sustainable development, social justice, and equity.

Building People's Resiliency to Disaster Risk and Climate Change

The Hyogo framework defines resilience as:

The capacity of a system, community or society potentially exposed to hazard to adapt by resisting or changing in order to reach and maintain an acceptable level of functioning and structure. This is determined by the degree to which the social system is capable of organizing itself to increase this capacity for learning from past disasters for better future protection and for improving risk reduction measures. (UNISDR, 2005. cited in Tan, 2010, p. 208)

Resiliency is the reverse of vulnerability. By focusing on resiliency, we place greater stress on what members of the community – individually and collectively – can do for themselves and how to enhance their capacities, instead of focusing on their vulnerability to disaster (Twiggs, 2009. cited in Polotan-dela Cruz et al., 2010, p. 2)

Building People's Capacities for Disaster Preparedness, Prevention, and Mitigation

Two aspects of DRM – disaster prevention and mitigation, and disaster preparedness – focus on a pro-active, continuing processes of building the capacities of communities for preventing, reducing, or mitigating the destructive impact of hazards. The building of early warning systems and mechanisms managed by the community is a key part of disaster preparedness, which hopefully also helps in reducing or mitigating the impact of hazards.

According to the ISDR:

Early warning systems empower individuals and communities threatened by hazards to act in sufficient time and in an appropriate manner so as to reduce the possibility of personal injury, loss of life, damage to property and the environment, and the loss of livelihood. The expression ‘people-centered early warning system’ is used to emphasize that warning systems must recognize human needs and human behavior, and must be developed with local participation from women and men (ISDR, 2007, p. 46, cited in Garcia, 2010)

The experience of the Social Action Center (SAC) of Infanta in enhancing early warning systems (EWS) of the municipalities of Infanta and General Nakar, Quezon province is a wellspring of lessons in this regard. Quezon is a province in Luzon region; it is located near the Sierra Madre Mountain Ranges and the Pacific Ocean. The towns of Infanta and Gen Nakar, in particular, are located along the Agos River. Given their geographical location, these municipalities experience typhoons as well as flashfloods, mudslides, and landslides (Garcia, 2010). Every year, the province of Quezon and the whole region of Southern Tagalog is hit by a strong typhoon that causes landslides and floods resulting in deaths, destruction of farmlands and homes of farmers and indigenous peoples. In 2004, typhoon Ibiang (international name

“Winnie”) led to the death of more than 1500 people from these municipalities. Quezon province is also among the ten poorest areas in the Philippines, which makes it more challenging for the people of Quezon province to cope with and recover from disasters (Luna, 2010).

The project of SAC-Infanta and Christian Aid in 2010 installed a community-based and people-centered systematic communication and early warning system (EWS). It included the following components: (1) developing risk knowledge through the systematic collection of data and risk assessment that can be used for prediction and weather forecasting; (2) developing hazard monitoring and early warning systems; (3) developing appropriate local systems for information dissemination and communication for communicating risk information and early warning; (4) building the community’s disaster response Capability (Luna, 2010).

Part of the EWS was setting up of a water level measuring station near the Agos river to be monitored by the communities, and utilizing simple instruments such as fabricated rain gauges, water level measuring tools, and meter tapes (Bawagan, 2011). An important component of the project was the development of codes, languages, and messages about disaster risk management that were easily understood by the local people (Garcia, 2010).

To be able to install technologies and systems that could be easily managed by the communities, an important part of the project was undertaking a series of capacity building workshops. Community members, parishioners, SAC staff, and local government staff learned to use participatory tools and methodologies for the HVCA – hazard, vulnerability, and capacity analysis (Garcia, 2010). Through these trainings, each village was able to develop their own spot maps showing the hazards and resources of the villages. These maps were set up in strategic places, which were visible and easily accessible to the village members (Luna, 2010). Special trainings on search and rescue and medical first aid were also undertaken (Garcia, 2010). So as to institutionalize and sustain the monitoring and early warning processes, the project also helped strengthen the Barangay (village) and Municipal Disaster Coordinating councils, and the formation of DRM volunteer groups (Luna, 2010).

This SAC Infanta project combined high-technology communication and indigenous systems for their Early Warning Systems. It was able to do this by linking up with agencies such as the Philippine Atmospheric, Geophysical and Astronomical Service Administration (PAGASA), Manila Observatory of the Ateneo de Manila University, the University of the Philippines – National Institute of Geological Science (UP-NIGS) (Garcia, 2010).

All throughout the project, people’s consultations, meetings, training workshops were conducted to ensure that the foundation and end result of this project were empowered communities. Key to this empowerment process was helping form and strengthen local/community organizations of farmers, women, indigenous people, and youth who would be at the forefront of the CBDRM processes and programs. Some of the local farmers’ organizations that were supported by the SAC-Infanta adopted sustainable agriculture as a strategy for building resiliency in food production and agriculture. Local organizations also continued to build their capacities not only for CBDRM but also in terms of climate change

adaptability with the help of NGO partners. Some communities have set up their own Quick Reaction Teams (QRTs), Disaster Risk Reduction and Management (DRRM), and/or Climate Change Resiliency (CCR) committees to focus on the continuing processes of building capacities for emergency response, preparedness, prevention/mitigation of the impact of hazards, and climate change adaptation

Building Resiliency Through Disaster Preparedness, Sustainable Livelihoods, and Sustainable Housing

In 2006, typhoon Reming (international name: Durian) caused flash floods and lahar flows in communities surrounding Mt. Mayon in Albay in the Bicol region, killing over 3000 people and destroying almost 114,000 homes. Most of those affected were poor communities and families (Tan [2010](#)).

Responding to this disaster, the Community Organization of the Philippines Enterprise Foundation Inc (COPE-Bicol), an NGO working with communities and basic sector organizations in the Bicol province, undertook in 2010 the pilot project “Building Disaster Resilient Communities” (BDRC) in cooperation with Christian Aid. The BDRC project aimed to integrate the CBDRR framework into community development work by building the capacities of communities for disaster preparedness, sustainable livelihood, and sustainable housing (COPE-Bicol & Corpuz, [2010](#)). The pilot project focused on four pilot communities: Barangay Anislag and Barangay Taysan, two resettlement sites for Typhoon Reming survivors; and Barangay Tagas and Barangay Binitayan, two high risk communities at the foot of Mount Mayon (COPE-Bicol & Corpuz, [2010](#)).

The two high risk areas had 280 families who chose not to leave their homes despite being vulnerable to possible flashfloods, landslides, and lahar flow from Mt Mayon during typhoons. They refused to leave their homes despite the high risks because their employment, livelihood sources, and the schools of their children were within those areas. Those in resettlement sites, some of them formerly residents of these two high risk barangays, had felt that government had neglected addressing their needs in the resettlement sites, particularly in regard to disaster resilient housing, health and sanitation, and livelihood (Tan, [2010](#)).

A series of Participatory Capacity and Vulnerability Analysis (PCVA) sessions were conducted by Cope-Bicol in the four barangays. Participatory methods such as focus group discussions (FGDs), key-informant interviews (KIIs), and various participatory rapid appraisal (PRA) activities such as social mapping, annual calendar of activities, income and expenditure charts, historical timelines engaged the active participation of various sectors of the community in the PCVAs (COPE-Bicol & Corpuz, [2010](#)). All these were undertaken in the resettlement sites and high risk communities. These activities helped the communities identify the needs, disaster risks faced by the barangays, as well as available resources and capacities to help them cope with disasters.

After the PCVA sessions, orientations on DRR and BDRC, the residents in the resettlement site in Barangays Anislag and Taysan identified their vulnerabilities such as:

- 1) lack of livelihood opportunities in the resettlement site, remoteness of the sites from the town proper where their livelihood sources were, 2) lack of basic social services, including water and health services, electricity, drainage systems, good roads; 3) poor housing materials (COPE-Bicol & Corpuz, 2010, p. 199)

At the same time, the PCVA sessions enabled the resettlement residents to discover and affirm their capacities, which was key to efforts in organizing themselves as leaders in their community building and community development processes. These capacities included:

- 1) a sense of community among the households; 2) strong organizational structures; 3) skilled community workers from their local organizations and NGOs in the region; 4) safe location of the resettlement site; 5) unlimited use of the lands in the resettlement sites (COPE-Bicol & Corpuz, 2010, p. 199)

After the PCVA sessions, the residents in the resettlement sites were able to undertake activities that helped reorganize, strengthen, and consolidate their local organizations. By the end of the pilot project, the two local organizations in the two resettlement sites – the Taysan United Homeowners Association (TUHOA) in Brgy Taysan, and the United Survivors Neighborhood Association (USNA) in Brgy Anislag, were reactivated and elected their new set of officers and committees (COPE-Bicol & Corpuz, 2010). Self-help groups for the repair and maintenance of the housing units, drainage systems, solid waste management, primary health care and sanitation were also formed. The local organizations and the residents also prepared their community development plan and disaster preparedness plan (Tan, 2010). Organic gardening/urban organic agriculture was also introduced in the resettlement sites to help the households grow their local sources of healthy and nutritious food. The local organizations also held dialogues and lobbying work with the provincial government. These dialogues and lobbying work initiated by the residents of the resettlement sites resulted in the local government providing more construction materials to help build typhoon resilient housing and resources to sustain the feeding programs for the children in the resettlement sites (COPE-Bicol & Corpuz, 2010).

In the high risk areas, Barangay Tagas and Barangay Binitayan, the work focused on capacity building in disaster preparedness and risk mitigation, including the setting up of Early Warning Systems. A series of trainings on weather forecasting, on community evacuation procedures, communication protocols, early warning systems, and contingency planning was undertaken (COPE-Bicol & Corpuz, 2010). These trainings were conducted in cooperation with COPE-Bicol and other partners of the COPE Network, government agencies in Bicol such as the Municipal Disaster Coordinating Council of Daraga, the local government of Daraga, and the Municipal Social Welfare and Development Officer (COPE-Bicol & Corpuz, 2010).

These processes also led to the formulation of the community disaster action plan or contingency plan wherein the community members play major roles in disaster preparedness (COPE-Bicol & Corpuz, 2010).

The local organizations in the four barangays worked together to form a resolution to create another Resettlement site because there were many families that still needed to be relocated. This resolution was submitted to the Municipality of Daraga. Resolutions were made for them to easily access the barangay and municipal calamity funds (Tan, 2010).

Building Local Resiliency and Food Security Through Sustainable Agriculture

An inspiring story of a disaster-affected community working toward disaster resiliency and food security is that of Barangay Sianon in the town of Badiangan, Iloilo Province. Barangay Sianon is a rice and sugarcane farming community. Poor irrigation facilities, the prevalent practice of monocropping, rising costs of agricultural inputs, trader-controlled markets, frequent episodes of drought or extreme rainfall resulting in low yields and low income for the households has rendered most of the households poor (PRDCI & Tiokno, 2010). Responding to the situation of farmers in Barangay Sianon, the PRDCI, through a project with Christian Aid, helped build the capacity of farmers for disaster preparedness, reduce the vulnerability of their livelihoods to the impact of droughts and typhoons, and find a way to build their resiliency.

The PRDCI staff initiated the project by undertaking Participatory Capability and Vulnerability Analysis (PCVAs) in three sitios or subvillages in Barangay Sinoan. The PCVA centered on enabling the communities identify the hazards that made their livelihood vulnerable and determining their strengths for disaster preparedness (PRDCI & Tiokno, 2010). From the PCVA processes, the farmers realized the need to shift to drought resilient farming by practicing Integrated and diversified farming (IDFS) and sloping agricultural land technology (SALT). Engaging in SALT would help reduce landslides, and the use IDFS would promote biodiverse cropping and organic farming (PRDCI & Tiokno, 2010). Biodiverse farming would be an alternative to monocropping, which tied the farmers to only one type of crop; this made their farms and livelihood more vulnerable to adverse impacts of hazards. To further enhance their local food security and resilience during disasters, they learned to maintain home gardens, the planting of rootcrops that survive flood and droughts, legumes that have longer shelf life and seed storage (Bawagan, 2011, p. 55) The community was also trained in vermicomposting so that they could make their own organic fertilizer with readily available local resources such as rice straws and animal dung.

Being long practitioners of monocropping and chemical-based farming the farmers in Brgy Sinoan initially doubted and resisted the idea of practicing sustainable agriculture (PRDCI & Tiokno, 2010). PRDCI slowly introduced to them sustainable agriculture through a series of community-based “hands on” trainings

and by setting up demonstration plots in community nurseries so that farmers could observe and compare the crops planted with organic inputs and the crops in their farms.

Another notable undertaking on building resilience through sustainable agriculture is the farmer-led Climate Change Resiliency (CCR) program of the MASIPAG. MASIPAG is a farmer-led national network of small farmers' organizations, NGOs, and scientists promoting sustainable agriculture or what is now usually called agroecological farming.

Because many of the communities of the MASIPAG farmers' organizations are often victims of typhoons, floods, drought, and extreme climate changes, many of the MASIPAG local farmers' organizations had already been undertaking disaster preparedness activities such as setting aside rice and corn seeds, planting disaster resilient crops, and practicing DIFS. In 2013, after many farmers in Visayas and Mindanao lost family members, homes, and livelihoods because of Typhoon Yolanda, the network decided to fully institutionalize their program for Climate Change Resilience or CCR.

Essentially, the entire MASIPAG program aims to build the capacity of farming communities for disaster risk mitigation, climate change adaptation, and the promotion of climate change resilient farming through sustainable agriculture or agroecological farming practices. The MASIPAG Program is composed of the following:

Collection, identification, maintenance, multiplication, and evaluation (CIMME) – and breeding of indigenous rice and corn varieties. CIMME enables farmers to have a steady supply of seeds every planting season; with this, they need not purchase seeds and are even able to share with other farmers locally adaptable seeds ([MASIPAG Website](#)). These indigenous varieties are secured in their community seedbanks and trial farms, which has at least 50 indigenous varieties. The farmers collectively monitor and determine which among the 50 varieties are more adaptable to their local environment. The CIMME and the practice of maintaining their local seedbanks and trial farms have made many MASIPAG farmers self-reliant in terms of having their own rice and corn seed reserves ([MASIPAG Website](#)).

The DIFS/DSAE (diversified and integrated farming systems/developing sustainable agro-ecosystems) program ensures that farmers grow not only rice but also vegetables, rootcrops, fruit trees, poultry, and livestock – these provide diversified food sources, better nutrition, additional sources of income, and food security during disasters ([MASIPAG Website](#)).

The local marketing and processing support (LMPS) program enables farmers to process vegetables, fruits, root crops, and herbs so that they can stock food with longer shelf life. During the pandemic, the women farmers of MASIPAG were able to produce noodles from squash, create turmeric powder, lagundi syrup, and other herbal medicines they used to cure common ailments during the Covid 19 pandemic. They were able to share these herbal medicines and healthier processed food with health frontliners and other community members. Food processing also enabled them to have additional sources of income ([MASIPAG Website](#)).

The conduct of education and training sessions on DRR and CCA, and on sustainable agriculture, are also part of the MASIPAG CCR program. Through the

trainings, farmers' organizations have developed their local DRRM plans, which include having their own seed reserves and their own calamity funds that they use for their emergency relief distribution. During the Covid 19 pandemic, some of the farmers' organizations were able to use their own food and seed reserves and calamity funds for creating their mobile hot meals and feeding programs that they conducted alongside trainings on community health and nutrition (Tan, 2021).

Underlying all of these programs is the MASIPAG farmers' practice of bayanihan – through seeds exchange, sharing of their surplus rice and vegetables to communities during disasters and during this Covid 19 pandemic.

Masipag farmers are aware of the root causes of their vulnerability to disasters and climate change – development policies that have not prioritized the socioeconomic well-being of small farmers, development aggression (open-pit mining, construction of large dams, conversion of rice lands into industrial farms/corporate plantations of cash crops such as banana, pineapple, rubber, etc.,) the massive promotion of GMOs such as GM corn and rice, which are dependent on chemical agricultural inputs that have harmed people's health and the environment.

As such, the key component of MASIPAG's CCR program is policy Advocacy. Through face to face or online sessions via mass media (radio) and social media platforms, MASIPAG conducts educational sessions or issues discussions on disaster management, climate change adaptation, and climate justice. Through their education and advocacy work, MASIPAG has been able to work with Local Government Units (LGUs) in enacting ordinances promoting organic farming, ordinances that ban the entry of GMOs that promote the use of chemical inputs that contribute greenhouse effect.

Reducing the farmers' vulnerability means building the adaptive capacity of the farmers and their communities in terms of strengthening their capacity in organizational building, providing access to resources, skills and technology, and changing practices, behavior and livelihood strategies (PPT presentation on MASIPAG CCR Program, MTDP, Feb, 2022)

Institutionalizing CBDRRM into Local Governance

RA 10121 is a major milestone in ensuring that communities play lead roles in DRRM and CCA. However, the enactment of this law is not a guarantee that the mandated local, regional, and national structures, processes, and budget for responding to disaster is effectively functioning. This was one of the major findings of the research project between the Dept of Science and Technology (DOST) and a team of faculty and students from the Dept of Community Development, College of Social Work and Community Development, University of the Philippines Diliman (DCD-CSWCD, UP Diliman). The action research was conducted a few months after the deadly and destructive typhoon Yolanda (Hayan) hit the Philippines in 2013.

The research project studied the experience four barangays affected by Typhoon Yolanda. Two barangays – Brgy Banaag in Guiuan, Eastern Samar, and Brgy

Ezperanza in San Francisco, Camotes Islands, Cebu – were hit by typhoon Yolanda but had low casualties and damages. The other two barangays – namely, Brgy Candahug in Palo, Leyte, and Brgy Sapao in Guiuan, Eastern Samar – suffered high casualties and damages. The action research project documented, analyzed, and drew lessons from the disaster preparedness structures, mechanisms, and measures that were present (or lacking) at the household, village, municipal level, which enabled (or did not enable) communities to respond to the impact of typhoon Haiyan. It studied how various activities and institutions (communities, LGUs, CSOs, individuals, academe) responded to the impact of the typhoon, the factors that facilitated or hindered the effectiveness of the response (Bawagan et al., 2015).

The research study showed that there was a low level of disaster preparedness in three of the four barangays, particularly Barngays Sapao, Banaag, and Candahug (Bawagan et al., 2015). The DRRM structures, institutional mechanisms, and DRRM plans mandated by law were not very functional in these barangays at the time of the action research. Much of the work focused on emergency response.

Only one out of the four barangays that were studied – barangay Esperanza in the municipality of San Francisco, Camotes Island, Cebu – experienced low casualty and damage because their CBDRRM structures, processes, and plans were in place. A key factor in their ability to survive typhoon Yolanda was their “purok system,” a community-based mechanism, which divides the villages into smaller units for communication and information dissemination during disasters and for mobilizing the communities for various service deliveries of the local government unit (Ponce de Leon, 2021). With the help of Plan International, the San Francisco Mayor was able to institutionalize CBDRRM using the “purok system.” The municipal DRRM office also had a permanent position office, office staff with DRRM plans, programs, and budget (Bawagan et al., 2015).

Being an *action research* project, the team from DCD-UP Diliman proceeded to respond to the identified needs of the four barangays by conducting a series of orientations, training workshops, and planning sessions on CBDRRM and CCA.

In the three barangays, which demonstrated limited disaster preparedness, an orientation on Community-based Disaster Risk Reduction and Management (CBDRRM) and initial CBDRRM planning was undertaken. The training introduced the barangay members to the basic concepts of DRRM: disaster preparedness, emergency response, disaster prevention, disaster prevention and rehabilitation, the different community, municipal, regional, and national DRRM structures and processes, and the content of the DRRM Act of 2010 of RA 10121. It also provided an overview of the processes and principles of community-based approaches to DRRM with a stress on the point that at the heart of DRRM are the people – building the people and communities’ capacities and promoting people’s participation in CBDRRM. The trainings led to the formulation of initial BDRRM plans and the formation or revitalization of their BDRRM councils of BDRRMCs

For Barangay San Francisco, Cebu, which was already practicing CBDRRM, the training focused on orientation and planning toward climate resilient agriculture and fisheries. It introduced the participants to key concepts in climate change and climate

change adaptation, and to ongoing climate change adaptations and climate resilient agriculture efforts of other municipalities (Bawagan et al., 2015.)

San Francisco gained international recognition, including the UN Sasakawa Asawd for Disaster Reducation in 2011 for their “purok system” in managing disaster risks (Reliefweb, 2011). At the same time, the purok system, used not only for the CBDRRM but as an LGU mechanism for service delivery and knowledge transfer, is being reflected upon and critically reviewed for its “top-down approach.” The purok system effectively spared the people of Barangay Esperanza from the destructive impact of Typhoon Yolanda. At the same time, as a community-based approach for people’s empowerment and governance it can be further enhanced by more spaces and opportunities for bottom-up people’s participation in decision making (Ponce de Leon, 2021).

A major output of the action research was the surfacing *of definitions and dimensions of “resilience” from the community members themselves*. Some of the definitions that surfaced include the following:

- *Having a safe and secure location*
- *Availability of basic services for health and shelter and economic resources such as land, income, savings, and livelihood options*
- *Solidarity among community members as expressed through damayan, bayanihan, protecting each other, where individual as well as collective safety are intertwined*
- *Having strong faith and spirituality*
- *Leadership felt by the community members; community members are cooperative for the common good*
- *A culture of safety and preparedness*
- *Environmental integrity to provide for the livelihood of community members*
- *Risk transfer mechanisms, e.g., insurance for crop, livestock, and life*
- *Enabling policies* (Bawagan et al., 2015, p. XIV)

These definitons show that the people in the barangay were aware of the root causes of their vulnerability – their homes were located in areas that were vulnerable to floods, typhoons, storm surges; their sources of income/livelihoods were unstable; they had limited access to basic social services; etc. These recommendations also show that the communities were aware of the responsibility of the government as duty bearers and that they have the right to call on their governments to provide basic social services and create conditions that would promote sustainable livelihoods. Likewise, these definitions of resilience from the people showed their awareness of the critical roles of indigenous forms of community support, collective action, and social solidarity locally known as damayan, bayanihan.

This action research also generated key recommendations for barangay officials and members for the LGUs, National Government Agencies (NGAs), the academe. Some of the key recommendations include:

1. For Local Government Units (LGUs) and National Government Agencies (NGAs) to continue developing the BDRRM plans and building the BDRRMCs
 2. Developing DRRM-CCA concepts and key messages using local and visual language
 3. Given the archipelagic character of the Philippines, to develop effective communication systems within, between the various islands and mainland
 4. Integrate DRR-CCA into school curricula
 5. Mainstreaming DRR-CCA into government structures and policies, emphasizing the need for pro-active rather than reactive programs, strategies, and policies (Bawagan et al., 2015)
-

Conclusion: Key Lessons in Understanding Resilience, Agency, and Social Transformation in the Context of CBDRRM Practices

In recent years, the term “resilience” used in the context of disaster risk management has been criticized for being “apolitical” or even for maintaining the status quo with its goals of “bouncing back” or “returning to its state prior a disturbance” (transition and resilience, p. 9), (climate change) adaptation, etc. According to Henfrey and Giangrand, Naresh in their article “Resilience and Community Action in the Transition Movement,” such definitions of resilience seem to

seek to normalize and perpetuate existing imbalances of power and/or transfer responsibility for environmental and social damages from their perpetrators to their victims (Henfrey & Giangrand, 2017, n p. 95).

Through conscientization and awareness raising, participatory processes (e.g., PCVA, etc.), and community organizing, the basic sector organizations and communities are more aware of the roots of their vulnerability as well as their collective capacities to address, challenge, and transform deeply rooted structures and policies that have perpetuated people’s vulnerabilities to hazards, climate change, and other social crises.

Increasingly, grassroots movements are redefining the concept and goal of resilience. An emerging concept is “community resilience” with the following characteristics:

Capacity for self-organization, suitable infrastructure, economic diversity and innovation, relationship to place, and the capacity to exercise agency through appropriate forms of leadership, suitable knowledge and skills and means to develop these further through learning, appropriate values and beliefs, engaged governance, and the ability to mobilise collectively through social networks (Helen Ross in Transition, p. 104)

These emerging definitions of resilience are reflected by the experiences and practices captured in the short narratives above, which underscore the following:

1. Grassroots/basic sector communities/organizations as agents, as partners, not only as disaster victims or survivors

It is important to go beyond the sense of being a victim or disaster-survivor and move to becoming an agent of change or acquiring a sense of agency (Tan, 2010)

Hence, for instance, the farmers' organizations of MASIPAG address the immediate concerns of emergency response, disaster prevention/mitigation, and climate change adaptation. At the same time, they are active in the campaigns for climate justice – actively joining local and international campaigns advocating for initiatives from the international community to compel industrialized countries to reduce greenhouse gas (GHG) emissions by shifting to renewal energy and more sustainable approaches to industrialization, and imposing sanctions on countries that caused massive environmental destruction especially in developing countries like the Philippines because of their unsustainable industries and businesses that prioritize profit over people (MASIPAG Luzon, 2017)

MASIPAG, like many other NGOs and CSOs in developing countries, is also undertaking researches and educational campaigns to raise people's awareness on the impact of chemical/industrial farming on the environment and food security of poor countries, researches on local sources of renewal energy, and suspension of policies that have adverse effects on people's health and livelihoods, the environment, such as the promotion of the construction of large dams, open pit mining, coal fired thermal plants and the like

2. Community organizing as the foundation of people-led CBDRRM and processes of building community resilience

Corpus underscored that community organizing is the key element in the BDRC pilot project and that all aspects – community social preparation, participation, mobilization – are linked to CO work. The BDRC project demonstrated that DRR and CO complement each other and must be integrated. In this project, integrating the community organizing process into DRRM helped in:

- (a) *Building a strong foundation for attaining community resilience among partner communities through capacity building activities and awareness raising*
- (b) *Helping vulnerable groups gain their confidence and realize their capacities for sustained active participation in program implementation*
- (c) *Development of shared ownership for the project among partner-beneficiaries*
- (d) *Surfacing and documenting the capacities and vulnerabilities of the residents in the four barangays, which formed the bases for their contingency plans and DRR plans* (COPE-Bicol & Corpuz, 2010 p. 206)

3. The importance of promoting local and indigenous processes of community/ collective – action such as “bayanihan” and “damayan”

In our conversations with the people in the resettlement sites Barangay Anislag and Barangay Taysan, they expressed their concern over families who were still in the high risk communities. One of the Mothers in the resettlement site said:

After gaining knowledge from the trainings, I felt a spontaneous willingness to re-echo (the trainings) to the communities we came from, especially to neighbors who are still living in the disaster prone areas. Now, I would like to involve myself more in community drills, QRTs and how to respond (Tan, 2010, p. 212).

Drawing from the same conversations with the people in the four barangays involved in the BDRC pilot project in Bicol, our research team realized that:

A basic element of the Filipino's resiliency is our fierce belief in the spirit of damayan and bayanihan, the power of collective community action that will always help us survive and rise up from disaster and tragedy. These are testimonies to the triumph of the collective human spirit, a testimony to the Filipino's brand of community resiliency (Tan, 2010, p. 213)

Learning from these stories of grassroots communities and people's organizations, we see that at the core of people-led CBDRM and people-led processes of achieving resilience are still the basic and fundamental processes of social awareness raising, community organizing, people's collective action, social solidarity for social justice, and sustainable development.

Abstract

Resilience thinking argues that disaster governance must consider the drivers such as resource management, development, efficiency, and sustainability as root causes of vulnerability to disasters and devise strategies to address them. It aims at building community capacities to cope with disasters in the short term and mainstreaming and integrating disaster risk reduction strategies with developmental priorities in the long term. This chapter presents a case for the need of resilience thinking in disaster governance and assesses policy framework of disaster governance in India vis-à-vis resilience thinking. It argues for mainstreaming resilience thinking in a manner that leads to judicious resource management and sustainable development.

Introduction

Disasters occur when community capacities are defied by forces more powerful than such capacities. Discourse on disaster governance evolved from response- and relief-centric approach to building capacities for prevention, mitigation, and preparedness to cope with disasters. The words vulnerability and resilience became prominent in this discourse. Vulnerability is understood as lack of capacities to cope with disasters and resilience is promoted as the ability to withstand disasters. Major global initiatives, treaties, agreements, and conventions reiterated this understanding of disaster resilience. The institutional frameworks of disaster governance of individual countries joined the bandwagon and built capacities for managing disasters.

If disasters are understood as events that have nothing to do with development and can be managed with a certain degree of capacity once they strike, such flawed understanding will do more harm than good. Development and disasters are related intimately. Not only are disasters the outcomes of our development efforts, but they can also wipe out years of development gains (Thompson, 2020; NDMP, 2019). Disasters are both the cause and product of development. The more a society embarks on the path of economic development, the greater is the vulnerability, and also the chances of disasters occurring. The fundamental flaw with current disaster understanding is that it doesn't consider development, vulnerability, and disasters as interrelated notions. This understanding must be reconsidered.

This chapter argues that disaster governance must consider the drivers such as resource management, development, efficiency, and sustainability along with the strengthening of disaster management capacities for achieving effective disaster risk reduction. This argument goes beyond building capacities for disaster preparedness and mitigation to a fundamental reconsideration of the development aspirations of individual countries and devising mechanisms to reduce vulnerabilities caused by the above mentioned drivers. It questions the very idea of sustainable development that talks about the unattainable task of balancing economic growth and environmental conservation. Popularly known as resilience thinking, this approach exposes the dangers of understanding disasters as “unavoidable occurrences that can be managed.” Disasters are neither unavoidable nor can be managed. This approach advocates that certain disasters can be avoided if the underlying drivers are recognized and addressed in time. It also argues for creating institutional frameworks of disaster governance for understanding and addressing the root causes of vulnerability, which eventually results in disaster resilience. The remainder of the chapter discusses the notions of disaster governance, resilience thinking, and how disaster governance is affected by resilience thinking. It also discusses resilience thinking in disaster governance in India as reflected in the policy framework.

Disaster Governance

Disaster Governance, a subset of Governance reflects the paradigmatic shift in disaster management from state-centric, hierarchical, monopolistic administrative structures and processes to plural, multi-actor, multi-institutional collaborative

mechanisms in which decision-making powers are dispersed outside government (Tierney, 2012; Thompson, 2020; Shahat et al., 2020). Management of disasters is the function of governments all over the world traditionally. In this traditional disaster management, governments assume proactive role from disaster prevention and preparedness to mitigation and response, set up institutional mechanisms from national level to local level and endow them with regulations and resources for effective disaster risk reduction. Communication flows in a hierarchical fashion from a centralized planning agency to the field offices that follow command and control orders meticulously. In simple words, disaster management functions on bureaucratic lines.

Effective management of disasters is beyond the capacities of governments as routine administrative structures, bureaucratic rules, and practices result in delay, prolong the processes and act as hindrances (Gupta, 2003). The traditional state-based action is no longer sufficient to address modern day disasters. This paved the way for a paradigmatic shift from traditional disaster management to decentralized, de-bureaucratized, plural, and collaborative institutional structures, processes and mechanisms with the active involvement and participation of non-state actors (Tierney, 2012). This paradigmatic shift is referred to as Disaster Governance.

Disaster Governance comes under the rubric of risk governance (Tierney, 2012). It refers to “a set of structural arrangements and processes through which coordinated decision making and action takes place across various institutional settings” (pp. 343). It goes beyond governmental settings, powers, processes, instruments, and capacities by engaging non-state actors of market and civil society operating at all levels and scales. Disaster Governance is also conceptualized in terms of the capacities of the human societies in taming risks related to disasters. This conception gives scope for framing disaster governance as a societal intervention that aims at mobilizing resources, skills, abilities, and knowledge “to translate risk reduction processes and decisions into collective action among multiple actors” (Thompson, 2020).

Disaster Governance consists of a set of norms (laws, regulations, standards, and frameworks), institutional actors (state and non-state actors such as government, businesses, and NGOs), and practices (preparedness, mitigation, response, collaboration, funding, etc.) that are designed to cope with disasters caused by natural, human, and technological agencies (Tierney, 2012). Natural agencies include natural forces like earthquakes, cyclones, tsunamis, floods, etc. Human agencies are the deliberate acts of human beings such as terrorism, naxalism, etc. Technological agencies include technological forces like transport accidents, nuclear explosions, etc. Disaster Governance aims at building disaster response capacities through partnerships, training communities to be disaster resilient, and putting forth multi-faceted disaster response mechanisms in saving lives and property. It also reflects the notion that weak disaster governance capacities are the primary drivers of disaster risks (Gupta, 2018).

Disaster Governance is shaped by both state actors, non-state actors and a variety of socioeconomic and political forces. Particularly, globalization is one prominent force that heavily influences Disaster Governance. International aid agencies,

monetary organizations, and regulatory agencies such as World Bank, IMF, and UNO are important factors that shape the contours of Disaster Governance, especially of the developing countries (Tierney, 2012; Shahat et al., 2020). Unlike developed countries that are properly equipped with disaster governance capabilities, the developing countries lack them. Literature on disasters argues that developing countries are inadequately equipped with resources, capacities, institutions (mainly local and community), and finances to put robust resilience mechanisms like those of developed countries (Thompson, 2020; Shahat et al., 2020). Coupled with the governance deficits such as corruption, lack of respect for the rule of law, weak environmental regulations, and lack of meaningful public participation in decision making, the weak nature of regulatory systems of developing countries increase the vulnerability to disasters in such societies (Guha, 2014; Syal et al., 2021). For overcoming these challenges, the developing countries are dependent on international agencies and institutions for disaster-related assistance. Newly emerging Non-Governmental Organizations and Civil Society Organizations from global to local level also have their effect on Disaster Governance (Syal et al., 2021).

Disaster Governance has become indispensable in the sphere of disaster risk reduction. It cuts across all the institutional and societal domains. It strategically links individual, institutional, and societal activities and arrangements with disaster-related problems and solutions for accomplishing the Disaster Risk Reduction mandate. It is the precondition for achieving vulnerability reduction and long-term disaster resilience. It facilitates disaster management actors in preparedness, mitigation, response, and recovery. In short, a government's ability to effectively address disasters depends on its ability to create sound governance systems and use their benefits (Thompson, 2020).

Vulnerability, Resilience, and Resilience Thinking

Vulnerability refers to the inability or diminished capacity of an individual, group, community, or government to anticipate, cope with, resist, and recover from disasters (Alexander, 2013; Thompson, 2020; McKeown et al., 2021). It is defined as the “propensity (of a society or community) to be harmed (by a hazard or disaster) but not being able to deal with the harm (causalities, property loss, or business interruption) given the social processes creating and maintaining that propensity” (Kelman et al., 2016, pp. 130). Traditionally, vulnerability was perceived as a condition caused by natural/environmental processes independent of human intervention or contribution. But it is realized that vulnerability is caused by a combination of social processes (cultures, traditions, and ideologies) and economic processes (poverty, income, and livelihood) in addition to natural processes (UNISDR, 2017). Human beings incessantly contribute to these social, economic, and physical processes and increase the susceptibility of individuals and communities to disasters. Since vulnerability is a product of multiple processes, measures required to address it should be multipronged. The focus should be on eliminating the conditions causing

vulnerability along with empowering communities with capacities to cope with disasters (Thompson, 2020).

The term resilience occupied the serious attention of scholars of disaster research (Walker & Salt, 2006; Alexander, 2013; Chandler, 2014; Thompson, 2020; McKeown et al., 2021). It refers to “the ability of a system to absorb disturbance associated with disasters and still retain its basic function and structure” (Walker & Salt, 2006, pp. 1). United Nations International Strategy for Disaster Reduction defines disaster resilience as “the ability of a system, community or society exposed to hazards to resist, absorb, accommodate to, and recover from the effects of a hazard in a timely and efficient manner, through the preservation and restoration of its essential basic structures and functions” (UNISDR, 2009, pp. 10). These definitions consider the entities that respond to a disaster as “systems that strive to preserve and restore their integrity.” But, according to Thompson (2020), resilience is a system’s ability to “morph into a new condition to survive as it adapts to its changing or changed environment” (pp. 54). He viewed the system as a non-neutral, complex entity that constantly changes.

Of late, the notion of “resilience thinking” is evolving in disaster literature. Resilience thinking considers societies as complex systems that are in constant state of flux and resilience as a dynamic interplay between stability and change (Thompson, 2020). Resilience thinking aims at management of resources of a social-ecological system in a manner that continually adapts itself through cycles of change while trying to maintain system integrity at the same time. The definition given by Intergovernmental Panel on Climate Change aptly captures the essence of resilience thinking. It defines resilience as “the capacity of social, economic, and environmental systems to cope with a hazardous event or trend or disturbance, responding or reorganizing in ways that maintain their essential function, identity, and structure, while also maintaining the capacity for adaptation, learning, and transformation” (Rangwala et al., 2018, pp. 10). Simply put, resilience thinking is premised on the question of “how resilience in governance systems can be strengthened through the processes of social learning and adaptation” (Duit, 2016, pp. 368).

Approaching Resilience: Rethinking Development

On the basis of how vulnerability is perceived by a society, resilience thinking can be divided into two approaches. One approach argues to build capacities of disaster resilience without considering the underlying drivers of vulnerability that lead to disasters. Capacities and capacity building occupies central position in this approach. Capacities refer to the ability of a community to manage, accommodate, and adapt to disasters. Capacity varies from individual attributes like skills, knowledge, and leadership to collective attributes such as resources, infrastructure, and relationships (UNISDR, 2017). Capacity building aims at equipping individuals, communities, and governments with capacities (skills, knowledge, and resources) to make them disaster resilient.

According to this approach, it is impossible to identify the causes of vulnerability of a system to disasters because of the complexity and hence, any such attempt to fix vulnerabilities would actually result in more vulnerabilities as unintended consequences of such attempts (Chandler, 2014). Rather than identifying and addressing the root causes of vulnerabilities, this approach considers them as random unavoidable occurrences, also called as “black swan” events (McKeown et al., 2021) (‘Black swan’ events are those events which could not have been foreseen prior to their actualization. The global financial crisis of 2007/08 and COVID 19 Pandemic are examples of black swan events.). It takes more resources to explore the causes of vulnerability than to address it by building capacities due to the complex nature of the system. Hence this approach argues that it is better to adapt to complexities of the system and build capacities to respond to disasters through agency (Chandler, 2014). David Chandler proposed the notion of post-liberal agency-centric capacity building by taking it away from the purview of community (McKeown et al., 2021). In simple words, resilience thinking in this approach shifts focus from efforts toward understanding and reducing vulnerabilities to capacitating systems to adapt to and cope with change. It aims to equip societies with predesigned coping responses that can be put into effect once a disaster strikes.

The other approach perceives that vulnerability is the main driver of disasters and hence communities must work toward making their societies non-vulnerable by identifying and addressing the drivers underlying those vulnerabilities. Although, the drivers that cause vulnerability greatly vary from society to society, certain common factors can be listed such as resource management, efficiency, development, and sustainability. The concept of resilience needs to be understood in the context of these factors. The way resources are managed (or mismanaged) by human societies is the fundamental root cause of vulnerability. Resources are consumed indiscriminately in the name of human progress and development. Efficiency in the optimization of resource use has become the ultimate goal of human beings. The impact of decline in resource base on ecosystem services is not taken into account in this quest for optimization of resources. Walker & Salt (2006) in their classic work on Resilience thinking, calls this as “business as usual” approach, which is characterized by the absence of consciousness in human societies about valuing their ecosystems. Business as usual approach revolves around the notion that “efficient use of resources will result in sustainability.” Brian and Salt opposed this conception and argued that efficiency doesn’t result in sustainability and resilience of a system. In their words “the more one optimizes the elements of a complex system of humans and nature (social-ecological systems) for some specific goal, the more he diminishes that system’s resilience (pp. 1). This drive for efficient, optimal use of resources reduces the capacities and renders the total system vulnerable to disasters (Services such as life support, regenerative, cleansing, and aesthetic services that nature provides are collectively known as ecosystem services by Walker & Salt, 2006. Ecosystem services are crucial for the survival of human societies.).

Development is another factor that contributes to vulnerability of societies. Normatively, development is conceived as progress made by human society in

enlarging people's choices for achieving the qualities of a good life. Traditionally, these qualities were defined in terms of economic well-being, such as income, livelihood, and economic growth. Initial development models didn't consider social and political aspects such as inequalities, lack of voice and access to power and resources, etc. (Thompson, 2020). A multidimensional approach to development emerged, including economic, social, and political aspects. In this sense, development is defined as "the capacity of the systems and their processes to facilitate growth, inclusiveness and opportunities for all" (Thompson, 2020, pp. 41). The notion of development gave license to humans to exploit Mother Earth indiscriminately. "Development at any cost" became motto and the quest for development continued unabated without considering the costs of exploiting nature. Natural resources such as land, air, water, flora, and fauna are taken for granted in this developmental fiasco as if they are infinite resources. This "anthropocentric approach" toward natural resources exacerbated their degradation and increased the vulnerability of communities to disasters (Ramesh, 2010; Guha, 2014).

Sustainability and sustainable development are also related to vulnerability. Sustainability added ecological perspective to development discourse. It aims at replacing indiscriminate use of resources with responsible and judicious use of resources without disturbing developmental interests. It promised that the needs of future generations will not be compromised due to the developmental needs of current generations (Najam et al., 2006; Wingqvist et al., 2012). But in reality, sustainability and sustainable development are of little concern for most of the countries. The notion of sustainable development is misconceived in the sense that it is impossible to balance both developmental requirements and ecological concerns (Thompson, 2020). If sustainable development is condensed to the slogan of "reduce, reuse and recycle" without finding recourse to our insatiable desire for resource consumption, it would distort societal capacities to withstand disasters and increase vulnerability.

Vulnerability is also not uniform across all sections of society. Vulnerability increases as we go down the social hierarchy from affluent to poor and marginalized sections. Issues like poverty; social inequalities and exclusion; gender discrimination; disparities in health, education, and income; and lack of access to power are the drivers that render a considerable chunk of the population vulnerable to disasters. This is the major reason for dissimilar vulnerabilities within similar communities.

The above mentioned drivers such as resource management; efficiency; development; sustainability; poverty; social inequalities and exclusion; gender discrimination; disparities in health, education, and income; and lack of access to power are root causes of vulnerability to disasters. Any disaster risk reduction effort that ignores these drivers of vulnerability results in myopic goals, wrong priorities, and wastage of resources. Hence, this approach argues that we should redesign our disaster governance strategies for reducing the vulnerabilities of societies to disasters. Such an approach would automatically make communities and societies resilient.

Resilience Thinking in Disaster Governance

The questions of vulnerability and resilience are the questions of Governance. These questions are related to the capabilities of Governance in creating and maintaining sustainable social-ecological systems rather than optimizing resource consumption. The world we see today is witnessing increased vulnerabilities and reduced capacities of disaster governance. The inherent ability of social-ecological systems to adapt to changes is fast diminishing due to “thresholds” (Walker & Salt, 2006) and result in disasters. In other words, disasters are manifestations of inherent development problems. The ways we perceive vulnerability, resilience, and disasters and the models we apply to govern them are flawed (Walker & Salt, 2006; Thompson, 2020).

The year 2015 became an important milestone in the evolution of resilience thinking in disaster governance with Sendai Framework, Sustainable Development Goals, and the Paris Agreement of United Nations Framework on Climate Change. Sendai Framework (2015–2030), successor of Hyogo Framework (2005–2015) “marks a definitive shift globally towards comprehensive disaster risk management aimed at disaster risk reduction and increasing disaster resilience going far beyond disaster management” (NDMP, 2019, pp. 59–60). The Sendai Framework urges that disaster risk governance should stress on recognizing the social and environmental drivers of vulnerability and adapting measures to manage resources in a manner that leads to disaster risk reduction. The framework also emphasized on strengthening disaster governance. It urges that there should be coordination among various institutions and meaningful participation of various stakeholders in disaster governance. Sustainable Development Goals (SDGs) is another important global initiative that is linked with resilience thinking. Although SDGs are not directly related to disaster governance, the achievement of these goals (especially the goals of Climate Action) substantially provide favorable atmosphere for achieving disaster risk reduction and building resilient communities. Paris Agreement of 21st session of Conference of Parties (COP21) to United Nations Framework Convention on Climate Change (UNFCCC) adopted in 2015 ponders upon the notions of vulnerability and resilience at length. Article 7 of the agreement exclusively provided for strengthening resilience and reducing vulnerability to climate change. Specifically, the article declared that countries should work for “building the resilience of socio-economic and ecological systems through economic diversification and sustainable management of natural resources” (UN, 2015, pp. 11).

As reflected in the above mentioned major global initiatives, resilience thinking mandates national governments to restructure their disaster governance institutions, policies, and mechanisms in a manner that not only build adaptive capabilities to manage disasters but also identify and address underlying drivers of vulnerability to disasters in the long run. These initiatives also urge individual countries to integrate resilience thinking in their policy frameworks and build institutional mechanisms of disaster governance at all levels to effectively manage disasters.

Resilience Thinking in Disaster Governance of India

Resilience thinking in Disaster Governance of India reflects the paradigmatic shift from management to reduction of disaster risks by focusing on the underlying drivers of such risks. The Government of India incorporates the provisions of major global initiatives on climate change and disaster management such as the Sendai Framework and the Paris Agreement in the policy framework of disaster governance meticulously from time to time. The policy framework of disaster governance in India includes the Disaster Management Act, 2005, the National Disaster Management Policy, 2009, and the National Disaster Management Plan, 2016 (revised in 2019). The policy framework provides for institutions, regulations, and mechanisms of disaster governance at national, state, and local level.

Disaster Management Act, 2005 provides for institutional framework of disaster management at the national, state, and local level in the form of National Disaster Management Authority, State Disaster Management Authority, and District Disaster Management Authority. It also provides for institutions like the National Executive Committee, the National Institute of Disaster Management, the National Disaster Response Force, etc. With the formulation of Disaster Management Policy, 2009, there is a paradigm shift “from the erstwhile relief-centric response to a proactive prevention, mitigation and preparedness-driven approach for conserving developmental gains and to minimize loss of life, livelihood and property” (NDMP, 2009, pp. 1). The policy adopted an integrated approach to disaster management by building partnerships with various stakeholders such as local bodies, civil society, communities, businesses, and media (Gupta, 2018). Both the Disaster Management Act, 2005 and the Disaster Management Policy, 2009 talk about vulnerable communities and building capacities to address disasters but do not talk about the underlying drivers of vulnerability and ways to reduce vulnerabilities among communities.

There has been a clear cut change in the resilience thinking at policy level in India as reflected in the policy framework of disaster governance, post 2015. The National Disaster Management Plan of 2019, which is a dynamic, evolving document, brought considerable maturity in resilience thinking at the policy level. The plan reflects the philosophy of the Sendai Framework, the Sustainable Development Goals, and the United Nations Framework on Climate Change in the policy framework with regard to reducing disaster risks. It highlights the need for “enhancing coherence, reinforcement and coordination among all the major global initiatives to reduce vulnerability to hazards and enhance resilience, promoting governance systems to manage disaster risks aggravated by climate change impacts and making development resilient to various disaster risks” (pp. 66).

Vulnerability and resilience are the overarching themes throughout the National Disaster Management Plan of 2019. The plan urges governments to not only build resilience capacities of communities but also to fundamentally reexamine the aspects of resource management, development, efficiency, and sustainability. The plan

recommends for shift from indiscriminate use of resources for survival and development to judicious and sustainable use of resources. This kind of change in policy thinking is a healthy sign toward building resilient communities. The following statement from the plan aptly summarizes the resilience thinking of Disaster Governance in India. The plan says:

Climate change has increased vulnerability and reduced resilience of ecosystems globally with potentially far reaching impacts on human well-being. There is, therefore, a need to foster a greater understanding of the links between biodiversity conservation, ecosystem services, climate change and other disasters risks (NDMP, 2019, pp. 56).

The plan also admits that vulnerability doesn't impact communities uniformly. It says that economically and socially weaker sections of the society are vulnerable to disasters and within these vulnerable sections, women, children, and elderly people are more vulnerable. The coping capacities of these sections to disasters are also limited due to structural inequalities and social exclusion. Although the plan mentions about the challenges of social marginalization, social exclusion, and other inequalities as causes of dissimilar responses of similar communities to disasters in the face of vulnerability, addressing those challenges is beyond the purview of disaster governance (pp. 73). The plan is limited only to catering to different needs of different sections of society before, during, and after disasters. But Disaster Governance proponents argue that resilience means not only making resources available but also making them accessible to all sections of the society so that the impact of vulnerabilities can be lessened (Thompson, 2020; McKeown et al., 2021).

Resilience thinking that aims at judicious use of resources and long-term sustainability needs to be institutionalized. The prospects of immediate survival and development compromise long-term sustainability and endurance and fling communities into the vicissitudes of vulnerability. It is time for governments at the national and state level in India to translate this resilience thinking into action. Effective institutional framework of Disaster Governance is a fundamental pre-requisite for reducing disaster risks and building resilient communities. Countries that do not have effective institutional framework of Disaster Governance tend to fail in governing disasters. The National Disaster Management Plan, 2019 admits that it is challenging to create institutional framework at different levels of governance that integrates the disaster risk reduction goals of major global initiatives. The plan suggested two ways for creating effective institutional framework of disaster governance in India. One, building a more comprehensive resilience agenda in mutually reinforcing manner that integrates the goals of major global initiatives and two, mainstreaming resilience thinking and synchronizing it with development policies.

Mainstreaming of disaster risk reduction refers to “the incorporation of risk management and climate adaptation as an intrinsic feature of all developmental efforts” (NDMP, 2019, pp. 89). It requires all development policies, programs, and activities of governments at all levels to incorporate disaster risk reduction as an integral part, rather than having separate disaster management policies. It also requires the institutionalization of disaster risk reduction in the programs and

activities of every development agency. Sound integration of resilience thinking and disaster risk reduction with developmental priorities can enhance disaster resilience, reduce risks, and promote development. The Government of India started taking active steps to mainstream disaster risk reduction in India. NITI Aayog assumed leadership role to help governments at all levels in this process. However, these steps are largely project based and need to be scaled up to all developmental sectors and agencies (Gupta, 2018).

Conclusion

Disasters are both cause and product of development. Building community capacities is not simply resilience as capacities can be defied and neutralized by the drivers that multiply vulnerability. Resilience thinking advocates an approach that aims at building community capacities to cope with disasters in the short term and mainstreaming and integrating disaster risk reduction strategies with developmental priorities in the long term. Major global initiatives on disaster governance reflect this resilience thinking. The policy framework of disaster governance in India is also in sync with such thinking. The need of the hour is to create an institutional framework that mainstreams resilience thinking in a manner that leads to judicious resource management and sustainable development. Such an institutional framework must also recognize dissimilar capacities within similar communities due to differential nature of vulnerability, work toward addressing inequalities that cause vulnerability, and strengthen the political agency of the most vulnerable communities.

Abstract

The Covid-19 pandemic and the lockdown imposed in its wake in 2020 dealt a severe blow to the livelihood and living conditions of migrant agricultural laborers in India. As the supply chain of food grains ruptured and total immobility brought the country to a standstill, this significant labor pool was left stranded far from home, unable to fend for themselves or their kin. Living in the grim shadow of those desperate months, it is crucial to examine not only the factors culminating in the humanitarian crisis engendered by the harsh and unplanned lockdown imposed by the Indian state but also to understand the context in which these workers have historically operated as a pivotal bulwark that bolsters the Indian economy. According to the Food and Agriculture Organisation, 2020 migrant workers play a crucial role in the constituting and running of agri-food systems and value-chain systems, and invariably affect market prices across the globe. These varying modes of production and diverse farming practices tend to, in turn, affect differences in wage rates, and in patterns of interstate and interdistrict migrations, undertaken to seek employment opportunities and livelihood of different social groups. Conversely, the migrant agricultural laborers within their home states have also been adversely affected because of the unavailability

of non-farm activities. It is, thus, crucial to examine this sector-wide crisis and to seek creative ways to address the issue at the policy level, in order to ensure the creation of employment opportunities and sustainable systems that ensures the welfare of this pivotal workforce.

Introduction

The outbreak of the novel coronavirus (Covid-19) has resulted in unprecedented health as well as economic crisis globally, even as we still continue to grapple with the ever-changing nature of the virus. The impact of the pandemic has been especially brutal on the marginalized sections of society in the aftermath of the shutdown of commerce and transport across urban and rural areas. The pandemic-induced lockdown in India perpetuated a massive economic shock, halting every aspect of life. The lockdown started across the country on 24 March 2020 and is still going on in one form or another. Border closures, large-scale quarantine, and transport disruptions enforced during the lockdown resulted in acutely restricted access to food as well as to means of production and purchase. Although agricultural activities were exempted from such restrictions, the agricultural value chain also ended up facing large-scale disruptions. Agriculture and allied industries, which are central to the Indian economy, contribute nearly one sixth of the Indian National Income and provide employment opportunities to approximately 50% of the workforce (NABARD, 2020). The agricultural sector is fundamental for ensuring national food security, in addition to feeding into the growth of secondary and tertiary sectors of the economy through interlacing strands between the three-tier economic structures. However, since the lockdown, production in the agricultural sector has been under a great strain due to the shortage of agricultural labor, which in turn is bound to impact and disrupt planting, harvest, and other farming operations. The Covid-induced lockdown triggered reverse migration of laborers in northwestern agro-dominant states like Punjab, Haryana, and Uttar Pradesh (Singh, B., et al. 2020). Most of whom are predominately from marginalized social groups such as Scheduled Castes and Scheduled Tribes. In India, a sizeable portion of seasonal migrant laborers employed in agriculture and allied activities belong to historically deprived sections of society, especially among the Scheduled Castes and Scheduled Tribes.

Estimates suggest that nearly one million laborers have returned to their homes with little to no prospects of returning to geographies of employment in the near future (Chaba & Damodaran, 2020). The pandemic and the ensuing lockdown created an acute shortage in the supply of labor in agro-dominant states like Punjab, Haryana, and others, creating a vacuum that threatened the harvest and post-harvest

operations. The region-wise differences in soil quality, climatic conditions, and cropping patterns create disparity in the development of regional agricultural activities and their modes of production.

Migration and Status of Agricultural Labor

In many developing countries like India, agriculture-related migration generally traverses from low-income areas to high-income ones. The demand for agricultural labor during the peak seasons, i.e., harvest and planting, often cannot be met by the local labor pool, thus workers from low-employment areas are sought. Mishra (1952) writes that underemployment in a particular area leads to the migration of agricultural laborers to other areas, provided that these areas have optimal conditions such as large-sized landholdings, adequate irrigation facilities, and a large number of landowners from noncultivating castes who do not cultivate their land themselves.

Migration has long been ingrained into the livelihood cycle of economically depressed classes across India. It is now recognized that migrating for work is a part of routine livelihood strategy for the underprivileged sections of society and does not only happen in times of distress or emergency (Mc Dowell & De Haan, 1997). Among the different categories of migrant workers in India, seasonal workers employed in agriculture and related activities who undertake rural-to-rural interstate and interdistrict migration belong predominantly to Scheduled Castes (SC) and Scheduled Tribes (ST) categories; their historically distressing socioeconomic conditions render these workers among the most deprived sections in the rural hierarchy. According to the National Sample Survey (2007–2008), 35% of ST males migrating to other states were involved in the agriculture and related activities; among the SC, this figure was estimated to be 23%, while other caste groups recorded 13% males migrating seasonally as agricultural laborers. When nationwide mobility was brought to a grinding halt in March 2020, it was this section that faced the major brunt of the unplanned lockdown. The 100 million-strong migrant workers, who are estimated to form 20% of India's workforce, were the worst sufferers of all – they were stranded in their places of work without food, wages, and shelter (Economic Survey, 2016–2017). Images of thousands upon thousands of workers trudging on roads and highways to reach home truly visualized this marginalized population to the public for the first time.

The migration of agricultural laborers occurs both seasonally and permanently, depending on the availability of work in a given area, which is directly related to the prosperity of the region. Skilled agricultural laborers tend to migrate from poor regions to prosperous ones, a process which is often encouraged by their relatives and village peoples, who are themselves seasoned migrants to these regions. This organic network acts as the centripetal force that accelerates the rate of migration (Gupta, 1988; Gupta & Bhakoo, 1980). Such migrant laborers constitute the foundation of the workforce in the northwestern states, particularly Punjab, Haryana, and Uttar Pradesh, which are considered the “breadbaskets” of the country. Punjab and Haryana contribute nearly 50% of the staple food grains that are procured and

distributed by the Government of India; production deficits in these states due to the shortage of agro-labor have a huge impact on national food security (Chauhan et al., 2012; DFPD, 2015). Acute labor shortages in farming activities in a state is bound to impact the plantation of labor-intensive crops like rice/paddy, which is sown in a narrow temporal window in the month of July. The dependency on migrant labor for such seasonal, intensive, and physically demanding work escalates during the rice (*kharif* or monsoon season) and wheat (*rabi* or winter season) plantation time. Punjab alone requires 50-million-person days for planting monsoon crops, particularly rice (Dhillon & Vatta, 2020). Punjab and Haryana contribute 65% of the total wheat and 34% of the total rice in food stocks, which are then procured by the Food Corporation of India and other procurement agencies. Thus, any adverse impact on the production of agricultural produce in these states significantly impacts national food security, inducing fear and paranoia. The phenomenon of reverse migration and scarcity of labor induced by the pandemic has become a leading factor in exacerbating the present-day agricultural crisis in India.

Agricultural wage rates in states with high demand and low supply of laborers have increased while wages in states that saw an influx of migrant laborers saw a steep decline due to surplus of labor. However, in the aftermath of the pandemic, the dynamics of supply and demand in rural areas show a mixed trend due to the outflux of laborers from agriculturally advanced regions to their influx into relatively backwards regions. Even before the pandemic, the socioeconomic conditions of agricultural migrant laborers were far from ideal, as they had to work long hours with minimum wages. Generally, though, food and shelter were provided by the landlord throughout the period of stay during the working season in farming lands. Landlords, too, preferred migrant laborers to local ones because;

- a) They could haggle over wages with migrant laborers to crank up their own profits.
- b) Reduce the risk of laborers switching over to other farmers during the working season, which local workers often tended to do. Oftentimes, personal rapport, long-running interactions and fair economic exchanges induced migrant laborers to work for the same farmers year after year. The main interest for the migrant laborers was the promise of receiving a lump sum to take back home at the end of each cycle (Roglay et al., 2001).

Most workers engaged in the agricultural industry are vulnerable groups of daily wagers who earn just enough to sustain themselves for short periods of time. They have no income security in case of job loss, due to which they are unable to cope with any form of recession. In the initial phase of the March 2020 lockdown, when 21 days' cessation of all forms of activity and travel was enforced, hordes of workers descended upon bus and railway stations, desperate to leave for their native states. The central government was forced to rethink the travel restrictions and to make special arrangements when millions took to the roads and highways, walking thousands of kilometers to reach the safety of their homes. Not only were these journeys arduous, they often resulted in death for those undertaking them, and in heartbreak for those watching them on television screens in the comfort of their

homes. These desperate caravans, seen for the very first time since the Partition, spotlighted the utter misery of this otherwise invisible sector of migrant workers, who constitute the foundation of the national workforce.

Covid-19 and Rural Economy

Covid-19 and the ensuing economic devastation threatened to turn into a humanitarian crisis in the face of the mass exodus of migrant workers back to their villages. Moreover, this reverse migration has put a lot more pressure on the already challenged and ailing rural economy. The pandemic has taken a massive toll on communities and geographies of origin, as the perpetually under-resourced local government bodies are now faced with the daunting task of accommodating, providing, and meeting the socioeconomic needs of the returnees. Most of these migrant workers are landless or hold only a small piece of land, which acutely hampers their chances of building a robust agricultural practice in their native region (Kukreti, 2020).

Lamentably, the pandemic came at a time when the already-embattled Indian economy was facing a steady economic slowdown. The complete lack of policy/policies for the welfare of such a large chunk of the workforce is very concerning, to say the least, and its utmost urgency is the need of the hour. In the wake of the lockdown, the All India Agricultural Workers Union (AIAWU), which has the highest membership of agricultural laborers in India, has put forward its demands to address the deteriorating conditions of farm laborers. The union is now pressing the government to provide food and shelter to the out-of-work populace, especially as now these workers are unable to afford even basic necessities. AIAWU is also demanding that the government must replenish funds for schemes like MGNREGA, which has been neglected over the years; the union has pointed out that the mandate of the scheme, which guarantees hundred days of employment to all rural household under the Rural Employment Guarantee Act, 2005, must be made available to potential beneficiaries.

The agricultural sector cushions the national economy and needs to be foregrounded at the level of policy-making and its execution, especially after the disastrous impact of the lockdown on the Indian economy. The sector still holds the promise of employing thousands who have lost their means of livelihood due to the pandemic-engendered crisis, alongside the tremendous responsibility of feeding the entire population of the country. NABARD's Impact Assessment report for the year 2020 stated that the total agricultural area sown under all the major *kharif* crops was expected to yield higher than the corresponding period of 2019. Quite remarkably, things did turn out this way. As per the above report, the impact of the 2020 lockdown was low-key on crop production because the major crops of the *rabi* season, like wheat, mustard, gram, and the like, were harvested in most states by the end of April 2020 (NABARD, 2020). This respite was possible due to the fact that the agricultural sector was largely exempted from the major restrictions imposed during the initial phase of the lockdown, as mentioned earlier.

By all accounts, MGNREGA did help in providing wage-based employment to some of the returning migrant workers by rolling out projects in rural areas to absorb the additional labor force (Narayani, 2020). However, many of the migrant workers who returned to their villages during the lockdown may still wish to remain there. Therefore, their immediate needs for food, shelter, and the provision of temporary employment opportunities in their native places must be addressed at the policy level. States like UP, Bihar, Uttarakhand, Chhattisgarh, and Jharkhand saw a large influx of migrant workers during the lockdown. The lockdown restrictions have led to a drying up of jobs and incomes, and so, there is an urgent need to reorient national as well as regional migration policies in such a way that they aid the process of providing assistance and protection to the migrants arriving in their native place from distant geographies of work. Resilient food systems need to be established and activated through adequate funding to curtail food insecurities so that the renewed pressure on local systems created by the arrival of the returning populace can be reduced too. Migrant workers, especially agricultural workers, form the backbone of the Indian economy; sadly, they are also among the most vulnerable groups in India. Their needs and grievances deserve serious attention and creative policy solutions.

The International Labour Organization (ILO), 2015 provides a framework for Decent Work Agenda that can help in curtailing the adverse impact of Covid-19 on the national workforce. The primary focus areas of the Decent Work Agenda are as follows: job creation, rights at work, social protection, and social dialogue with gender equality. Target 8.8 of ILO's Sustainable Development Goals (SDGs) 2030 also aims to "protect labour rights and provide safe and secure working environments for all workers, including migrant workers, in particular, woman migrants and those in precarious employment."

Challenges of Migrant Laborer

The challenges and problems faced by the migrant labor workforce during the lockdown necessitate the urgency for the universalization of the Decent Work Agenda of ILO. As things stand, there are very few safety nets for this labor pool and so, the state needs to intervene on multiple fronts to ensure the welfare of those being dispossessed of their health and livelihood. In the National Sample Survey Office report (2007–2008), it was revealed that temporary labor migration within India is seven times higher than permanent migration and that in the poorest households (those of Scheduled Castes and Scheduled Tribes), temporary migration is up to sixteen times higher than permanent migration. In the destination regions, migrants help sustain many industries and sectors, and without the migrant workforce, many industries would not be able to survive in the face of the sheer shortage of local labor skilled in the said work. These workers have historically been underpaid and overworked, owing to which sustaining themselves beyond a short period is impossible for this exploited section; the pandemic-engendered lockdown

only highlighted the glaring lack of safety net for these workers and the complete absence of safe channels of migration. Migrant workers are unrecognized at the local, regional, and national levels, and are therefore often overlooked at the official policy level itself. Due to the sudden shutdown of secondary and tertiary sectors during Covid, employability, income, food security, shelter, etc., were critical. The plight of migrant workers and their distressing experiences during the lockdown evidence the contrariness of their lived reality to the egalitarian principles enshrined in the constitution. India's labor protection framework fails to adequately address the challenges faced by the informal sector workforce, who constantly move around to varied destinations in search of work. They are at the risk of further marginalization, exclusion, and being invisible if the very frameworks that can prevent the violation of their rights (like labor codes) are not implemented effectively. It has been seen that the implementation of policies such as Pradhan Mantri Shram Yogi Maan-Dhan or other health benefits schemes for unorganized workers state or local governments exclude the migrant laborers who come from other states and do not have the domicile of the current state. However, some states like Kerala have welfare policies for migrant workers named the Awas scheme, Interstate Migrant Workers Welfare Scheme, and the Apna Ghar Hostel Scheme. There is an urgent need for a major revamp and strengthening of regulatory institutions and justice delivery architecture to assist in the survival and healthy living conditions of workers.

Today, India faces multidimensional problems that must be addressed to ameliorate the plight of migrant laborers. The informality of India's economy, along with rigidly layered social structures and poor working conditions, has all come to be intricately woven together to create an impassable wall that this workforce is unable to scale. Therefore, it is now the onus of policymakers to conceptualize policies keeping in mind the multiple facets of the labor conundrum; such policies must be holistic in their definition and implementation, or else they will fall shamefully short of addressing the demands of the changes needed.

The first step to prevent the further worsening of migrant workers' situation is to reorient the question of informality and the divisions that characterize India's labor markets. Limited employment opportunities in the formal sector of the Indian economy compel a vast majority of workers to seek employment in the informal economy, especially among migrants. The government of India has attempted to tackle this problem by trying to gather the much-needed data on the migratory workforce through the recently established National Database (Nanda, 2020). The goal is to register unorganized laborers and migrant workers and subsequently facilitate employment and better access to welfare benefits. Moreover, the lack of access to medical insurance and portability of ration cards pending for years and decades was an important game-changer. Additionally, the announcement of Skill Development plans seems to have laid the groundwork for an exhaustive initiative that will target the returning migrant workers in 116 districts across the country (Shukla, 2020). The idea behind these initiatives is to allow workers to access work based on their existing skills and also re-skilling and upskilling them to correspond to the needs of the current job market.

Policy Implications

The said trend highlights most of the workers migrating from rural areas to urban areas for better employment apart from other reasons such as natural disasters. It has become the usual practice of small and marginal farmers or laborers who do not have land and has to work on daily wages on the agricultural land of the others. Here they did not get a handsome amount and get only fewer job opportunities due to the neglected attitude of the government toward rural development. Migrant workers who moved to urban areas have to suffer in their day-to-day living due to the high market rates, especially for three basic things, food, shelter, and clothes (Rogaly & Thieme, 2012). They are marginalized to avail of the so-called living standards of elites; even they have to live in ghettos and under the flyovers, which do not have access to electricity, clean water, and safe house.

Moreover, recently the Covid-19 pandemic made the life of migrants in India miserable. During the lockdown, India had its largest exodus since independence, with over ten million people trekking thousands of kilometers to rural areas, the reverse migration due to no jobs, rising conditions of famine for them, and fears of getting affected by the virus (Suresh et al., 2020). Many of them died not by the virus but on the journey to reach home by foot. As a result, the labor force participation rate dropped from 42.9% in January 2020 to 35.57% in April. In April, unemployment rose to 23.52%, with both rural and urban areas feeling the pinch (Yadav & Priya, 2021). Further, citing the problems faced by the migrants and criticism faced by the people, the government in the name of NITI Aayog drafted a policy named National Migrant Labour Policy. Earlier the Indian government resolved in December 2020 to build a database of migrant workers, including those in the informal economy. This policy wanted to overcome the previous policies, for example, the Interstate Migrant Workers Act, 1979, which only caters to the laborers who migrated through contractors without including independent migrants. This policy acknowledges the migration of labor as an integral part of the nation's development. It has also recommended increasing wages and preparing a central database to fill the gap between demand and supply for the utilization of maximum benefit of social welfare schemes and to build migration resource centers. However, this policy does not go into the underlying causes of inadequate labor law execution, which are tied to the political economics of recruitment and placement. The document makes a passing mention of unfair recruitment practices, but there is no examination of why the system exists and how it is allowed by company and enterprise employment structures. It makes no mention of gender disparities in the workplace. Thus, we can say that migrant laborers are still a vulnerable group of society by being marginalized by government help and a high standard of living.

Conclusion

Covid-19 not only brought into focus the dangerously precarious plight of migrant labors but also foregrounded their immense contribution to the development of the nation and its economy. The need of the hour is to strengthen the rural economy

through creative planning, financial investments, and sustained ministration so that labor migration to agro-dominant states in search of work opportunities can be transformed into an informed, safe, and sustainable process that further strengthens the foundations of the Indian economy. The aim should be to reduce distress migration and promote safe migration, a kind of migration that is propelled by significantly improved working conditions and fair wages. The amelioration of the migrant agricultural worker is possibly one of the first steps needed to strengthen the promising agricultural sector to ensure that this symbiosis continues unabated.

From time immemorial, India has been an agriculture-centered economy, its rich land made even more fertile by the blood and sweat of its agricultural workers. Even at this moment in our country's history, when the economy was almost brought down to its knees by the aftereffects of the novel coronavirus pandemic and the crippling lockdown that ensued, it was the agricultural sector that became the life buoy that kept the Indian economy afloat. Despite suffering devastating personal crises and losses, the agricultural workforce has aided immensely in the nation's gradual but steady resurgence. As a nation, we owe it to the tillers of the soil to ensure that their interests are protected, just as they have always protected ours.

Abstract

Climate-related hazards are phenomena that demand all governments to be at all times on high alert. Governments should undertake measures that would eliminate or at least mitigate their impact to protect their constituents. This study

utilized three researcher-made data gathering tools. Results revealed that the tasks of the Barangay (Village) Disaster Risk Reduction and Management Committees (BDRRMCs) in the river basin communities on disaster prevention and mitigation were partially accomplished. As a whole, the performance of the BDRRMCs is generally satisfactory (3.65). This is broken down into formation of structures and systems (satisfactory = 3.62) and institutionalization of policies and plans (satisfactory = 3.65).

The findings further revealed the highly significant impact of the following BDRRMC performances: Punong Barangays' (Heads of Villages) educational attainment and years in the service and the community's experience in floods. The FGD responses indicated that the TRB barangays have major issues and concerns considering the implementation of DRR tasks: putting up of the DRRM structures and systems, communication, commitment of the Barangay officers, and limited budget. There is a cogent need for all government offices handling the DRRM functions to provide appropriate attention at the Barangay level for the proper implementation of the DRRM Plan.

Community · Disaster prevention · Mitigation · Climate-related hazards

Background of the Study

From 1900 to 2014, 136 floods and 314 storms hit the Philippines, inundated communities, claimed lives, lost billions, and crippled the economy. In 2011, tropical storm (TS) *Sendong* (international name, *Washi*) devastated *Misamis Oriental*'s major city of *Cagayan de Oro* and several communities in the two river systems, i.e., the *Tagoloan River Basin* (TRB) and *Cagayan de Oro River Basin* (CDORB), including the coastal towns under the *Macajalar Bay Development Alliance* (MBDA) from *Laguindingan* to *Kinoguitan*. Though not as strong as *Sendong*, another TS *Vinta* (aka *Timben*) entered PAR 4 days before Christmas of 2017 and claimed 75 lives in Region 10, and because of flash floods coming from headwaters upland, about 200 families evacuated to *Sta. Cruz* and *Natumolan*, both in *Tagoloan, Misamis Oriental* (*Citizens' Disaster Response Center, 2017*).

The study focuses on the Barangays (Villages) in the Tagoloan River Basin (TRB). The basin is the thirteenth (13th) largest river system in the Philippines and has a total area of about 180 thousand hectares of waterways, plateaus, canyons, and valleys which starts from the province of *Bukidnon* covering five (5) municipalities and one (1) city, then down to *Misamis Oriental*'s three (3) municipalities or a total of 26 barangays, and finally discharges an annual run-off of 4106 MCM onto *Macajalar Bay* through its main drainage – *Tagoloan River* (Regional Development Council, 2005). Most (57%) of TRB is forest, while the remaining proportion is disposable land (Regional Development Council, 2005).

Disaster prevention and mitigation is everyone's concern. Threat to safety and security is the new norm faced by the LGUs. In same breadth, climate-related hazards, especially in the villages within the area of the Tagoloan River Basin, are now part of the realities of life. Stoker (1998) contends that the local governments have expanded increasingly their authority in the dispensation of local services. Governance perspective sees an increased involvement of the private and voluntary sectors in service delivery and strategic decision-making. Responsibilities that were previously the near exclusive role of government have been shared (Stoker, 1998). Because of this, Local Government now draws attention to private sector to be part of the solution to the problems besetting the community while increasing the machinery of the LGU.

Section 2 of RA 10121 amplifies the policy of the State on disaster risk reduction and management. It spells out the aspirations of the Republic to uphold the people's constitutional right to life and property by addressing the root causes of vulnerabilities to disasters. Among other directions being set by this law is to strengthen the capacities of the LGUs and communities in disaster prevention and mitigation from the impact of disasters. In declaring the State policy on DRR Management, it recognizes that the State could not achieve its purpose without decentralizing the powers, responsibilities, and roles at the regional and local levels. Section 5 of the Implementing Rules and Regulations of RA 10121 states that the Barangay leaders shall ensure the participation of at least two (2) Civil Society Organization (CSO) representatives from existing and active community-based people's organizations representing the most vulnerable and the marginalized groups in the Barangay DRRMC.

One of the four priority areas of the Barangay Disaster Risk Reduction and Management Committee is on disaster prevention and mitigation, the first pillar of the DRRM program. Disaster prevention and mitigation refers to the activities that would avert or lessen/limit the occurrence of adverse effects of hazards. This would cover the role of the BDRRMCs on the formation of DRR structures and systems (organizing of BDRRMC, adoption of BDRRM Plan, Evacuation Plan, etc.) and institutionalization of policies and plans (ensure the BDRRMC structure is complete with personnel, establishment of emergency hotlines, and others).

To ensure clarity of the roles of the Local Governments in disaster risk reduction and management, Joint Memorandum Circular No. 2013-01 of the National Disaster Risk Reduction and Management Council, Department of Interior and Local Government, and Department of Budget and Management was issued to define and enumerate the particular functional/priority areas of the DRR program that can be funded by the Barangay's 5% DRRM budget. Based on this order, only the given tasks in the four DRR priority areas the 5% DRRM budget can be utilized and released. The same priority areas in disaster risk reduction and management program in disaster prevention and mitigation of the BDRRMC are utilized as the main indicators of the study in order to consider, review, and assess on the performance of the Barangay Disaster Risk Reduction and Management Committee, particularly on its first priority area in disaster prevention and mitigation.

Objectives of the Study

The objective of the study is to review, assess, and determine the performance of the BDRRMCs in the Tagoloan River Basin Barangays based on the instructed tasks on disaster prevention and mitigation outlined by the National Disaster Risk Reduction and Management Council for the smallest Local Government Units (Barangays) to implement at their respective communities. Hence, Fig. 1 shows the relationship of the variables of the study vis-à-vis the mandated DRRM tasks, specifically on disaster prevention and mitigation and the characteristics of the TRB barangays and the immediate past Punong Barangays and the three climate-related hazards. The dependent variable is the level of performance of the Barangay Disaster Risk Reduction and Management Committees on disaster prevention and mitigation on the following Barangay DRRM framework: (a) formation of structures and systems and (b) institutionalization of policies and plans. The level of BDRRMC's performance refers to the rating of the Barangay leaders of the relevant actions and activities initiated and other roles and responsibilities carried out by the BDRRM committees in pursuing its mandated functions on disaster prevention and mitigation considering the existing guidelines of the implementing rules and regulations of RA 10121.

The study sought to determine the level of performance of the Barangays in the river basin communities as regards the level of compliance on the mandates issued by the higher authorities on disaster prevention and mitigation. As the forefront in the disaster risk reduction management of the government, these Barangays were charged with the formation of structures and systems and institutionalization of policies and plans in their respective jurisdictions. The particular functions of the

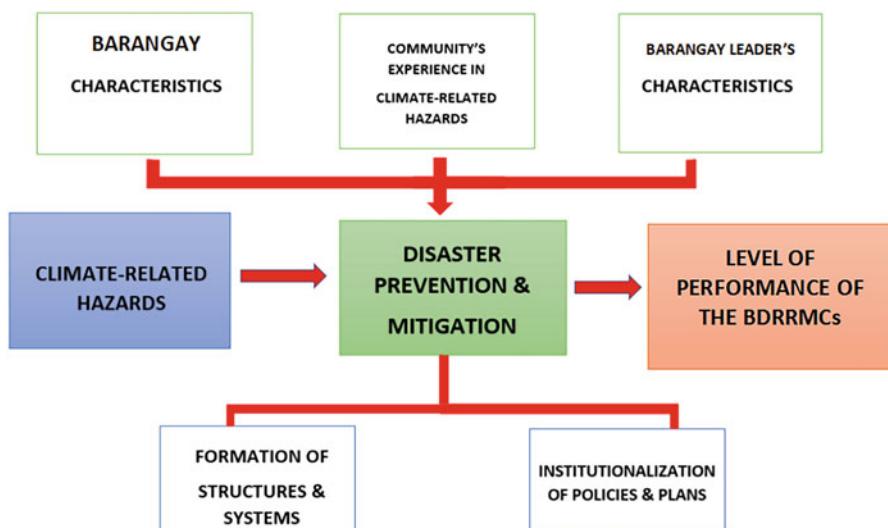

Fig. 1 Schematic diagram showing the relationship of the variables of the study

BDRRMCs on disaster prevention and mitigation were assessed on the respondents' ratings of the performance of the BDRRMCs. Barangay characteristics are limited only to the populations and the budgets of the TRB barangays as these would help explain in the variations of the variables in the performance of the BDRMCs. Furthermore, community's experience in climate-related hazards (CRHs) was assessed to test the level of performance of the BDRRMCs since the DRRM framework in the government was established to ensure that appropriate preventive measures of the LGUs would be in place to protect the citizens from and to mitigate the disastrous effects of climate-related hazards. Accordingly, the three climate-related hazards (floods, heavy rainfall, and unseasonal/erratic rain) are the natural hazards that frequented the most in the TRB communities which were also considered to form part in the study. Punong Barangays' characteristics (educational attainment, age, gender, and years in the service) were also considered to check which of these independent variables explain the variations in the performance of the BDRRMCs.

The results of the study would benefit the stakeholders in understanding as to which of the variables would explain a better performing BDRRMC. Pointedly, these variables would provide clearer explanations on the variations in the performance of BDRRMCs in the villages of the Tagoloan River Basin.

More specifically, the following questions were sought for answers to determine the level of performance of the BDRRMCs, considering disaster prevention and mitigation:

1. What is the level of performance of the BDRRMCs considering disaster prevention and mitigation?
2. To what extent do the independent variables explain the variations in the level of performance of the BDRRMCs?
3. What are the issues and concerns that surfaced in relation to the level of performance of the BDRRMCs considering disaster prevention and mitigation?

Related Literature

Disaster Prevention and Mitigation and Recent Advances

According to the United Nations International Strategy for Disaster Reduction (2018), between 1998 and 2017, climate disasters accounted for 91% of all 7255 recorded disasters in the whole world. Among them, floods were the most frequent, at 43% (Wallemacq & House, 2018). Therefore, if there are no substantial measures, climate disasters will bring about serious damages to people's mobility and life resulting in economic losses.

In recent years, influenced by climate change and human activities, natural disasters have become more frequent, causing increasingly great losses (IPCC, 2014). One important task of government with regard to disaster prevention and mitigation is to reduce damage loss and guarantee people's livelihood through fiscal

expenditure. For this reason, the appropriate proportion of government's fiscal expenditure on disaster prevention and mitigation has become a difficult issue of public concern (Sawada & Takasaki, 2017). If the proportion is too low, it is not conducive to implement disaster-preventing and mitigating measures; if the proportion is too high, it will crowd out other investment expenditures, which does not contribute to the sustainable development of economy and the continuity of government's disaster reduction work (Benalia et al., 2016).

To be an effective and responsive local government unit, it must be directed by competent officials. In the case of the Barangay Government, it must be constituted with capable Barangay officials who could handle the management of a village effectively, such as planning and fiscal administration (DILG-LGA, Guide for Punong Barangays/Barangay Leaders, 2018).

Research Methodology

Research Design

This study used the descriptive research design. It involves the descriptions and evaluation of the existing conditions related to the performance of the Barangay Disaster Risk Reduction and Management Committees in the Barangays of the Tagoloan River Basin on disaster prevention and mitigation. According to Best and Kahn (2006), this design allows some type of comparison, contrast, and uncovering of relationships between existing non-manipulated variables in the study.

Statistical Tools

The findings, analysis, and interpretation of the data gathered, the following statistical tools, were employed:

Frequency, percentages, mean, and standard deviation. These were used to answer the objectives 1 and 2.

T test and F test. These tests were used to determine significant differences in the level of performance of the BDRRMC considering the independent variable of the study.

Multiple Linear Regression Analysis (MLRA) and MLRA with dummy variable.

These techniques were used to determine the extent to which the independent variables explain the variations in the level of performance of the BDRRMC. All the MLRAs in this study met the assumption on multicollinearity of the independent variables, indicating that these variables are not collinear.

Research Environment

The study covers the eight local government units within the Tagoloan River Basin. Three are municipalities within Misamis Oriental Province located downstream of

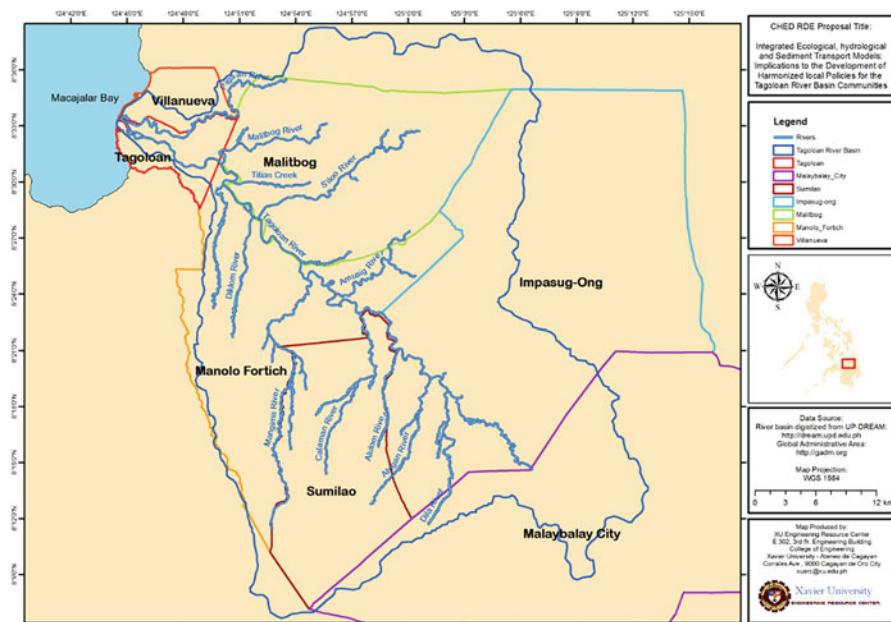

Fig. 2 Map showing the municipalities included in the study

the basin, while five belong to the Bukidnon Province, upstream of the Tagoloan River Basin; both provinces are situated in Southern Philippines. A total of 152 respondents are from 26 Barangays (Villages), constituting the 8 municipalities. The main rivers of TRB are the following: Tagoloan River, Malitbog River, Siloo River, Titian River, Mangima River, Alulum river, Amusig River, and Dila River as shown in Fig. 2.

This study utilizes Cochran's formula in the determination of the sample size, where $\alpha = 0.05$, $Z = 1.96$, and a margin of error $E = 0.103$. The sample size, $n = 152$, was allocated to the different barangays where the barangay council members and other members of the BDRRMCs from the private sector were chosen randomly and the Punong Barangays, the Secretaries, and the Treasurers comprised the remaining respondents.

Respondents and Data Gathering

The 152 respondents of the 26 Barangays in this study were chosen randomly. Each one was given the question form. These were duly filled out during the scheduled data gathering per batch of respondents supervised directly by the researcher and trained staff. Two focused group discussions (FGDs) were also conducted for selected respondents to address objective 3. The FGD results also triangulated the quantitative findings of the study.

Summary of Findings

What Is the Level of Performance of the BDRRMCs Considering Disaster Prevention and Mitigation?

Table 1 presents the ratings of the respondents on the level of performance of BDRRMCs considering *disaster prevention and mitigation*. More than 50% of the respondents rated their barangays to have a very satisfactory to excellent BDRRMC, 25% gave a satisfactory rating, while 22.37% rated their BDRRMC from very low to low level. In general, the level of performance of the BDRRMCs, considering disaster prevention and mitigation, in the TRB barangays is at the satisfactory level (3.65).

As shown in Table 1, some sub-indicators for the level of performance of the BDRRMCs on Creation of Structures and Collation of Barangay Data were rated as generally accomplished (82–98%) to indicate the level of performance of the BDRRMC. These are the following: *Barangay Emergency Response Team (BERT) creation* (82.24%), *information on Risk Assessment of the barangay* (82.29%), *baseline data on number of houses* (86.18%), *Barangay Risk Map Data* (92.11%), and the exceptionally attained task that was on creation of BDRRM Committee (98.03%).

However, majority of the indicators for the creation of BDRRMC structures and collation of barangay data were considered by only 42–56% of the respondents to have been accomplished as indicator of the level of performance of the BDRRMC. These are on the following sub-indicators: *baseline data on value of houses in the barangay* (49.34%), *value of properties* (42.11%), *livestock* (50%), *crops* (55.26%) in the barangay, *accomplishment of Barangay Disaster Readiness Checklist* (55.92%), and *maintained and updated databases (including directory of key offices)* (56.58). Low level performance of the TRB barangays in terms of these sub-indicators may be indicative of the limited resources and lack of technical expertise of the people running the affairs of the barangay. Valuation of houses and properties requires technical knowledge as to how to appraise and make appropriate assessment. Collation and updating of barangay database need trained

Table 1 Level of performance of the BDRRMCs considering disaster prevention and mitigation

Level of performance	Frequency	Percent (%)
Excellent (4.60–5.00)	36	23.68
Very satisfactory (3.70–4.59)	44	28.95
Satisfactory (2.80–3.69)	38	25.00

personnel. Shah et al. (2019) pointed out that human resources, in general, and expert and trained personnel, in particular, play a crucial role during and after the disaster. They reported that institutions in disaster-prone areas lack staff available for Disaster Risk Reduction.

On the additional functions of the Punong Barangay, the indicators of the level of performance of the BDRRMC, considering *disaster prevention and mitigation*, present a very satisfactory level. These are reflected in the percent of respondents who considered its sub-indicators to have been accomplished, namely: *Installation of Barangay Risk Map in conspicuous places (55.92%)*, *designated a Public Information Officer (PIO) (50.66%)*, *appointed at least 2 CSO representatives to the BDRRMC (63.16%)*, *designated a dedicated officer to man the operation center (63.82%)*, and *displayed disaster-related signages, markers in strategic locations (63.16%)*. Only one sub-indicator was rated by the respondents as generally accomplished, namely: *ensured the inclusion of VDRRM Plan in the Annual Investment Program (AIP) (85.53%)*.

As to the establishment of Disaster Risk Reduction Management System, the respondents rated this indicator at the satisfactory level of performance of the BDRRMC. Majority of the sub-indicators for establishment of DRRM System were considered to have existed in their barangays by the respondents (55–78%) as indicators of the level of performance of the BDRRMC. These are the following: *Incident Command System (ICS) (55.26%)*, *24/7 functional Operation Center System (58.55%)*, *establishment of an Early Warning System (75%)*, and *development of a System of Family/Community Preparedness and Response Measure (78.29%)*. Only one sub-indicator was rated by the respondents as generally accomplished, namely: *Annual Budgeting System of the Barangay duly complied with at least 5% allocated for the BDRRM Fund (88.16%)*.

As regards the institutionalization of policies and plans, a component of the disaster prevention and mitigation, which is at the satisfactory level, respondents considered some sub-indicators to be present in their barangays. Majority of the sub-indicators for BDRRMC functions on DRR Policies and Plans also exist in the TRB barangays, according to 46–78% of the respondents indicating some level of accomplishment of the BDRRMC. These are on the following: *Barangay Climate Change Action Plan (40.13%)*, *quarterly conducted drills to test the Contingency Plan (46.05%)*, *ensured the participation of the members of the community on the drills conducted (53.29%)*, *contingency plan per hazard (66.45%)*, *Emergency Hotlines and Communication Plan (69.74%)*, *BDRRMC Staffing Complement (73.68%)*, and *Evacuation Map (78.29%)*. These sub-indicators are connected to capacitate those who are engaged or implemented preparedness plan and those who are responsible for carrying rescue and relief operation (Nazli, et al., 2014). Crafting a plan for climate change, contingency plan per hazard, and communication plan require deeper knowledge on the effects of the environment degradation and the surrounding issues.

Indicators	% Mean	Desc
A. Formation of Structures and Systems	3.62	Sat
A1. Creation of BDRRMC Structures & Collation of Barangay Data	3.54	Sat
Punong Barangay had issued orders for the creation of the following:		
1. BDRRM Committee	98.03	
2. Barangay Emergency Response Team (BERT) creation	82.24	
3. Information on Risk Assessment of the Barangay	82.29	
4. Baseline data on number of houses	86.18	
5. Baseline data on value of houses in the barangay	49.34	
6. Baseline data on value of properties in the barangay	42.11	
7. Baseline data on livestock in the barangay	50.00	
8. Baseline data on crops	55.26	
9. Accomplishment of Barangay Disaster Readiness Checklist	55.92	
10. Barangay Risk Map data	92.11	
11. Maintained and updated databases, including directory of key offices	56.58	
A2. Additional Functions of the Punong Barangays in DRRM	3.74	Very Sat
PB has assigned DRRMC functional personnel and installed appropriate BDRR markers:		
1. Appointed at least 2 CSO Representatives to the BDRRMC	63.16	
2. Designated a dedicated officer to man the Operation Center	63.82	
3. Designated a Public Information Officer (PIO)	50.66	
4. Ensured the inclusion of BDRRM Plan in the Annual Investment Program (AIP)	85.53	
5. Installation of Barangay Risk Map in conspicuous places	55.92	
6. Displayed disaster-related signages, markers, and directional signs in Strategic locations	63.16	
A3. Establishment of Disaster Risk Reduction Management System	3.59	Sat
Barangay Leader had issued order for the following:		
1. Incident Command System (ICS)	55.26	
2. Establishment of an Early Warning System	75.00	
3. 24/7 functional Operation Center System	58.55	
4. Annual Budgeting System of the Barangay duly complied with at least 5% allocated for the BDRRM Fund and 30% of which was segregated for the Quick Response Fund	88.16	
5. Developed a system of family/community preparedness and response measure	78.29	
B. Institutionalization of Policies and Plans	3.65	Sat
B1. BDRRMC Functions on DRR Policies & Plans	3.53	Sat
The BDRRMC had adopted the following Disaster-Related Policies & Plans:		
1. BDRRM Plan	87.50	
2. Barangay Climate Change Action Plan	40.13	
3. Contingency Plan per Hazard	66.45	
4. Evacuation Map	78.29	
5. Emergency hotlines and Communication Plan	69.74	
6. Quarterly conducted drills to test the Contingency Plan	46.05	

(continued)

7. Ensured the participation of the members of the community on the drills conducted	53.29	
8. The BDRRM Committee ensured the enforcement of a policy that the Committee has complete functional personnel with corresponding tasks and functions	73.68	
B2. BDRRMC Functions on IEC	3.84	Very Sat
BDRRMC had acted on the following:		
1. Disseminated to the public, families and individual advisories, bulletins, flyers and other IECs with basic information on different hazards bulletins, flyers and other IECs with basic information on different hazards	86.18	
2. Published & disseminated emergency hotlines	69.74	
3. Barangay-wide information campaign on the Emergency Balde	50.66	
4. Coordinated with LDRRMO for the release of weather advisories and emergency bulletins	76.97	

Furthermore, only one sub-indicator was rated by the respondents as generally in placed, namely: BDRRM Plan (87.50%). This indicates a higher level of performance of the BDRRMC on this aspect. Kusumasari (2012) argued that the local government plays an essential role in introducing, managing, and implementing different disaster management initiatives. The core in disaster risk reduction effort is having to craft a BDRRM Plan and design an Evacuation Map as part of the disaster prevention and mitigation measures.

Table 1 also shows the BDRRMC functions on IEC at a very satisfactory level (3.84). These can be attributed to the existence of the following sub-indicators in the TRB barangays, as indicated by the respondents: disseminated to the public, families, and individual advisories, bulletins, flyers, and other IECs with basic information on different hazards (86.18%) and coordinated with LDRRMO for the release of weather advisories and emergency bulletins (76.97%). In these aspects, the BDRRMC is functional. However, only 50.66% of the respondents specified that the barangay-wide campaign on the Emergency “Blade” was in place. This finding does not conform to the government mandate on the massive campaign for disaster preparedness, such as flood. This is perhaps due to the general topography of the TRB barangays which are mountainous, and the households are at some distances from each other contributing to the difficulty of a barangay-wide campaign. This also requires inspection of the presence or absence of the emergency “blade” in every household, to monitor the effectiveness of this barangay-wide campaign.

On the other sub-indicator, 69.74% of the respondents specified that publishing and disseminating emergency hotlines was present in their barangays. The data imply that, to some extent, these practices/guidelines exist in the TRB barangays, which is an indication of the BDRRMC performance. As the barangays are located in a river basin, these practices/guidelines are expected to have been fully in place. With the rapid improvement of technology, messaging and information dissemination are more attainable even in remote areas. Stewart and Rashid (2011) and Nakamura et al. (2017) argued that use and access to information and comprehension

of instruments designed to support decision-making, both at the institutional levels and the individual/household, can help in risk management.

To What Extent Do the Independent Variables Explain the Variations in the Level of Performance of the BDRRMCs?

Table 2 shows the results of the initial and final Multiple Linear Regression Analysis (MLRA) between the dependent variables and the three set of independent variables (barangay characteristics, characteristics of immediate past PBs, and the community's experience in climate-related hazards). The null hypothesis stating that the independent variable does not explain the variation in the dependent variable is rejected ($F = 16.33^{**}$). The final model $\hat{y} = 0.52 + 0.49X_1 + 0.04X_4 + 0.02X_6$ is highly significant. The variables in the model, PB's educational attainment and years in the service, and community's experience in floods explain 23% of the variation of the level of performance of the BDRRMC in disaster prevention and mitigation. In fact, for every increase in the educational attainment of the Punong Barangays in the TRB barangays, the level of performance of the BDRRMC in disaster prevention and mitigation increases by 0.49 holding PB's years in the service and community's experience in floods constant. Similarly, for every year increase in the PB's years in the service, the level of performance of the BDRRMC in disaster prevention and mitigation increases by 0.04 holding PB's educational attainment and community's experience in floods constant. Furthermore, for a unit increase in community's experience in floods, the level of performance of the BDRRMC in disaster

^dsignificant ($0.05 < \alpha < 0.10$)

prevention and mitigation increases by 0.01 holding PB's educational attainment and years in the service constant.

The findings imply that the level of performance of the BDRRMCs in disaster prevention and mitigation is explained by the PB's educational attainment, years in the service, and the community's experience in floods. The BDRRMC's tasks in disaster prevention and mitigation would require PB's understanding of some technical and administrative functions, such as formation of BDRRMC structures and systems, establishment, and institutionalization of DRR policies. The facilitation of these functions becomes more efficient for Punong Barangays with higher educational attainment. Haslam et al. (2005) explained that effective education provides high level knowledge to individuals which enable them to analyze different situations and respond accordingly.

Moreover, the PB's years in the service also contribute significantly to the BDRRMC's performance considering disaster prevention and mitigation. PBs with more years in the service are more exposed to the work and functions of the smallest local government office. This type of exposure would lead them to find better options to carry out the disaster prevention and mitigation function resulting to a more performing BDRRMC. Similarly, the community's experience in floods explains significantly the BDRRMC's performance in its disaster prevention and mitigation role. Barangays with more experience in floods are more likely to prepare for a similar future occurrence and generate more cooperation from the constituents for a better disaster prevention and mitigation program and activities. The community's experience in floods, such as personal experience when it comes to presence or absence of preparation in flooding situations, can be an effective tool.

Furthermore, these results on the level of performance of the BDRRMCs considering disaster prevention and mitigation have clearly proved that when these attributes are present of a Punong Barangay and the community, better BDRRMC service is expected. Experience, both personal and communal, in the barangay office in a flood-prone area (river basin), can provide an impactful direction of the BDRRMC's performance on disaster prevention and mitigation. Similarly, PB's educational attainment distinctly explains the BDRRMC's performance as PB with higher education has an advantage in having better understanding in the basic skills in administrative work. Matyas and Pelling (2015) point out that organizational resilience implies learning and therefore not returning to the previous position.

What Are the Issues and Concerns that Surfaced in Relation to the Level of Performance of the BDRRMCs Considering Disaster Prevention and Mitigation?

The FGD responses reveal that to certain extent, some of the TRB barangays have formed the BDRRM structures and systems and institutionalization of policies and plans of the DRRM framework. However, issues and concerns were aplenty considering implementation. Generally, these are in the absence of putting up of the DRRM structures and systems, communication system aspect (including IEC), and

commitment of the Barangay officials to DRRM functions, and the most common is the very limited budget for DRRM.

Conclusion

As a whole, the performance of the BDRRMCs in the TRB barangays, considering *disaster prevention and mitigation*, is generally satisfactory. This is broken down into formation of structures and systems (satisfactory) and institutionalization of policies and plans (satisfactory). The findings clearly show the need for the river basin communities to improve the level of performance of the BDRRMCs, particularly on disaster prevention and mitigation. The results are indicative of a common problem persisting in the barangays where there is deficiency in administrative skills, particularly in setting up and strengthening the BDRRMC policies, systems, and structures. The laws and administrative orders may be present; however, issues on how to effectively put every intention of these mandates into actions still remain to be fully seen. There is an apparent gap between the law (RA 10121) and the capacity and the effectiveness of the Barangay leaders to comply with and enforce the law. Further, there is a cogent need for all government offices handling the DRRM functions to provide appropriate attention at the Barangay level for the proper implementation of the DRRM Plan.

Furthermore, the results of the study point to the highly significant impact of the following on the level of performance of the BDRRMCs: Punong Barangay's educational attainment and years in the service and the community's experience in floods. The latter would develop higher consciousness on the negative effects of climate-related hazards, which can be an effective tool in advancing a much improved barangay's disaster prevention and mitigation measures. The facilitation of the BDRRMC functions, such as the formation of the BDRRMC structures and systems, establishment, and institutionalization of DRR policies, is better for communities that have Punong Barangays with higher educational attainment and longer years of experience and longer community experiences in floods.

The FGD responses indicated that the TRB communities have major issues and concerns considering the implementation of DRR tasks, such as putting up of the DRRM structures and systems, communication system aspect (between higher LGUs & barangays), and commitment of the barangay officers to DRRM functions. These results validate the earlier conclusion that the BDRRMCs were just performing fairly in complying the mandates of the law and DRR guidelines.

Moreover, the BDRRMCs were deficient in their tasks, particularly in ensuring the participation of the community, which can include private individuals and organizations on the conduct of drills, appointing representatives from Civil Society Organization to the BDRRMC, involving the community in adopting the family guide on disaster preparedness, coordinating with other institutions or organizations for additional equipment during disasters, and enlisting volunteers. These functions are articulations of a policy that the role of the BDRRMC can no longer be done by the LGU alone but by institutional arrangements with the private sectors as partners

in finding solution to the threats posed by climate-related hazards. As theorized by Stoker (1988), governance refers to a set of institutions and factors that are drawn from, but also beyond, governance. Responsibilities that were previously the near exclusive role of government are better off to be shared. As an enabler in establishing the DRR structures and systems, the BDRRMC has in its authority to increase the membership of the Committee to include key individuals or organizations for the furtherance of the intentions of RA 7160 and RA 10121.

Recommendation

River basin communities should have higher standards and rules in disaster risk reduction and management, considering various hazards that frequent this place. At least, if residents are allowed to reside and own lands in flood-prone areas, the government should institutionalize the rules of engagement in preparing and protecting the public from ill effects of climate-related hazards. Entrusting the Barangays with higher responsibilities in disaster prevention and mitigation should come with full complement of support in terms of strengthening their capacities and needed infrastructure and resources. Corollary to this, it should also strictly implement the administrative obligations on the LGU officers through imposing accountability.

To the Future Researchers

Conduct a study on the implementation of RA 10121, focusing on the operational relationship between the involved government agencies and the local government units, whether the existing DRRM framework is compliant to and is effectively enforced pursuant to the PDRRM law and its implementing rules and regulations. Determine also the effectiveness and functionality of the local DRR and Management Councils.

This study is not without *limitations*. It is the level of performance of the DRRM Committees in the Barangays of the Tagoloan River Basin that was looked into. This was limited to the first task of the BDRRMCs in disaster prevention and mitigation. Moreover, considering climate-related hazards are wide in scope, in this study, only floods, heavy rainfall, and unseasonal/erratic rain were considered. The respondents were those who have direct knowledge on the affairs of the Barangay DRRM Committees. The higher LGUs (municipalities/cities/provinces) were not included in this study since the management of the DRRM 5% fund is the exclusive domain of the barangay governments based on the existing laws. The same laws vest distinct authority to the barangays on the management of the DRRM Committees. Hence, the study is limited only to the TRB BDRRMCs.

Acknowledgments The principal author of this study expresses his gratitude to the support of Xavier-Ateneo de Cagayan University for choosing this author to benefit in terms of the direction of

this study and the funds provided by the XU-CCHED Research Project, especially in the data gathering phase. The principal author also expresses his thanks and gratitude to Ester L. Raagas, PhD, for her professional guidance and direction that caused the completion of this chapter and to the XU-CCHED Research Project leader, Astrid L. Cinco, PhD, for her useful comments on an earlier version of the chapter.

Conflict of Interest The authors report no relationships that could be construed as a conflict of interest.

Abstract

India being a disaster-prone country is affected by various disasters every year. The unplanned urbanization and environmental degradation have led to climate change, which in turn has led to the rapid increase in extreme natural response thus increasing our vulnerability to different disasters. Among these disasters, flood is one of the deadliest and destructive natural disasters that India faces. The recurrence of floods differs geographically as some places are more prone than

e-mail: shuaib@manuu.edu.in

the rest. Kerala is one of the disaster-prone states of India. This south-western state received 42% excess rainfall than the normal from 1 June to 19 August 2018 causing widespread floods across the state. The floods and landslides created havoc all across the state leading to the loss of 445 lives and large-scale destruction to infrastructure, socioeconomic sector, and to the environment. The 2018 Kerala flood was the worst one in nearly a century. It shook the core of the people's confidence in the ecological foundations. The havoc caused by the 2018 Kerala flood was not only the result of unprecedented downpour but there were other reasons also which turned it more disastrous. To decrease the brunt of any disaster we have a systematic approach of disaster risk reduction (DRR), where after identifying and assessing the risk we take adequate measures to reduce the risk of a disaster.

Disaster · Vulnerability · Unplanned Urbanization · Floods and Disaster Risk Reduction

Introduction

Disasters being as old as human civilizations have become part of our lives (Parsa & Zehra, 2020). Since ages disasters are creating havoc and sufferings for mankind. Now with the increase in risk drivers like poverty, inequality, rapid unplanned urbanization, environmental degradation, weak governance, and climate change, the frequency of these disasters have increased many folds in past 20 years. In the year 2020 and 2021, a total number of 430 and 401 natural disasters took place, respectively, across the globe (Jaganmohan, Global number of natural disasters events 2007–2021, 2022b). The fatalities recorded in these 2 years were 15,071 and 10,000, respectively (Jaganmohan, Global number of deaths from natural disasters 2007–2021, 2022a). The India floods were the deadliest disaster in 2019 with 1750 fatalities (Department, 2020). In the year 2020 India lost around 87 billion dollars to climate disasters (Nandi, 2021).

With the increase in vulnerability the ratio of people living in flood-prone areas is going up at a rapid scale. With rapid urbanization and climate change this number could annually increase up to 54 million (Global flood toll to rise by 2030, 2015). It is estimated that by 2050 this population will reach up to 1.3 billion, which is equal to the 15% of the world's population. This figure indicates an increase of 0.3 billion over the present and it counts both coastal as well as river flooding (Willem Ligvoet, 2014). The World Resources Institute 2015 reports that annually the river flooding affects 21 million people across the globe.

Kerala, which is popularly called as the “Gods own country” is a land rich in natural resources. It is a narrow land belt in the south-western border of the Indian Peninsula. The Western Ghats surround the state from the east and the Arabian Sea from the west. From physiographic point of view the state of Kerala can be

categorized in to three zones, viz., the lowlands, which comprises of coastal areas where the elevation is from below the sea level up to 8 m. The second one is the midland, where most of the plantation and agricultural activities are carried out. These midlands are located at an altitude between 8 m and 75 m above mean sea level (amsl). The third zone is the highland in which forests come. The elevations in such zones go up to 2700 m amsl (Kumar, 2018).

The state of Kerala is vulnerable to various hazards and is classified as a multiple-hazard-prone state. The unique geographic location, high density population, and weather pattern makes Kerala prone to many severe natural and human-induced disasters.

The state experiences various types of recurrent disasters, which lead to the loss of lives, destruction of environment, damage to property, loss of livelihood, and disruption of economic activities ((KSDMA), n.d.). The Kerala State Disaster Management Plan (KSDMP) points out 39 types of hazards that have the potential to cause disaster.

Among various hazards, Kerala is more prone to flooding, which affect people, environment, infrastructure, and economic activities as shown in the Fig. 1. With the increase in risk drivers, the state faces recurring riverine floods (Kerala State Disaster Management Authority, 2016).

The state of Kerala is a land of rivers and rains with two main seasons of rain; “Edavapathi,” which is the Southwest monsoon and arrives either at the end of May or during the initial days of June and the other one is the Northeast monsoon also called as “Thulam,” which hits the State in mid-October. Annually, the heavy monsoon rains are part of the State but in 2018 the Southwest monsoon had a different and devastating impact as it produced a disastrous flood (State Relief Commissioner, 2018).

Annually, the State of Kerala receives an average rain of about 3000 mm and almost 90% of this rain occurs during the 6 months of monsoon period. From 1 June to 18 August 2018, Kerala received unprecedented rainfall, which resulted in severe flooding. The expected downpour from 1 June to 19 August was 1695.5 mm but as per the Indian Meteorological Department (IMD) data, Kerala received 2346.6 mm amount of rain for the same period. The amount of rainfall that the state received was about 42% higher than the normal average. But what turned it more disastrous was its skewed distribution; during the month of August the downpour went up by 164% from the normal, which resulted in the inundation of 13 out of 14 districts with 7 of them (Wayanad, Thrissur, Pathanamthitta, Kottayam, Idukki, Ernakulam, and Alappuzha) severely affected ((GOI), 2018). The intense and excessive rains occurred during 1–20 August. During this time the state received about 771 mm amount of rainfall. This caused various landslides and forced the discharge of surplus water from 37 dams throughout the state, thus worsening the flood impact. There were around 341 landslide incidents recorded from 10 districts, and the district of Idukki was the worst hit by 143 landslides (Bank, 2018). These disastrous floods and landslides caused colossal damage to the state by destroying houses, bridges, roads, power supplies, and other infrastructure.

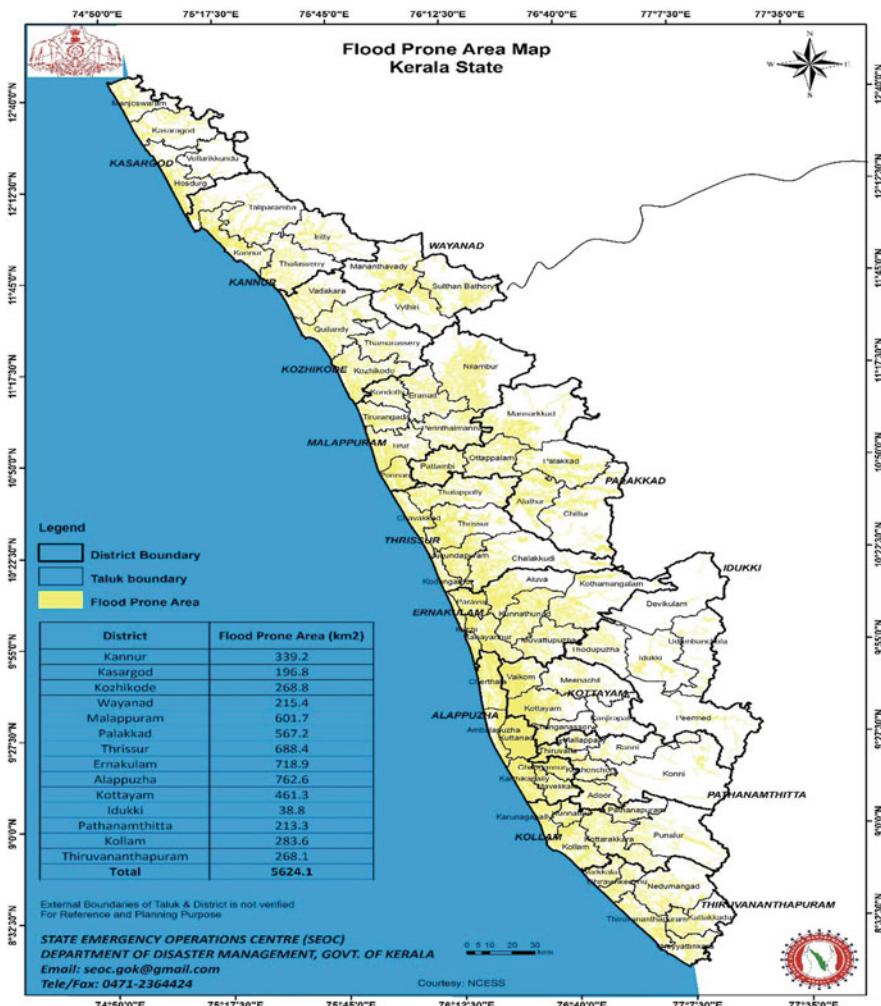

Fig. 1 Flood prone areas. Source (KSDMA)

The 2018 floods created havoc across the state of Kerala leaving behind large-scale devastation and destruction. It was the worst ever flood in the history of Kerala since 1924 flood. This devastating flood was listed among the five major extreme flooding events in the world between 2015 and 2019 by the World Meteorological Department. The flood affected the entire rural area of the state, which comprises 52.30% and a population of around 33.5 million. There were 339 lives lost and large-scale destruction was reported to infrastructure and environment. The Cochin International Airport, one of the busiest airports of India, also got inundated, which led to the suspension of its operations for 15 days from 15 to 29 of August 2018 (State Relief Commissioner, 2018).

Table 1 Losses incurred by different sectors

S.No.	Sector	Loss incurred (Millions)
1	Housing, land, and settlements	54,430
2	Health and nutrition	6,000
3	Education and child protection	2,140
4	Agriculture, fisheries, and livestock	44,4980
5	Water, sanitation, and hygiene	13,310
6	Transportation	1,00,460
7	Electricity	3,530
8	Other infra facilities	24,460
9	Environment	1,480
10	Irrigation	14,830
11	Employment and livelihood	38,960
12	Disaster mitigation	1,100
13	Gender and social inclusion	350
14	Local governance	320
15	Integrated water resource management	240
16	Culture and heritage	800
Total		3,07,390

Source (Express T. N., [2018](#))

The disastrous floods and massive landslides induced large-scale damage to infrastructure like houses, railways, bridges, roads, electricity, and communications networks. Crops and livestock got washed away, which had a severe impact on both the livelihood and lives of tens of thousands across the state. According to a report of need assessment (PDNA), which was jointly prepared by a development program of UN (UNDP) and the Kerala administration, the state suffered a massive loss of around INR 3,07,390 million ([World Bank, 2018](#)). An estimate shows that Kerala lost around 2.6% of gross state domestic product (GSDP) to floods. The administration at the central level announced it as a Level III Calamity ([Rai, 2019](#)). Losses in different sectors which the state suffered are shown in Table 1.

Disaster Risk Reduction

Disaster risk reduction is the practice of mitigating risk associated with various disasters by systematically analyzing and minimizing the causal factors. It focuses on preventing future disaster risk, reducing the existing risk, and managing residual risk. This helps to increase resilience and to achieve the goal of sustainable development. Some prominent examples of disaster risk reduction are: reducing the vulnerability of people, minimizing the exposure to various hazards, proper land management, adequate and effective preparedness, etc. ((UNISDR, [n.d.](#))).

In this regard, the Sendai Framework for Disaster Risk Reduction 2015–2030, which came after the Hyogo Framework for Action (HFA) 2005–2015, was the first

significant agreement, which offers Member States with concrete actions to preserve development benefits from disaster risk.

Following the 2015 third United Nations World Conference on Disaster Risk Reduction, the United Nations General Assembly adopted the Sendai Framework for Disaster Risk Reduction 2015–2030 (UNDRR, [n.d.](#)). This framework provides a setup to reduce the risks associated with disasters. To prevent new disasters and minimize the existing risk from disasters, the Sendai Framework for DRR has outlined seven global targets and four priorities for action.

The following are the four priorities of action that provide a way for reducing the risk associated with disaster.:.

- (i) Understanding the risk associated with disaster
- (ii) Managing the disaster risk by building disaster risk governance
- (iii) Creating disaster resilience by investing in disaster reduction
- (iv) Building preparedness for adequate response and to “Build Back Better” in terms of recovery, reconstruction, and rehabilitation ([Nations, 2015](#))

When we study about the risk reduction measures adopted by the state of Kerala, we find that the government had not taken up the priorities set by the Sendai Framework seriously. Various lapses on the part of administration were noticed in the management of the 2018 floods. The measures of disaster preparedness and response taken by the Government of Kerala were insufficient and inadequate. The various constraints found in the management of 2018 floods are discussed in the following:

Inadequate Flood Management Provisions in Planning

In 1987, the Government of India’s issued a National Water Policy (NWP), which was amended in 2002 and again in 2012. Flood management was contemplated and incorporated in the NWP. To reduce the loss of life and property due to floods, the NWP 2002 proposed the states to come up with a Master Plan for managing and controlling of floods in flood-prone basins, including proper flood cushions, and stringent rules of settlements and commercial activity in floodplain zones.

The State Water Policy (SWP), which was drafted by the Water Resources Department in July 2008, does not take into account the issue of flood management in the state. The provisions in the Government of India’s Water Policy that emphasized flood preparedness, upgradation of flood forecasting system by adopting real-time data acquisition related to forecasting models, evolving reservoir operating procedures for flood cushion, and expanding the preparedness level for unforeseen and unanticipated floods were not incorporated in the State Water Policy of Kerala. In the report of the Comptroller and Auditor General of India titled “Preparedness and Response to 2018 Floods in Kerala,” some serious issues like lack of laws for floodplain demarcation, water body and wet land encroachments, the lack of flood forecasting stations, and insufficient desiltation actions were discovered. Flood

controlling methods were not included in the State Water Policy, indicating that flood management issues were accorded a low priority (Shaji, 2021).

Lack of Master Plan for the Management and Control of Water Resources

Micro watershed was regarded the basic unit in the State Water Policy (SWP) 2008, and the river basin was deemed an integrated unit of micro watersheds. In the 2008 State Water Policy, micro watershed was deemed as the primary component and the river basin an integrated component of micro watersheds. It intended formation of a master plan at the state level for managing and developing water resources by action plans in each micro watershed, sub-basin, and river basin in a hierarchical way. In addition, master plans for the state's major rivers were to be produced, which would serve as the foundation for any river-based initiative. A State Level River Authority was also to be established to coordinate all river basin-related operations. The State Level River Management Authority is yet to be established, and its absence meant that there was no institutional structure in place to ensure coordination between different implementing agencies and to monitor the prioritization of projects. The master plan has been completed for only one river, the Chaliyar, as well as two of the five tributaries of the Bharathapuzha river. As a result, the master plans for 42 of the 44 rivers have yet to be created, despite the fact that they are included in the State Water Policy. Lack of master plans for the state's major rivers means that work regarding flood control functions on an ad hoc basis (CAG, 2021).

Failure of the State in Bringing Legislation for Identifying and Demarcating Floodplains

Floodplain zoning methods focus on identifying and demarcating the places that are likely to be affected by the floods. It also identifies the sort of developments that are permitted in these zones so that in case of floods, the damage is minimized if not evaded.

For flood plain zoning legislation, the Government of India published a model draft for all the states in 1975. This model suggested creating a Flood Zoning Authority, surveying floodplains and prohibiting or restricting the use of such areas. Regarding the flood management, there is a guideline from the National Disaster Management Authority, which talks about the regulation of floodplain zoning (Express T. I., 2022). But unfortunately, the state of Kerala has yet to establish the legislation regarding floodplain zoning. Furthermore, the state's floodplains have not been demarcated (The Hindu, 2021). Legislation with regard to identifying and demarcating floodplain zones would have allowed the government to take preventative actions against anticipated encroachment in floodplains, which could have proved very helpful for the state government in flood management efforts.

Flood Hazard Map Not Complying with the Standard

Flood Hazard Mapping is an important tool, which helps in identifying areas that are at the risk of flooding and also assists in prioritizing the measures of mitigation and response. Kerala had a flood-prone area of 14.52% of its total land area. Despite this, there was no large-scale flood hazard map in the state (Shaji, 2021). In June 2013, the Government of India expert committee for scientific assessment of flood prone areas in the country classified those flood-affected locations that have a 10-year return period as “flood prone areas.” This committee suggested every state to form a regional committee, which apart from other things would be in charge of identifying flood prone areas of the state using the methodology developed by them. So, in September 2016, the State Government of Kerala drafted a Disaster Management Plan for the state but the map selected by the state administration for this plan was generated long back in the year 2010 on 1:50,000 scale using satellite imagery by the National Centre for Earth Science Studies (NCESS). Despite the fact that the expert committee in 2013 established the flood return period (10 years) as the yardstick for identifying an area as flood prone, yet the state administration continued to bank on the map generated in 2010 by NCESS, which does not stick to the criteria laid down by the expert committee; thus the state lacks the large-scale flood hazard map.

Dearth of Rain Gauges and Flood Forecasting

Rain gauges are tools that meteorologists and hydrologists use to collect and measure the amount of liquid precipitation that falls over a specific area over a specific time period. Rainfall measurement at various key places is necessary due to considerable spatial variability of rainfall. The location of rain gauges in an area with high spatial variability in rainfall is very important for accuracy in rainfall estimation. Therefore, the density of rain gauges is critical in determining how much rain falls in a given area.

A study was conducted by the Indian Institute of Science (IISc) Bangalore on 2018 Kerala floods with target as the Periyar River Basin, one of the largest river basins of the Kerala state, which covers a distance of 5400 km². The study noticed that the Indian Metrological Department had suggested a minimum requirement of 32 rain gauges for rainfall estimation in this area but only 6 gauges were available (Express T. I., 2022). The dearth of rain gauges resulted in lack of real-time data on spatially disturbed rainfall, which caused a detrimental impact on forecasting.

Flood forecasting encompasses level forecasts and inflow forecasting. When the water level in a river reaches a pre-determined alert level, level forecasts are issued (which normally is 1 m lower than the danger level but also banks on the risk perception of a specific area). The level forecasts assist user agencies in determining mitigation measures such as evacuation and the relocation of people with their mobile property to safer places. Inflow forecasting is utilized by different reservoir

and dam agencies in ensuring optimal reservoir operations for risk-free management of flood downstream as well as to ensure that reservoirs have enough capacity to meet demand during non-monsoon period.

In 2021, an audit report prepared by the Comptroller and Auditor General of India on Preparedness and Response to 2018 Floods in Kerala noted that in 2011 the Central Water Commission (CWC) had asked the administration of Kerala to provide the list of populated towns and reservoirs that require flood forecasting and inflow forecasting stations, respectively. But the state administration did not provide the required information, so despite the fact that by 2017 CWC had established 275 flood forecasting stations across the country, none of these stations were established in the State of Kerala (Express, The New Indian, 2021). This failure of the state administration resulted in non-installation of flood forecasting systems in the state, which led to loss of the data that the administration could have used for effective flood forecasting.

The unavailability of adequate flood forecasting system led to inaccurate predictions in the state. The heaviest spells of rain that caused the greatest floods in the state of Kerala took place from 8 to 17 August. The contrast of rain forecast and the actual rain received is shown in Table 2.

The table distinctly shows that the downpour received by Kerala was absolutely unprecedented. Although heavy to very heavy rainfall was predicted for most districts on 8 August, the prediction limit exceeded too far, and torrential rains lashed Idukki and Wayanad. Although on 8 August there was a heavy to very heavy rainfall prediction in maximum districts, the prediction limit surpassed too much and heavy rains of severe nature lashed Idukki and Wayanad. On 9 August 2018, while there wasn't any serious alert requiring actions, the rainfall was of category red and orange (heavy to very heavy) in seven districts (Idukki, Wayanad, Kozhikode, Malappuram, Palakkad, Kottayam, and Pathanamthitta). Likewise on the 10th, 11th, and 12th of the same month, while red alert was issued for five to eight districts only very light to light rainfall was received.

On 15 August, which was the most pivotal day for Kerala, a forecast predominantly for yellow was issued in the State with only four districts to fall in category red and one district in orange, but the entire state had extremely heavy downpour with 18 districts falling in the red category. On 16 August 2018, prediction was issued that seven districts were receiving red and seven oranges, but the actual rain was yellow in three districts, one orange district, one green, and nine red districts. Therefore, the rains received by Kerala were much more than the predicted rains in critical days, which led to floods in the state. When comparing the daily district-wise rainfall prediction with the actual rains, a huge disproportion is witnessed.

This unanticipated and very high intensity of downpour led to severe overland flow causing the saturation of top layer of the soil, heavy landslides, wreckage flows, and erosion. This situation forced the rivers to exceed the levee areas and cause wide-scale destruction and loss of lives and property (State Relief Commissioner, 2018).

Table 2 District wise forecast and real analogy

Districts	Day-to-day rain forecast (24 h earlier forecast for each day)												
	8-8-2018	9-8-2018	10-8	11-8	12-8	13-8	14-8	15-8	16-8	17-8	18-8	19-8	20-8

Note: Rain forecast announced daily at 13:00 h was treated as the forecast for next day (The 14 Aug 2018 adjusted rain prediction received at 2000 h was treated as the forecast for 15 Aug 2018)

Dam/Reservoir Management

Majority of the big reservoirs in the state were filled with almost 90% of their capacity on 8 August. It shows that in any case, it was essential to make releases from reservoirs. Kerala has many reservoir storages and even before flooding (8 August) the level of many of these reservoirs was very high. The storage level of seven major reservoirs, i.e., Periyar, Parambikulam, Malampuzha, Kakki, Kallada Idamalayar, and Idukki was higher than it should have been.

On 8 August 2018 six (out of seven) dams were brimmed up to 90% of their full reservoir level (FRL). Parambikulam had reservoir storage of 99.5% to its FRL while in Malampuzha, Idukki, Kallada, Kakki, and Idamalayar, the storage on the same day was 97.8, 92.5, 97.3, and 90.5% of their FRL. Periyar was the only major reservoir in the state with a storage level of below 80% of its FRL. Surplus (40–50%) rains took place from the month of May to August, which resulted in high storage of water.

Heavy and extreme rainfall after 8 August lead to the shortage of reservoir capacity to contain the additional increased flow forcing the discharge of a considerable volume of water in a short period of time. On 9 August 2018 after issuing the red alert, the gates of reservoir Idukki were thrown open to discharge water. This blending of excessive rain and water release from reservoir aggravated the floods in the state (Vimal Mishra, 2018).

The CAG report of 2017 has castigated deficient emergency action plans (EAPs) and other reservoir operating manuals. The report points out that the dams miss the “rule curves.” Rule curve is the level of water in a dam that can be retained safely. Each dam is likely to have a particular rule curve, which, besides other things, instructs the filling of a dam in the monsoon season that improves flood controlling and moderation for downstream areas. Most of the dams in the state were nearly brimming by July end, which is an outright contravention of rule curve, as the month of July is the midway of Edavapathi or Southwest Monsoon. This filling up of reservoirs by July end was an open call for flood calamity (Rai, 2019).

Moreover, in response to an RTI query, the CWC disclosed that not a single dam in the entire state of Kerala was checked ahead of the monsoon arrival. It also mentions that only two dams were inspected prior to monsoon in the year 2015, four in 2016, and 2017 while the post-monsoon inspection was carried for two dams in 2015, five dams in 2016, four dams in 2017 and 2018, respectively (Kuttappan, 2018).

Sand and Stone Quarrying, Construction Activities, and Deforestation

On 31 August 2011 an expert panel of Western Ghats Ecology Expert Panel (WGEEP) led by Madhav Gadgil gave a report about the Western Ghats fragility to Ministry of Environment Forest and Climate Change (MoEF&CC). This report had suggested to categorize the 140,000 square kilometer area of the Western Ghats

within three zones; Ecologically most sensitive zones (ESZ1), in which many places will fall in “no-go” like special habitats, water bodies, sacred groves, and areas rich in biodiversity; the second category will be of ecologically more sensitive zones (ESZ2), in which futuristic development of major roads and railway tracks shall not be permitted, with the exception of being essentially required; and ecologically sensitive zones (ESZ3), in which construction of infrastructure and new developmental projects may be allowed but with “strict ecological regulations” (Rai, 2019). The report had warned that illegal mining, stone quarrying, construction activities, and deforestation had promoted huge encroachment of rivers and other water bodies in the state and had called for urgent corrective measures but all such warnings were overlooked. As a result of deforestation and infrastructural expansion, construction activities have become rampant and unplanned, resulting in slope modification, excavations, and quarries (Sangomla, 2018). These activities were devastating in terms of natural slope destabilization induced by the elimination of vegetative cover, which led to landslides. During the floods of 2018, these slopes were washed away at various places, resulting in a large sediment flux in the rivers. Apart from increasing slope instability, many structures downstream, such as roads and bridges, interrupted the natural course and reduced the width of various rivers by acting as a “barrier” to water and sediment movement. This led to “drainage congestion,” as there was not sufficient space to allow flood waters to pass safely. This aggravation of channels with sediments exacerbated the flood situation by inundating the nearby areas.

Another report known as “Kasturi Rangan Committee report” classified 37%, which comprises of almost 60,000 km² of Western Ghats, as ecologically sensitive and for its notification the suggestions were passed to the environment ministry. It was only in the year 2017 that the said ministry declared 57,000 km² of this area as ecologically sensitive. In this area all ventures related to mining, high polluting industries, and vast constructions were banned. This act opened up a large part of this sensitive area to various ventures like mining and constructing reservoirs/dams, etc. (Staff, 2018).

Latest research carried by the KFRI shows that there are around 5,924 quarry units across the Kerala. Another report published by Global Forest Watch said that the state of Kerala has had large-scale forest disappearance in recent years. Kerala lost forest land of 7,187, 9,722, and 6,237 hectares in the year of 2016, 2017, and 2018, respectively (Sen, 2020). All these factors added more risk to the hazard prone state of Kerala and turned 2018 floods more devastating.

Encroachment of River Space

Kerala, like many other parts of the country, has suffered major encroachment of river space due to uncontrolled and ill-planned urbanization, which has progressively converted the lush and permeable floodplains into human settlements. This has not only restricted floodwater infiltration for groundwater recharging and excess rainfall accommodation, but it has also put a significant population and infrastructure at risk.

The Kerala Nadhi Samrakahsna Samithi discovered considerable encroachment on the Chaliyar River, with the encroachers largely being businesspeople. The encroachment has occurred in the municipalities of Feroke and Ramanattukara, as well as the villages of Olavanna and Pantheeramkavu in Kozhikode and Vazhayur in Malappuram (SR, 2019).

In the Alappuzha district, the Uttarapalliyar River has also been significantly encroached upon. The Kerala high court has intervened in this matter, stating that the river has been encroached upon on a large scale, resulting in significant river constriction (Sharma, 2018). River Periyar, which is known as the lifeline of Ernakulam, has also been encroached at various stretches due to the misgovernance of authorities. During the last few years, around 200 residential complexes have sprung along the river bank. Due to the inaction of the government around 25 acres of encroachment have been observed along the Perumbavoor-Aluva section alone (Sunil Kumar M. K., 2011).

The president of Confederation of Real Estate Developers Association of India (CREDAI) Mr. Antony Kunnel says that the River Management Fund in Ernakulam alone had over Rs 100 crore in the year 2010. Despite no shortage of funds, the authorities ignored the request to survey and demarcate the river boundaries. According to the Coastal Regulation Zone (CRZ) Act, any structure must have a 100-meter setback from the river. However, this regulation has been violated time and again due to the callous approach of the government (Sunil Kumar M. K., 2011).

Shrinking Wetlands

The state of Kerala is widely known for its wetlands. These wetlands not only grant livelihood to thousands of residents in the forms of agricultural produce, fiber, fish, fuel, and fodder but also act as a sponge in flooding conditions. But these wetlands are diminishing very rapidly. Large-scale reclamation, encroachment, deforestation, and pollution are causing wetlands to shrink. In 2004, there was around 328,402 ha of wetlands in Kerala, which was reduced to around 160,590 ha in 2015 (Preetha and Laladhas 2017). A study by Kerala State Council for Science, Technology and Environment revealed that around 50% of wetlands and paddy fields in Thrissur district have been reclaimed in the last 30 years. As per this study, in the year 1970 there were 734.32 km² of wetlands in the district that have been reduced to just 381.29 km² now (Chronicle, 2017). Similarly, in Thiruvananthapuram the area of wetlands was around 2261.726 in the year 1965, which was reduced to just 724.42 in the year 2019 (Aiswarya Philip, 2018).

All these lapses show that the administration of Kerala is seriously lacking in disaster risk governance and needs immediate measures to manage and mitigate the risk. The administration has to act according to the priorities set by the Sendai Framework for disaster risk reduction with more focus on disaster risk governance. Not only should there be policies and legislation for risk reduction but also proper mechanism and coordination between various institutions involved in this. Adequate measures should also be taken for effectively involving community in risk reduction measures.

Approaches to Reduce Flood Vulnerability at River Basin

To reduce the flood vulnerability at river basins, the key component is to know the behavior of such floods. It is the fundamental element in identifying solutions to reduce the impact of these floods. Floods may be caused by both internal and external sources within the river basin. There are various factors that force floods at river basins as shown in Fig. 2.

River floods occur when the river channel's conveyance capacity is insufficient for the flow that must pass. In these scenarios, flood waters seek a passage over land. The flow could pass through urban areas, industrial areas, agricultural land and others. Such a flow can be quite harmful, especially if it occurs unexpectedly. The speed with which a flood hits has a significant impact on the amount of damage it causes. Flash floods, which are commonly described as floods that come within 6 h of the start of a driving factor such as heavy rainfall, are the most dangerous in terms

Fig. 2 Flood drivers at river basin. Source (Verwey Adri, 2017)

of human lives. Even in developed countries with a high level of flood protection, flash floods can cause fatalities.

Methods to Reduce Flood Vulnerability

Flooding risk can be addressed in various ways by taking a proactive approach that incorporates both nonstructural and structural solutions. Flood risk is comprised of three contributing factors: exposure, hazard, and vulnerability.

$$\text{Hazard} \times \text{Exposure} \times \text{Vulnerability} = \text{Flood Risk}$$

As we can see that the risk of flooding can be lowered by reducing the hazard, exposure, and/or vulnerability. Any hazard may be reduced largely through structural measures, whereas exposure and vulnerability can be modified primarily through nonstructural methods. Figure 3 shows various methods by which flood vulnerability can be reduced.

Structural and Nonstructural Measures

Flood risk can be reduced in different ways by using a proactive approach that combines structural and nonstructural interventions. The aim of structural and nonstructural flood measures is to reduce flood risk and it can be done through mitigating hazard, vulnerability, and exposure. The most effective way to reduce hazard is through structural measures while the primary way to change exposure and vulnerability is through nonstructural measures. Over the last few years, both structural and nonstructural methods have acquired a lot of recognition for being flood preventive measures.

Traditionally, structural methods have been used to prevent flooding. From hundreds of years, dikes were created along the rivers to protect against flooding and inundation. Later on, when the benefits of delaying runoff became clear, other sorts of civil engineering projects, such as those aimed at improving flood retention capacity, were also implemented. Flood protection can be achieved through a wide range of structural methods mentioned in the following:

Structural Measures

1. Building of embankments and dikes
2. Building of Storm surge barriers
3. Setting up polders along with pumps
4. Building of diversion canals
5. Building of reservoirs
6. To Increase capacity of channel conveyance

Fig. 3 Methods of flood vulnerability reduction. Source ([Verwey Adri, 2017](#))

7. Developing dry polders and detention basins
8. Developing sand barriers and coastal lagoons
9. Developing elevated highways
10. Terrain elevation in new urban projects

Nonstructural Measures

The following nonstructural measures also play a vital role in reducing flood hazard.

1. Reforestation at river basins
2. Agricultural Regulations
3. Improved river basin infiltration
4. Enhanced reservoir operating rules

5. Flood zoning and mapping
6. Guidelines for infrastructure development in floodplains
7. Flood forecasting and warning system
8. Flood insurance
9. Public awareness and training

The exposure of a region/area to floods is determined by the infrastructure, economic activities, magnitude of encroachments in watershed areas, river banks and beds, and the level of urbanization. To mitigate the exposure, various steps can be initiated to safeguard existing infrastructure and to minimize the future developmental projects. The various measures that help in reducing the exposure are as follows:

1. Regulations and planning for land use
2. Building floating houses
3. Construction of flood-resistant structures
4. Resettlement and acquiring property

The report of the Comptroller and Auditor General points out that it was poor governance that turned these floods so disastrous. Many flaws on the part of planning, reservoir management, flood forecasting, and capacity building have been mentioned in this report.

Conclusion

The devastating flood of August 2018 created havoc across the state of Kerala and made a devastating impact on its socioeconomic environment. Many risk drivers, viz., extreme rainfall, poor dam management, sand and stone quarrying, deforestation, etc., turned this flood more calamitous. It was more a result of poor human management than nature's fury. Even after the Western Ghats Ecology Expert Panel's regular warnings, the administration didn't take adequate measures to regulate the abuse of Coastal Zone regulations. The devastation exposed the failure of the administration in ensuring adequate measures of mitigation and preparedness. The recent report by the Comptroller and Auditor General (CAG) has chastised the State administration for shortcomings in policy and infrastructure that hampered the response for this flood. The report states that it was poor governance that turned these floods so disastrous. The administration showed failure in planning, reservoir management, flood forecasting, and capacity building measures. Kerala being a disaster-prone state, it is imperative that the administration must act upon the targets and priorities set by the Sendai Framework for Disaster Risk Reduction 2015–2030 to prevent future disasters and minimize the existing risk from other disasters as well. The administration needs to be proactive and bring all the stakeholders together to put a joint effort in this regard. The Sendai Framework helps to mitigate the existing risk and prevent new ones based on the concept of

“Build back Better,” integrated water resources management, people-centric approach, judicious use of natural resources, use of latest technology, innovation, and knowledge. Disasters will happen and we cannot stop them but what we surely can do is to minimize their impact so that the loss of lives, damage to property and infrastructure, and loss to the environment is as minimal as possible.

exercise is to restore lives and livelihoods of the people, refurbish institutions and social networks. Moreover, the recovery exercise is aimed to “build-back better.” This means that the effort is not just to restore the system to pre-disaster levels but rather to address the underlying systemic risks and vulnerabilities that led to the disaster in the first place. Such an intervention will help in preventing future disasters. NGOs have come to play a complementary role in livelihood restoration by providing finance, market intelligence, re-skilling and up-skilling disaster survivors. In case of Gujarat, intervention by SEWA transformed lives of unskilled women survivors and also aided in their psychosocial recovery. In terms of support to agriculture, industry, and services the reconstruction exercise has been evaluated by placing the emphasis merely on the number of beneficiaries, discounting for factors like assistance as proportion of damage, beneficiaries as proportion of people affected, etc. There seems to be consensus across policy documents that livelihood assistance can potentially ensure food security and enable housing reconstruction; however concomitant focus has not been given to the same.

The attempt through this chapter is to revisit the experience of post-disaster livelihood restoration.

Keywords

Livelihoods · Disaster · Recovery · Reconstruction

Introduction

From the Needs Assessment reports and financial resource allocation it is clear that livelihood is a crucial component disaster recovery, only next to housing reconstruction in importance.

The aim of any recovery exercise is to restore lives and livelihoods of the people and refurbish institutions and social networks. Moreover, the recovery exercise is aimed to “build-back better.” This means that the effort is not just to restore the system to pre-disaster levels but rather to address the underlying systemic risks and vulnerabilities that led to the disaster in the first place. Such an intervention will help in preventing future disasters.

Gujarat Reconstruction and Rehabilitation Policy: Livelihood Support Program

Under this, the government included credit supply for self-employed, provisioning workshops and infrastructure for artisans, farm input, support to industries, traders, and tourism sector.

Damage and Loss Assessment

The damage and loss assessment exercise was entirely government led. The team comprised of a government engineer, an official of the state government department, and a headmaster. The mandate of the team was to look at losses to houses, public buildings and infrastructure (Table 1).

As is evident, housing loss made up the majority share of total losses about 52%, followed by productive sector (20.6%), which includes agriculture, industry and services, and infrastructural losses (15.7%) (Table 2).

As regards the three sectors of economy, primary sector has registered maximum losses (53.8%), followed by the tertiary sector (35.4%) and manufacturing sector (10.7%). The aggregate loss to sectors of economy is estimated at INR 28423 crore (Table 3).

Even when it is primary sector that has faced the major brunt of the disaster (53.8% of total economic losses), in the estimated recovery cost share it lags behind at 22.2%. Industries (all categories put together) account for 73% of total recovery cost share. While it may be argued that cost of plant machinery and equipment is bound to be capital intensive, even then financial estimation is seemingly disproportionate. It seems to ignore the revival needs of the primary sector and service sector alike viz. a viz. the static and dynamic losses that these sectors have witnessed (Table 4).

As regards livelihood restoration, information provided is severely limited. Only data on number of beneficiaries has been released. It does not reveal what proportions of affected people have received these benefits in reality. Besides, there is no clarity on quantum of assistance provided; the figures vary from source to source. However, there is an indication that the support provided is meager with respect to damage. In some cases, such support served to be only of “token” significance (Tables 5, 6, 7, and 8).

In terms of support to agriculture, industry, and services, the reconstruction exercise has been evaluated by placing the emphasis merely on number of beneficiaries, discounting for factors like assistance as proportion of damage, beneficiaries as proportion of people affected, etc. The effort seems to be to readily declare the reconstruction exercise as a success without confronting more nuanced challenges.

Livelihood Restoration in Gujarat

The reconstruction policy document at its very beginning underlines that livelihood restoration is the thrust area of rehabilitation program. The document acknowledges the economic realities of Kutch region in accepting the significance of handicrafts. A revolving fund of INR 15 crore for working capital assistance was instituted. SIDBI announced a refinance scheme on concessional terms and conditions. The rehabilitation policy clearly states that it will seek the “active participation” of commercial banks, International Finance Institutions, and microfinance agencies in livelihood restoration activities. The UNDP, ILO all were roped in for different works.

Schemes announced for livelihood support are:

1. Short-Term Recovery Assistance

It promised to provide loan up to INR 2 lakh to self-employed people. Those who were employed in village and cottage industry, commercial banks and financial institutions would provide loans with subsidy.

Under the scheme, toolkit up to INR 2500 was to be provided to self-employed workers.

For temporary construction of work sheds, support of up to INR 5000 was to be provided, which was reported to be grossly inadequate.

Provision of assistance up to INR 24000 was made for toolkit for handicraft artisans.

2. Long-term Economic Assistance

Under this scheme, permanent worksheds of 20–25 sq. m were promised for each artisan. Also, the Rural Industries Development Centre was proposed at 50 locations for providing infrastructure to the tune of INR 4.5 crore. Besides, 24 mini handloom-handicraft parks at an estimated cost of INR 1 crore each (with 50% government assistance) were promised. Additionally, eight district level handloom- handicraft parks with a per unit cost of INR 2 crore each were also to be set up.

A Revolving Fund of INR 15 crore was to be created for rehabilitation of self-employed in village and cottage industries.

3. Assistance for Revival of Agriculture

For those engaged in agriculture sector, an immediate assistance of INR 15000 was provided. In case farm equipment were damaged or destroyed, assistance was provided in the range INR 2500–10,000. In case of damage to irrigation assets, the government promised to compensate 50–60% of the restoration cost subject to a ceiling of INR 1 lakh.

4. Assistance for Revival of Industry

Special package was announced for salt farmers, which promised to compensate them up to INR 5000. Besides, assistance up to 60% of repair and reconstruction cost was announced for all micro, small, and medium enterprises in seismic zones IV and V with a ceiling of INR 60 lakh. Outside the zone, assistance was provided up to 50% or INR 30 lakh whichever was greater. Assistance of 20 lakh (Zone IV, V) and

Table 9 Tax exemption in Gujarat

1	Investment up to INR 10 crore	100	5 years
2	Investment in the range INR 10–50 crore	100	7 years
3	Investment more than INR 50 crore	100	10 years

Source: Gujarat State Reconstruction Policy Document

10 lakh (other zones) for 2 years was given for interest liabilities to pending loans. Stamp Duty exemption was also provided on financial transactions, royalty was exempted on materials, which were produced or utilized in Kutch. Additionally, relief to trade, services – like retail outlets, nursing homes and restaurants. The rehabilitation policy acknowledges the significance of tourism sector to the economy of Kutch. In order to revive the tourism sector, the government promised to pay up to 60% of the cost of repair/reconstruction subject to the ceiling of INR 60 lakh.

Special Incentive Scheme (2001–2004) was announced by the Gujarat State Government to trigger industrial development in Kutch. Under this scheme cent percent tax exemption was provided for various categories of investments (Table 9).

This was in addition to excise exemption scheme declared by the Central government.

Such tax sops were expected to revive the economy of Kutch.

For salt pan workers, relief was provided in the range of INR 3000–5000. For shop owners with damaged property, benefits were provided between INR 3000 and 6000. In case of artisans in cottage industries and self-employed, subsidy assistance was provided to the tune of 60% of loans for working capital subject to a ceiling of INR 2 lakh. For handloom weavers, assistance was provided at INR 10,000 per handloom weaver. The reconstruction policy document asserts that livelihood assistance can potentially ensure food security and enable housing reconstruction. At the same time, housing reconstruction can ensure that home based-economic activities like weaving, handicraft, etc., may resume. The livelihood section of the reconstruction policy document ends in anticipation to throw up greater opportunities of employment.

Needs of Vulnerable Population

In the wake of the earthquake, livelihood restoration strategies thus conceived were three pronged: immediate restoration of livelihood; enhancing the skills of artisans; and empowering the artisans to market their skills. Additionally, schemes for small scale industries and agriculture were also introduced. Assistance was provided in the form of free kits, allowance for structural damage, working capital assistance, subsidized loans, training, and market.

In the post disaster scenario landless laborers and marginal farmers need greater support from the State. They ought to be reskilled and provided alternative livelihood options.

Quantum of Loss

Due to massive earthquake in Gujarat (2001), agriculture was severely affected. Two years of drought preceded the earthquake and therefore it was a dual tragedy. The official statistics of state government of Gujarat pegs total damage and loss at INR 544 crores. The loss of assets and infrastructure in private sector and public sector agriculture was estimated to be INR 510 crores and 35 crores, respectively. Major damage was reported in irrigation assets such as pumps, tube wells, water storage tanks, farm equipment, inputs, and livestock. The public sector loss component included loss to government agricultural university, dairy cooperative building, etc. Output losses were estimated to be to the tune of INR 230 crores mostly due to late harvesting of crops, lack of timely irrigation, and provision of farm storage.

Industry

Industrial units and machinery were damaged in districts like Kutch, Rajkot, Bhavnagar, Surendranagar, Patan, and Jamnagar. More than 3000 small-scale and numerous medium and large-scale enterprises were assessed to have suffered a collective damage of INR 340 crores.

Gujarat Industrial Development Corporation estates in Bhuj and Ajnar suffered tremendous damage. In Gandhidham and Kutch wood-based industries suffered damage, in Rajkot ceramic-based industries. The Indian Farmer Fertilizer Cooperative Limited (IFFCO) at Kandla was also affected. Large number of people in Kutch who depended on handicraft and handloom lost their livelihood. Total industrial losses was estimated to be around INR 1800 crore.

Post Disaster Assistance for Industrial Units

In case of small, medium, and bigger industrial units, which were situated in seismic zone IV and V, cash assistance to the tune of 60% of total investment with an upper limit of INR 60 lakh rupees was provided. Additionally, provision was made for zero interest loan for 2 years on working capital and exemption from electricity and stamp duty. The Reserve Bank of India also simultaneously announced various relief packages to be provided by banks to affected population. It involved relaxation of norms in payment of impending loans and sanction of fresh loans on lenient terms to those who had suffered losses.

Role of NGO

Under the Livelihood Security Project for Earthquake-affected Rural Households in Gujarat, Self-Employed Women's Association (SEWA) played an instrumental role restoring livelihoods for informal women workers. SEWA had empanelled close to 5 lakh women workers out of which 1 lakh are registered with IFAD. Under the livelihood assistance scheme, SEWA *Mahila Gram Haats* were created in addition to SEWA Trade Facilitation Centres. These centers helped in transforming local skills of women community like hand embroidery, crafts into a sustainable and commercially viable livelihood model. The facilitation center provided detailed market intelligence regarding demand of crafts, forums to sell products, and desirable product destinations. It is interesting to know that women in Kutch were traditionally engaged in unskilled agricultural labor; though they had training in handicraft and weaving over generations, they had little knowledge to channelize their expertise for income. SEWA presented an innovative model to create productive avenues for women survivors of disaster (Table 10).

Kerala

As regards sector-wise damage to livelihood, horticulture has registered maximum losses (77%) followed by agriculture (14%), and livestock (8.2%) (Table 11).

Table 10 Sector-wise estimated damage to livelihoods

Sectors	Financial losses (INR crore)	Percentage of total loss to livelihood
Agriculture	26	14.2
Horticulture	140	77
Fisheries	0.8	0.4
Livestock	15	8.2
Tourism-linked livelihoods	Not estimated	
Micro, small, and medium enterprises	Not estimated

Table 11 Category-wise affected workers, Kerala 2018

Category	Total workers (in lakh)	Affected workers (in lakh)	Percentage of workers affected	Days lost	Total man days lost (lakh)	Daily wage rate INR	Wage lost (INR crore)
Male workers	90.7	51.7	57	13	672	770	5100
Female workers	36.4	20.7	57	13	270	430	1165
Total	127.1	72.4	NA	NA	942	NA	6265

The disaster database of Kerala is more robust than that of Gujarat and Uttarakhand. In the two previous disasters, only number of beneficiaries and affected population was mentioned not clarifying what proportion of affected people were actually compensated in any manner (Table 12).

Kerala is also one of the first states for which Post Disaster Needs Assessment methodology as mandated by three international organizations was undertaken. The UNDP report puts seven districts of Kerala in the “100 per cent category”; these are Pathanamthitta, Alapuzha, Kottayam, Idukki, Ernakulum, Thrissur, and Wayanad. Thiruvananthapuram and Kasaragod were not affected. All other districts were affected to various degrees (Table 13).

Around 57% workers (both male and female) have suffered wage loss during the floods. Total wage loss registered is to the tune of INR 6265 crores (Table 14).

Total	127.1	72.4	57	13	942	NA	6265

Of all the sectors infrastructure has been greatly impacted and its recovery needs also constitute a majority (Table 15).

The table shows that uninsured losses make up nearly 96% of total losses. In order to compensate for uninsured losses, the survivors have to rely on ex-gratia grants and government assistance (Table 16).

HLEC considered the proposal put forward by ACS (LSGD) amounting to 1002 crore and decided to approve projects to the tune of Rs. 250 crore in the existing financial year (Table 17).

Uttarakhand Floods 2013: Impact on Livelihoods

Nature of Uttarakhand Disaster: Natural or Man-Induced?

The Uttarakhand disaster was significant not just for its scale but also for the reasons that exacerbated the impact of this disaster. A study of the economic history of the Uttarakhand illustrates that the tug of war for the region's resources can be traced back to the colonial era. On the one hand lay the community's customary rights over forests as source of livelihood while on the other hand laid the colonial interest in commercial exploitation of these forests. The latter through dynamics of power overrode the former with time. In the post-independence era, forests continued to be viewed as revenue generators. Mountainous areas failed to attract planner's attention in the early years as they were unable to generate surpluses. Even when Uttarakhand was made into a separate state on the premise that mountainous regions deserve special attention, the government narrowly pursued policy of industrialization in plains for the overall development of the state. Despite decent economic growth, social indicators like life expectancy, female literacy, and poverty rates fared dismally as compared to national averages.

Structural and Regional Imbalance

It is clear that in the decade leading to the floods (2002–2013), secondary and tertiary sectors were growing at a higher rate as compared to the primary sector, which employs close to 70% workforce in the state. In the 4 years preceding the deluge, growth rate had started declining before finally plateauing (Fig. 1).

The chart traces sectoral composition of GSDP over the decade leading to the disaster. It is evident that the share of secondary sector has seen a considerable rise, while agriculture has contracted. This is at a time when the dependence on agriculture has remained nearly constant.

For greater clarity we can contrast the case of Uttarakhand with the all-India scenario. It is seen that the industrial sector is contracting albeit very steadily. As opposed to this, in the same period, the contribution of agriculture sector to GDP (all India) has declined marginally (Figs. 2 and 3).

The state has shown high growth rate in recent years. It reached 6.7% in 2012–2013, from 2.9% in 2000. In the same period per capita income tripled. In sectoral composition, the share of services and industries has increased while that of agriculture and allied activities has concomitantly declined.

Primary sector in Uttarakhand is well diversified across major components of agriculture, forestry, and mining. However, the State has attained a low growth rate of less than 2% in almost all components of primary sector including agriculture. The growth in secondary sector has been on account of growth in construction and energy generation. The literature points out that developments in both sectors have detrimentally impacted the fragile ecology of the Himalayan state, which aggravated the impact of disaster.

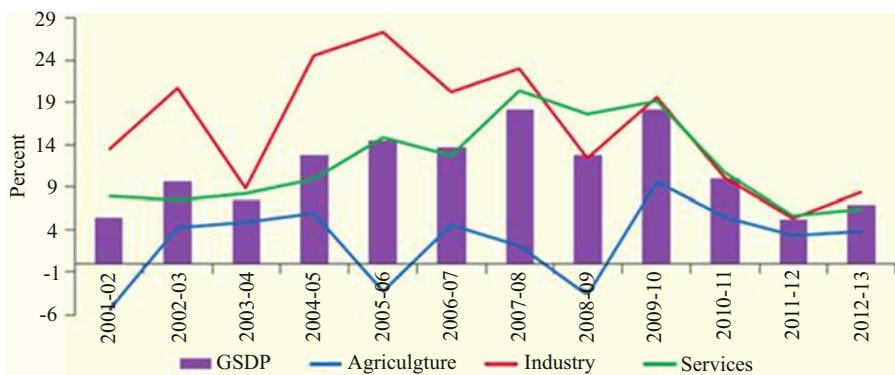

Fig. 1 GSDP growth rate at (2004–2005) prices, Uttarakhand

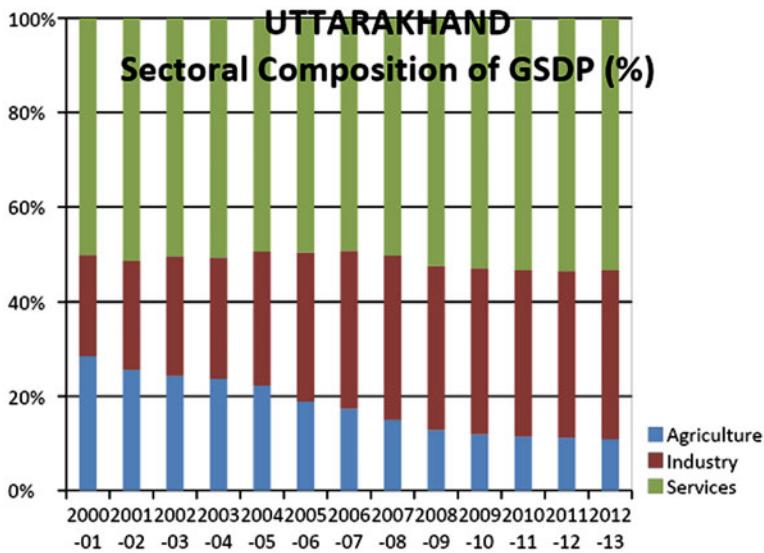

Fig. 2 Sectoral composition of GSDP Uttarakhand. (Source: CSO)

Uttarakhand largely depended on primary economic activities. However, after delineation of the separate state of Uttarakhand, state led industrialization robbed focus from the primary sector, which was the mainstay of the mountainous districts. Between 1993 and 2013, the contribution of primary sector to overall Gross State Domestic Product of the state declined by a whopping 72% (Oxfam India, 2014). In real terms, while primary sector grew at 22%, secondary and tertiary sectors grew at 245 and 168%, respectively in the decade 2003–2013. Furthermore, industrialization, which focuses on construction of roads, tunnels, bridges, dams, etc., interferes with the fragile ecology of the state and enhances its vulnerability to disasters putting lives and livelihoods in danger. Industrialization is pursued by diverting forest land

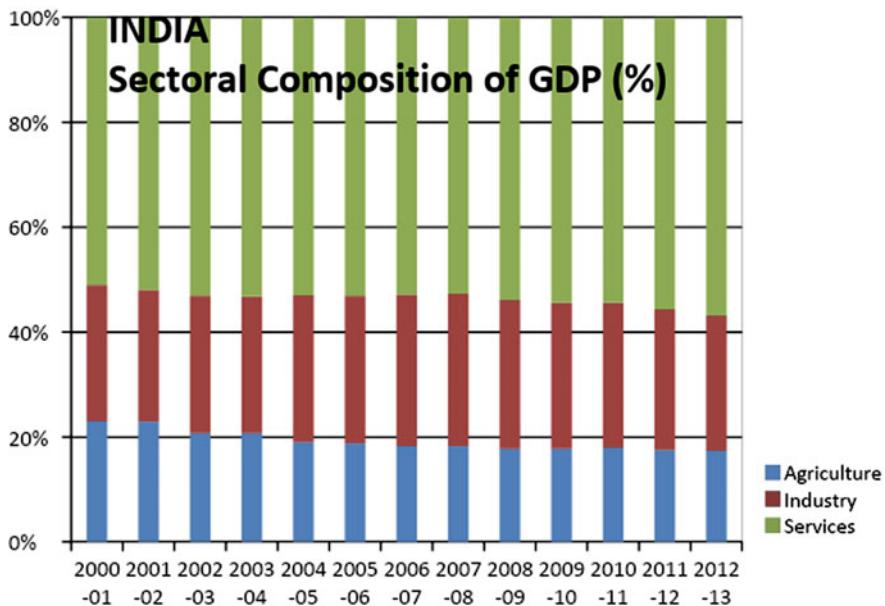

Fig. 3 Sectoral composition of GDP, India. (Source: CSO)

to non-forest uses. A host of environmental laws had been openly flouted in the process of industrialization, which was manifested in the unprecedented impact of the calamity.

More than half of Uttarakhand's workforce is engaged in agriculture. Meanwhile agriculture sector clocked the lowest growth rate during 2003–13. The concomitant contribution of agriculture to GSDP fell steeply from 16.7% to 7.8% during the same period. This clearly shows that households that are primarily dependent on agriculture have not been faring well over the decade leading to devastating floods of 2013. Financial instability is known to augment vulnerability, which impedes the coping capacity of communities to withstand disasters. A characteristic feature of the state's economy is that recent thrust toward industrialization-led growth is restricted to the plains alone. This is true even when there exists enough empirical evidence to substantiate successful sustainable natural resource-based industrialization in mountainous regions. Thus, the state suffers from regional imbalance, which has a tendency to amplify disaster losses.

Seventy-two per cent of the working population in mountainous districts is dependent on agriculture while only 35% in plains practice agriculture. The low rates of growth in agriculture impact the mountainous districts more harshly than the plain districts, which are experiencing industrialization-led growth. To top it all, 93% of all farmers in mountainous districts belong to the small and marginal category. Moreover, a meager 10% of the Net Sown Area in mountainous districts is irrigated as opposed to 84% in plain districts. Additionally, there also exist disparities in landholding size across various social groups.

Clearly, the kind of development pursued post attainment of statehood has benefitted all but those in whose name the struggle for statehood was justified in the first place. The state was formed on the premise to pursue development, which is locally suited and sustainable. However, it ended up borrowing the mainstream economic growth-led development model being practiced in dissimilar geographical locations across the country. There is a reason to believe that faulty development practices may have augmented the vulnerability of the mountainous regions, which exacerbated disaster consequences.

In the post disaster context, lack of land, livestock, and other livelihood assets poses a huge challenge in restoring lives of the people. In the case of Uttarakhand, the tourism-based economy was completely shattered. Operators of eateries, hotels, taxi and bus drivers, tourist guides, porters, and vendors were without business for days together.

The CAG in its report (2009) highlighted that contracts for developing hydroelectric plants were handed out to inexperienced players. For instance, textile manufacturers, agro processors were given contracts to build hydroelectric projects. The report further underlined that the state machinery to tackle disasters was dysfunctional. The nodal body for managing disasters at the state level had been instituted in 2007 but never met. At the time of audit, there was no document in place, which could guide the functioning of the State Disaster Management Authority. Even prior to 2013 deluge, there had been episodes of 27 major landslides, which had claimed close to 400 lives. The Geological Survey of India had identified roughly 100 villages, which were at a high risk. However, no attempts were made by the state government to relocate the villagers to safer places.

Oxfam India (2014) report highlights that a huge proportion of buildings, which were swept away in the flood and associated landslide were in reality illegal construction. Usually, construction is prohibited in a buffer of 200 m from the river bank. Shockingly enough, the State's *Vidhan sabha* building, Doon University campus and a government employee colony were partially situated in Rispana river bed. There was little motivation on the part of the government to eliminate such illegal construction as it was itself complicit.

The “Sustainable” Alternative

Given the experience of floods in 2013, it is advised that the mountain state pursues development, which is ecologically sensitive. An environmentally sensitive development model would entail more equitable growth in sync with the environment albeit at a lower rate.

It would augur well for the state to prioritize afforestation and link it with livelihood options. Community participation in ecosystem conservation is vital. Therefore *Van Panchayats* should be institutionalized, incentivized, and encouraged to protect forests. Attempts should be made to adhere to the tenets of Forest Rights Act, 2005 in both letter as well as spirit. Mountainous agriculture has long been

ignored; there should be a dedicated attempt to introduce cultivation of high value horticulture crops, processing of agro-produce, establishing market linkages to make mountainous agriculture remunerative.

Small, marginal farmers and landless laborers should be reskilled on priority basis in the aftermath of a disaster. While it is important to make agriculture profitable, it is equally important to diversify livelihood options for the poor, marginalized, and vulnerable population.

Community based eco-tourism, which combines environmental protection with local livelihoods, should be the way forward. It also has the potential to generate host to non-farm employment opportunities – tourist guides, cooks, caretakers, trekkers, porters, etc.

In case of loss of Common Property Resources, compensation to community must be made. The program for rehabilitation and recovery will yield best result if the plan is approved by *Gram Sabha* at various stages of its implementation. If beneficiaries of reconstruction process are involved in the decision-making process, it will increase transparency and it is likely that there will be a higher degree of acceptance of resultant projects. Additionally, effort should be made to consider voices of marginalized groups including women in order to design a wholesome plan, which is sensitive to needs of one and all.

System of governance should be decentralized and autonomous bodies like Biodiversity Management committees, Van *panchayats*, and Self Help Groups should be empowered.

Firstly, attempt should be made to improve the stock and quality of natural resources in the region like forest, river, soil, etc. Secondly, livelihood options that are suited to the geo-climatic situation of the site must be endorsed. For instance, Uttarakhand is suited for horticulture, apiculture, and floriculture. Agro processing industries with value chains and adequate market linkages can be set up. The ownership of such cooperatives and industries can lie with the community so that they become both the beneficiaries and custodians of the environment. Thirdly, schemes dedicated to rural development (like employment generation (MGNREGA), watershed management, afforestation) can be used to augment both the stock as well as quality of common property resources. These resources can be nurtured to be sources of remunerative livelihoods, which can be leveraged in post-disaster context. For example a healthy forest cover is not only an ecological imperative in mountainous region but also foundation for a range of sustainable livelihood options.

Fourthly, regions with fragile ecology should opt for community-based tourism. “Home stays” are part of popular culture in countries like Japan. It disperses the tourism pressure across the region. Besides, community becomes the direct beneficiary of revenue generated. The community-based tourism model enables deeper cross-cultural exchanges between the hosts and tourists (Table 18).

Table 18 Employment, livelihoods, and social protection

Sl. No.	Category of loss	Quantum

Fani Cyclone: Loss to Livelihood

Data on category wise quantum loss shows that MSME and Khadi industry was affected. Close to five million workers were affected to various degrees due to the cyclone. Besides, market zones also suffered (Table 19).

Districts with maximum crop losses (up to 94% of total crop lost) are Puri, Khurda, Jagatsinghpur. Approximately 25 lakh large animals were affected in addition to 54 lakh poultry birds and 10 lakh small animals.

Agriculture livestock and fisheries remained one of the worst affected sectors. Total loss was estimated at INR 3033 crore. Recovery needs were estimated at 2615 crore. Agriculture sector (including horticulture) accounted for more than half of total loss in this sector. Losses to standing crops would amount to prolonged production losses post-disaster. Due to large-scale agricultural losses, it was projected that rural incomes would remain depressed for a long time.

As is illustrated by figures above, the livestock sector also suffered greatly amounting to 40% of total losses in the sector. It has led to production losses in that there was shortage of milk, meat, egg, and other animal products.

Damage and Loss to Fishery Sector

It includes damage and loss up to 5% of the total losses in the sector. The Chilka fishery registered the maximum losses. The revival and restoration of assets in fishery and aquaculture should be the top priority for the government. The medium- and long-term recovery strategy must entail registering all aquaculture and inland fishery units, strengthening of value chain in fisheries sector and up-skilling of fishermen. As a preparedness measure, the need to adhere to and strengthen to Coastal Regulation Zone guidelines cannot be overemphasized. People living adjacent to coastal areas have a rather precarious existence. Measures should be taken to reduce the exposure to recurrent hazards like storm surges, cyclones, and coastal flooding while as an adaptive measure alternative livelihood should be promoted (Table 20).

Seventy per cent of all affected workers are in the horticulture sector, followed by agriculture and fisheries. Odisha is a top performer under the National Horticulture Mission and leads in floriculture, plantations, fruit, and spices cultivation (Table 21).

In terms of total quantum of losses too, the horticulture sector registered maximum losses to the tune of INR 266 crore, it was followed by the agriculture sector, fishery, and livestock industry (Table 22).

In case of quantum losses to enterprises in Odisha, the MSME sector suffered the maximum losses followed by tourism and handicraft industry (Table 23).

Table 20 Percentage of affected workers

Sl. Number	Sector	Number of workers affected	Percentage to total affected workers

Source: Compiled from Damage, Loss and Needs Assessment Report, Fani Cyclone 2019

In case of total days lost and total income loss, coastal districts of Puri, Khurda, and Cuttak suffered the maximum. The total income loss was estimated to be around INR 4105 crore.

Cyclone Recovery

Post Disaster Needs Assessment was conducted jointly by the World Bank, Asian Development Bank, and the United Nations. The Department of Economic Affairs was the nodal body managing the assessment exercise in India.

These international organizations reported the total reconstruction need in Fani Cyclone to be INR 29,315 crore. The report put the total damage at INR 16,465 crore and total loss at INR 7717 crore. The state government demanded assistance to the tune of INR 5277 crore. The central government, however, released only one tenth of the recovery needs of the State.

Recovery Strategy

The Government of Odisha received appreciation for significantly bringing down causalities of the 1999 Odisha super cyclone (about 10,000) to less than 100 in Fani 2019. Prior to this Odisha has already tackled Phailin cyclone successfully in 2013. However it has to be understood that much of the success attributed to the coastal state is on account of better preparedness strategies. While improving, preparedness can go a long way in mitigating disaster impact; it is well established that there are limits to preparedness. Thus a holistic disaster risk reduction exercise would focus on improving preparedness, mitigation, and recovery strategies. While the goal of zero mortality may soon become a reality for the state, the cause of concern is the rising losses to livelihood and housing. A comprehensive disaster risk governance would entail robust preparedness and recovery strategies.

Usually the physical and discernable losses as a result of disaster eclipse its deeper impact. While damage to infrastructure assumes primacy, the harsh reality is that subsequent disasters rob livelihoods and push people below poverty line. Disasters tend to augment inequality in already unequal societies. Thus a comprehensive recovery strategy should aim at mitigating systemic risks and vulnerabilities of society.

The government of Odisha has promised to build “resilience” in Housing, Livelihood, and Infrastructure.

Resilient Livelihoods

For long-term sustainable development, special care has to be taken that economic growth is commensurate with an increase in livelihood opportunities. While Odisha has made substantial progress in reducing poverty from 58% in 2005 to 33% in 2012, repeated cyclones push more people below the poverty line. There is a need to diversify livelihoods options and expand the social protection coverage.

The recovery strategy is usually envisaged in three stages: short term, medium term, and long term. The short-term strategy should entail providing cash assistance to survivors, restoration/replacement of damaged livelihood assets. Employment

Guarantee scheme under MGNREGA can be used to create livelihood assets. Formalizing the informal sector would also go a long way in mitigating future risks. The recovery phase should be used to up-skill existing workers. Near universal financial inclusion would help in providing monetary relief post-disaster. Needs of vulnerable sections should be top priority.

Livelihood Support

As coastal districts suffered overwhelming losses, fisher folk were worst affected. Subsidies for losses generally are given to those who own boats. In the process those working at seas without ownership of boats are easily overlooked.

Women headed houses are more vulnerable. There are small-scale economies where women are disproportionately engaged: vegetable selling, running small shops, and drying fish need to be compensated well.

Strategies of Livelihood Restoration and Promotion

Livelihood Promotion involves a range of interventions aimed at assisting people to put available assets to productive usage for earning a living. Livelihood promotion is different from livelihood restoration in that it aims to strengthen opportunities and look at sustainable and resilient livelihood options.

Experience of reconstruction in Indonesia shows that a rapid and sizeable injection of cash assistance through community-driven reconstruction model has the potential to boost economic recovery. Owner-driven reconstruction model allows individuals to customize housing design to suit needs of a workspace in case of household units.

The first step in livelihood restoration is rebuilding productive assets, which would support livelihoods. In the aftermath of disasters, when limited savings are exhausted, people are forced to resort to adverse coping mechanisms such as distress sale of assets and foregoing meals. In the absence of economic assistance, indebtedness increases.

Types of Assistance

Individual Cash grants

It seems to be the easiest and most popular method of providing relief to disaster survivors. However there are concerns about transparency and misuse of assistance. Besides, deciding the threshold of cash assistance is also challenging. It is difficult to determine what level of assistance would be enough for beneficiaries to resume economic activities.

Evidence from Myanmar has shown that targeting the vulnerable sections while providing cash grants is a useful strategy. It is also essential to monitor the impact of providing cash grants on beneficiaries.

Cash assistance is advantageous in that it transfers decision making to the beneficiaries who, ideally, would know best what they want. In the absence of supply side constraints, cash assistance is also capable of triggering growth. Even from an administrative perspective, providing direct cash assistance is the most transparent mechanism of giving benefits to survivors post-disaster.

However, an important limitation of direct cash assistance is that money which is sometimes intended to repair/buy productive assets is used to purchase daily necessities and repay debts. It is difficult to monitor cash usage. Studies have suggested that linking cash assistance to asset recovery is the best way forward.

Material Assistance

It is the most suitable measure when damaged asset needs to be repaired or replaced immediately. Material grants are a viable alternative when cash injection is likely to lead to inflation; there is considerable degree of corruption, and targeting beneficiaries is a difficult task. This method is successful when beneficiaries are made partners in identifying and selecting the materials they need. This mechanism was adopted by All India Disaster Mitigation Institute in case of *Bhuj* earthquake. The institute came up with a Livelihood Relief Fund (LRF), which was essentially a demand-driven scheme for asset replacement. AIDMI focused on the most marginalized sections who are often overlooked in other assistance schemes. In this case, the beneficiaries themselves identified the assets they needed, then they negotiated with the vendors for the lowest price, then AIDMI purchased those assets. Beneficiaries were empowered through the entire process. The institute was able to help more than 10,000 poor women, minorities, and informal laborers. In the case of the India Ocean Tsunami, the government rushed to buy boats for fishermen with the intention that this would trigger immediate growth. However, this haste led to an oversupply of boats, which were unsuitable to the technical and cultural sensibilities of the beneficiaries. Also experiences world over have shown that material assistance without due consultation with beneficiaries has achieved limited success.

Short-Term Income Generating Activities

It becomes vital to support disaster survivors, both for their economic as well as psychological well-being. Regular wages can help survivors meet their daily needs. Two important ways of creating short-term employment post-disaster are Cash for Work (CFW) and Public Work Employment initiatives. CFW is usually labor intensive aimed at recovery exercise. CFW initiatives have been successful largely when they were owned and led by community members where they determine the type of works, level of wages, and identification of beneficiaries.

CFW projects should aim at including most deprived sections. It is ideal for unskilled labor-intensive works, which are required in the aftermath of disasters. Examples of works include: restoration of public facilities, restoration of social infrastructure, reclaiming agricultural land, etc. AIDMI, while working on CFW

program in Gujarat, helped participants to upgrade their skills and to equip them for sustainable livelihood options.

Public Works Employment Schemes

It is used to engage disaster survivors into large-scale public works usually involving reconstruction activities. It differs from Cash for Work programs wherein participants identify the type of work, as in this case the government identifies the type and nature of work. Technical and managerial support is provided externally and workers are only given wages. Usually medium-term projects are implemented under this scheme. The Asian Development Bank recommends dam construction, laying irrigation infrastructure, dredging ports, agriculture terracing, road construction, etc., as part of public works employment scheme.

Community Block Grants

These grants are provided as a social fund to a group intended at building both social and physical capital. Community decides where and in what manner these funds would be invested. These funds are usually catered to vulnerable categories like women and chronically poor population.

The advantage of this scheme is that it puts community at the center of reconstruction exercise and government becomes a facilitator. This type of community-sensitive reconstruction approach has seen enormous success in the developing world. In the 1999 Orissa Super-cyclone, this strategy was widely used to rebuild fishing infrastructure. It was agreed that if funds were disbursed to individual households, it would not have been sufficient to rebuild boats. Providing lump sum amount to the community as a whole allows individuals to negotiate for best output. This fund helped in building the organizational capacity, assets, and livelihoods of community. Besides, resources were also procured locally, which gave rise to demand.

Conclusion

In post-disaster context, livelihood options should be seen in two different time frames: short term and long term. The aim should be to promote sustainable long-term livelihood opportunities. Besides, housing reconstruction and livelihood restoration should be seen in a continuum rather than separate entities, as it has been observed that some housing units also double up as economic work spaces.

While planning for livelihood restoration is underway, sustainable and diversified options should be considered in order to mitigate prospective losses. Experience in South Asia illustrates that MSMEs have been successfully leveraged for livelihood restoration. Livelihood promotion post disaster should be in sync with the long-term developmental goals of the State to the extent possible. This ensures smooth policy gradation and harmonization of short- and long-term strategies.

Microfinance Institutions play a significant role in rural contexts in livelihood provisioning. These institutions should be supported to undertake livelihood

promotion activities post-disaster. Micro-credit is a viable alternative to high interest informal loans and also keeps borrowers out of debt.

Of late, NGOs have been complementing the government's efforts in restoring livelihoods of survivors. Such a partnership has been beneficial and should be reinforced.

Abstract

Senior citizens are one of the vulnerable groups who suffered maximum at the time of disaster based on preparedness, response, and repossession. The different review of the literature identifies deficiencies in research on various issues of vulnerabilities of senior citizens during disasters and prepares strategies for handling those situations (Fernandez et al., *Prehospital Disast Med* 17(2): 67–74, 2002). In response to various disaster challenges of senior citizens, disaster resilience can be prepared. However, the present study attempts to ascertain and categorize the different challenges of senior citizens during the disaster and also to prepare the framework of disaster resilience of senior citizens with reference to the Amphan Cyclone in Kolkata. Thirty (UNDP, <https://ocm.iccrom.org/sdgs/sdg-11-sustainable-cities-and-communities/sdg-115-reduce-adverse-effects-natural-disasters>, 2015) senior citizens were interviewed based on purposive sampling, and data was analyzed based on quantitative and qualitative

understanding. The present study was an attempt to develop a resilience framework on the basis of senior citizens' *individual capacity* and excluded community and state resilience planning. It was found that the senior citizens have faced various infrastructural, physical, psychological, social, and economic challenges during the disaster and the level of vulnerability of senior citizens to the disaster was different on the basis of age, gender, health, economic condition, social support, availability of caregiver, etc. The disaster resilience framework was also created based on the five (5) P's – *Protect, Pack, Plan, Proceed, and Place*. True disaster resilience can be achieved through proper planning and inclusiveness of senior citizens.

Keywords

Disaster · Amphan Cyclone · Senior citizens · Challenges · Disaster resilience

Introduction

Population aging is considered one of the chief demographic problems of India at present. Ninety (90) million senior citizens (As a social category, "senior citizens" means any person, being a citizen of India, who has attained the age of 60 years or above. From the perspective of taxation, any individual resident who is 60 years or above in age but less than 80 years at any time during the previous year is considered as senior citizen for income tax purposes.) are projected to increase up to three-hundred and fifteen (315) million which will become 20% of the total population by 2050 (UNFPA-BKPAI- 2011/2014 1; United Nations, 2013). This growing part of senior citizens will be affected by disasters in the future. The Disaster Risk and Age Index anticipates the amplified rate and power of disasters which will affect the senior citizens also. The senior citizens are still not included in disaster planning in spite of a universal promise to include them. To address the vulnerabilities among the defenseless section of the society, the effort of a comprehensive Disaster Risk Reduction Policy (DRR) has been initiated (UNDRR, 2018). Senior citizens also have a right to be encompassed, included, and get a dignified life as they are a valuable resource for society (Help Age India report, 2019).

Demographic changes, urbanization, migration, climate change, and the increasing rate of disasters have affected the well-being of senior citizens (WHO, 2008). Senior citizens have to experience explicit vulnerabilities in terms of social, physical, and mental well-being during disasters. Senior citizens experience isolation, social and economic marginalization, esoteric information, and a dearth of appropriate post-emergency support amenities. Though senior citizens can meaningfully interpose to the preparedness, response, and recovery from disaster, their competencies are not properly utilized (Chan, 2020).

Disaster management involves a systematic procedure of preparation, organization, guidance, and control of all the disaster-affiliated activities at every stage – alleviation, preparation, retaliation, and recovery. The involvement of individuals,

communities, and local- to national-level authorities is essential for proper disaster management. The involvement of senior citizens in disaster management plans and processes is possible through proper consideration of disaster risk management systems for senior citizens. An inclusive approach to disaster preparedness is required to protect lives and promote equity and human rights for senior citizens (Help Age International report, 2019).

Vulnerability of Senior Citizens During Disaster

Senior citizens are reckoned to be vulnerable to emergency situations, based on the preparation, response, and recovery phase. The senior citizens, especially from BPL categories, marginalized, and disabled groups of people, are primarily susceptible to disasters (Buckle, 1999, p. 23). Senior citizens suffer from loss of function and different physical challenges which disrupt their everyday life. The senior citizens who function well before the disaster have their situation also aggravated during the disaster. The vulnerability of senior citizens differs based on certain situations:

Senior citizens suffering from chronic diseases: Common chronic health problems of senior citizens are mainly diabetes, COPD, hypertension, heart problems, and arthritis. During a disaster, the supply of health-care services and medicines is destroyed; nutritional requirements are also affected based on the hindrance of water and food supply. Disaster-related stress and physical excursion increase chronic diseases.

Precursory health problems or unaddressed health problems can quickly become critical for senior citizens during a disaster and even threaten their survival. Senior citizens who are dependent on home-based care services in their everyday life have to suffer most during the disaster situation and recovery.

Senior citizens suffering from restrictions in movement, disability, vision, and hearing: Constrained mobility of senior citizens increases vulnerability, and as such this segment of the population suffers from the threat of a potential disaster and is prone to difficulties in evacuating during a disaster situation.

Visualization, hearing deficiencies, movement-related problems, and cognitive problems of senior citizens make them more nervous and stressed to realize recovery procedures and instructions during the emergency. Moreover, the loss of spectacles or flexibility assistants during emergencies can upsurge dependence on others and put helpless senior citizens in a doubly jeopardized situation.

Senior citizens suffering from mental health issues: Senior citizens with dementia and any other mental health issues are more at risk during a disaster. According to a WHO report, emotional stress is the major health effect in post-disaster, in addition to different psychosomatic symptoms such as sleep and eating disorders, fatigue, depression, anxiety, loneliness, and social withdrawal (WHO report, 2008).

The general health of healthy senior citizens can be harshly threatened after the disaster. Continual exhaustion, interrupted sleep, impaired mobility, meagre diet, dehydration, hypothermia, hyperthermia, infections, and physical suffering excessively affect senior citizens. In unacquainted environments, weak senior citizens can

develop perplexity or confusion. Changes in medicinal regimes along with increased trauma and anxiety can hastily lead to dependency on others.

Other issues: Migrated or homeless senior citizens face more problems during the disaster. Senior citizens with low education lack communication messages before, during, and after disasters, and senior citizens who face various *changes* in life such as widowhood, retirement, and loss of significant others lack the ability to cope with daily life, intensifying the vulnerabilities of senior citizens (Brown et al., 2017). Senior citizens with *agism* are discriminated against, a negative view predominates, and old age is considered a time of loss and helplessness; old women are often victimized against their gender and other factors like disability. In situations like pre- and post-disaster, even elderly women have been identified as being prone to sexual violence and gender-based violence which ultimately puts them at greater risk (Streubert Speziale & Carpenter, 2011). It was observed that the senior citizens suffering from loneliness, social disconnectedness, depression, and distrust are vulnerable to suicide, especially during pandemics (Wand et al., 2020).

Review of Literature

As per the World Health Organization (WHO) Report (2008), “Senior citizens are resources for their families and communities, particularly during times of crisis. Their years of experience can make them models of personal resilience and sources of inspiration and practical knowledge. They give voluntary aid, care for grandchildren or neighbours, and participate in support or recovery initiatives. Including older persons in planning for and responding in emergencies thus benefits the whole community.”

The combined cases of experiences of senior citizens during the disaster event were reported by the WHO. Various experiences of senior citizens related to the Indian Ocean earthquake and tsunami (2004), the heat wave in France (2003), the Chernobyl nuclear power plant accident (1986), and the Lebanon armed conflict (2006) were reported by the WHO (2008).

Senior citizens with former exposure are apt to disaster preparedness. Morrow (1999) focused that the senior citizens having prior exposure to stressors during the disaster which are similar in character develop more psychological tolerance.

Ngo (2001) found that senior citizens having previous disaster exposure and fewer responsibilities and obligations experience lower psychological vulnerability. Other research also focused that prior exposure to an event across a community of all ages leads to lower psychological problems (Sattler et al., 2000).

The experience of all the senior citizens during a disaster is not the same; numerous factors generate a disproportionate impact on senior citizens, such as insufficient amenity provision, the reluctance of senior citizens to escape and protect themselves during the disaster, support and information for senior citizens, overseeing the consequence of disaster for senior citizens which lead to more misery, interruption of social support and social networks for enabling senior citizens to survive and recover, exclusion by policymakers, and self-exclusion to lessen the

disaster risk. As per the Help Age India Research Report, 2010, though senior citizens have equal rights like other age groups, still the problems and competencies of senior citizens are frequently ignored during disaster situations. According to the Help Age India report, after the Asian tsunami disaster, surprisingly only less than 1% of the funds were stipulated for senior citizens (Help Age International Report, 2014).

Four key factors are important for disaster management:

1. Communication – providing understandable, accurate, and practical information on time.
2. Coordination – confirming complementary action.
3. Education – increasing consciousness and knowledge about disasters.
4. Inclusion – confirming policies and activities on the basis of the needs, capacities, and vulnerabilities.

The Rationale

Natural disasters affect inhabitants of disaster-prone zones as a whole, but senior citizens are recognized as one of the extremely affected groups (Sanderson & Sharma, 2016). The senior citizens comprised 11.5% of the world's population (Bodstein et al., 2014), and 10.1% of the population in India [NSO, 2021] is a big portion of disaster sufferers (Farajzadeh et al., 2017) with high morbidity and mortality rates (Thomas et al., 2014).

Age inclusion in disaster risk reduction (DRR) has gained momentum in the Madrid International Plan of Action on Ageing (MIPAA), 2002, which was also endorsed by the United Nations General Assembly. The MIPAA has called attention to the need to "build a society for all ages" and address the different issues of elderly people in the twenty-first century. Three major priority action areas were recommended: (a) senior citizens and development, (b) advancing health and well-being of senior citizens, and (c) empowering and supportive environments for senior citizens.

With the succession of Hyogo Framework for Action 2005–2015: Building the Resilience of Nations and Communities to Disasters (HFA) by the Sendai Framework for Disaster Risk Reduction 2015–2030, four immediate, important action areas were recognized within its framework. They are (a) understanding disaster risk, (b) strengthening disaster risk governance, (c) investing in disaster reduction for resilience and increasing disaster preparedness for effective response, and (d) to "Build Back Better" in recovery, rehabilitation, and reconstruction. The framework acknowledges the realizable capacities and contribution of senior citizens and mentions: "Older persons have years of experience, knowledge, skills and wisdom, which are invaluable assets to decrease disaster hazards and they should be involved in the design of policies and mechanisms, including for primary warning before a disaster."

The Sustainable Development Goals of 2015 – the outcome document of the “2030 Agenda for Sustainable Development” – denotes the outcomes of the Sendai Framework and prospects for achievement of Sustainable Development Goals (SDGs) through DRR. As per SDG Target 11.5, “By 2030, a significant decrease of the figure of deaths and people affected and considerably reduce the direct financial fatalities relative to the global GDP caused by disasters, including water-related disasters, with a focus on protecting the poor and people in vulnerable situations” (UNDP, 2015). Again, in line with the Sendai Framework for Disaster Risk Reduction 2015–2030, SDG Target 11.b says: “By 2020, substantially increase the number of cities and human settlements adopting and implementing integrated policies and plans towards inclusion, resource efficiency, mitigation and adaptation to climate change, resilience to disasters, and develop and implement,” which will enhance the holistic disaster risk management at all levels.

Moreover, SDG Goal 13 emphasizes that climate change maximizes disaster risk and increases disaster risk management (DRM) costs. The Sendai Framework, an international document adopted by UN members, demands strengthening the assessment of disaster hazards and surveillance, including climate change scenarios and integration of disaster risk reduction (DRR) measures with climate change awareness programs. Senior citizens, women, and children are worst hit by climate change, and it has become significant to incorporate them in the plan of action.

The National Policy for Senior Citizens (NPSC), 2011, also focused on disaster safety of senior citizens. One of NPSC’s significant areas of intervention, 2011, was to offer equivalent access to food, shelter, meditational care, and other amenities to senior citizens during and after natural disasters and emergencies.

While various international bodies have given importance to the issues of vulnerabilities of senior citizens during the disaster, the present study was an attempt to understand various issues of vulnerabilities of senior citizens living in Kolkata, West Bengal, during the Amphan Cyclone Disaster.

Objectives

1. To identify the different challenges of senior citizens during the Amphan Cyclone* disaster in Kolkata.
2. To prepare the framework of disaster resilience for senior citizens.

Method

Variables

Senior citizens: The Maintenance and Welfare of Parents and Senior Citizens Act, 2007, endorsed by the Government of India demarcated a senior citizen as a person who has accomplished the age of 60 years or above (Parents and Senior Citizens Act, 2007).

Disaster: The Disaster Management Act, 2005, describes a disaster as a catastrophe, mishap, calamity, or grave manifestation in any locality that results in a significant loss of life or misery.

Disaster challenges: Problems faced by individuals during the disaster.

Disaster resilience: The Hyogo Framework for Action defines “disaster resilience as the capacity of individuals, communities and public and private organisations to organise themselves to learn from past disasters and reduce their risks to future ones, at international, regional, national and local levels” (UNISDR, 2005).

Sample

30 senior citizens (15 males and 15 females) were taken based on purposive sampling from Kolkata (KMC area) in West Bengal.

Sample Selection Criteria

- (a) **Selection of area:** Area affected most during the Amphan Cyclone in the municipal areas of Kolkata, West Bengal, i.e., South Kolkata, Borough 10, Ward No. 8 s2; Borough 14, Ward No. 124.
- (b) **Selection of respondents:** Senior citizens aged 60 years and above and who have suffered due to loss of physical resources, psychological stress, and the associated health-related disorders during the Amphan Cyclone.

Tools Used

The general information schedule consists of open-ended and close-ended questions on sociodemographic status, different issues of vulnerability during the Amphan Cyclone Disaster, and their preparedness (building resilience).

Data Collection

Data were collected through face-to-face interviews in November to December 2021.

Data Analysis

Data were analyzed on the basis of both qualitative and quantitative perspectives. The descriptive statistics model was used for quantitative understanding, and narratives were used for qualitative understanding.

*The Amphan Cyclone was a powerful super cyclone that caused various damages over East India in May 2020. The highest wind velocity was 240/km which continued for 1 minute. It has one of the costliest effects was approximately 13.6 billion dollars were fatalities due to this cyclone. In India, the cyclone-affected areas are Andaman, Odisha, Kolkata, and North and South 24 Parganas of West Bengal. Thousands of trees were uprooted, electricity and telecommunication collapsed, houses flattened, and vehicles collapsed. Many of the Kolkata city roads were flooded, and 14 million people were without a power supply. As per the report of *The Hindu*, the Ministry of Earth Sciences described the Amphan Cyclone as the

“Worst over for India” amidst the pandemic (Halder et al. (2021). The Amphan Cyclone was also categorized as a “super cyclonic storm” by the [India Meteorological Department](#).

Results and Interpretations

Table 1 shows the sociodemographic profile of Amphan-affected senior citizens living in Kolkata, West Bengal. Most senior citizens in this sample belonged to the 70–74 years of age group (53.3). The educational background of the respondents shows that most (43.3) of the respondents are graduates; most of the senior citizens

Anxiety	08 (53.3)	11 (73.3)	18 (60)
Depression	07 (46.6)	09 (60)	16 (53.3)
Loneliness	04 (26.6)	12 (80)	16 (53.3)
Frustration	08 (53.3)	09 (60)	17 (56.6)
Helplessness	11 (73.3)	10 (66.6)	21 (70)
Social issues			
Isolation	12 (80)	10 (66.6)	22 (73.3)
Lack of social support	14 (93.3)	09 (60)	23 (76.6)
Lack of caregiver	07 (46.6)	12 (80)	19 (63.3)
Restriction on activities	12 (80)	12 (80)	24 (80%)
Economic issues			
Lack of cash	12 (80)	08 (53.3)	20 (66)
Banking/ATM facilities	10 (66.6)	09 (60)	19 (63.3)

belong to the middle class as their monthly earnings are between Rs. 20,001 and 30,000; in case of marital status, most of the male senior citizens, i.e., 40%, are unmarried, and among females, 33.3% belong to the widow category. Regarding caste, most (56.6%) senior citizens belong to the general category; 60% of male and 53.3% of female senior citizens live with family, but 40% of male and 46.6% of female senior citizens live alone.

Table 2 shows various challenges of senior citizens during the Amphan Cyclone Disaster. It has been reported that the senior citizens have faced different infrastructural, physical, psychological, social, and economic issues during the Amphan Cyclone in Kolkata. 100% of the respondents have faced infrastructural problems related to electricity, telecommunications, drinking water, water facilities for sanitation, and health facilities; some of the senior citizens have faced different physical problems too such as breathing problems and problems related to chronic diseases as there was the unavailability of caregivers and physiotherapists, and the COVID-19

situation during the disaster increased the problem of senior citizens more. The respondents also reported various psychological problems: 33.3% of senior citizens have suffered from trauma, 60% of respondents have suffered from anxiety, 53.3% of them have faced depression and loneliness, 56.6% have faced frustration, and 70% of senior citizens have faced helplessness. Among the social problems that have also been reported by the respondents are isolation (73.3%), lack of social support (76.6%), lack of caregivers (63.3%), and restriction on activities (80%) due to the COVID-19 situation during the Amphan Cyclone. Some of the economic problems such as lack of cash (66%) and lack of banking or ATM facilities (63.3%) have also been identified by the respondents.

Mrs. Dhar, a 69-year-old widow and mother of NRI son, lives alone. She states that she had to struggle a lot during the Amphan Cyclone. She brought water from the water tank which is supplied by the Kolkata Municipal Corporation (KMC), for three days. However, she could manage only five bottles of water which helped her fulfil the need for drinking and also for overall routine occupations.

Mr. Sarkar, a 72-year-old widower, has been passing through the bouts of anxiety and frustrations during and after the Amphan Cyclone amidst COVID-19, 2020. As he was a COVID survivor too, he did not receive proper medical care from his family and doctor. He felt extreme isolation and was stranded in one room, and the disaster situation made him further feel left out.

The stress process model (Pearlin et al., 1990) proposed that a primary objective stressor disturbs the person through its influence on the secondary stressors a given individual experiences and appraises as challenging. As per the stress process model, the Amphan Cyclone also has created stress on the senior citizens, and they suffer from different challenges. The Amphan Cyclone arrived during the COVID-19 pandemic, and the senior citizens who had more risk of COVID infections become more vulnerable during the Amphan Cyclone Disaster. The lockdown and threat of COVID infection had already made seniors isolated from their family and the society, and the Amphan Cyclone made them more anxious and stressed not only for themselves but also for their family members.

Table 3 shows the opinion of senior citizens about disaster resilience during the Amphan Cyclone Disaster in Kolkata. Based on the responses of the respondents, disaster resilience can be categorized into five (Chan, 2020) “P” categories: *Plan, Pack, Protect, Proceed, and Place*.

The senior citizens have *planned* for the Amphan Cyclone based on the information received from news channels and print media (63.3%), children or relatives (60%), neighbors or friends (66.6%), and local clubs and local parties (50%).

After getting the information about the cyclone, they have *responded* on the basis of preparing themselves and their family members by packing dry foods (33.3%), storage of drinking water (40%), storage of candles and battery-operated torches (23.3%), storage of medicines (33.3%), and informed caregiver (50%).

The respondents *protected* themselves during the Amphan Cyclone Disaster by switching off the main electric board (73.3%), closing doors and windows (83.3%),

Table 3 Respondent's opinion about disaster resilience during the Amphan Cyclone Disaster

Disaster resilience (multiple responses based on yes response)	Male (N = 15) No. (%)	Female (N = 15) No. (%)	Total (N = 30) No. (%)
Plan			
News through TV channels, print media, etc.	12 (80)	07 (46.6)	19 (63.3)
Children or relatives informed	08 (53.3)	10 (66.6)	18 ((60))
Neighbors informed	04 (26.6)	06 (40)	20 (66.6)
Local clubs and political parties announced	08 (53.3)	07 (46.6)	15 (50)
Pack			
Storage of dry nonperishable foods	02 (13.3)	08 (53.3)	10 (33.3)
Storage of water (drinking and other usages)	02 (13.3)	10 (66.6)	12 (40)
Storage of candles, battery-operated torches	01 (0.6)	06 (40)	07 (23.3)
Storage of medicines	06 (40)	04 (26.6)	10 (33.3)
Informed caregiver	06 (40)	09 (15)	15 (50)
Protect			
Switch off the main electric board	12 (80)	10 (66.6)	22 (73.3)
Close doors and windows	11 (73.3)	14 (93.3)	25 (83.3)
Keep all the important documents in a safe place	04 (26.6)	05 (33.3)	09 (30)
Store sufficient cash amount	08 (53.3)	04 (26.6)	12 (40)
Proceed			
Stay in relatively empty rooms in the house	09 (60)	12 (80)	21 ((70))
All family members stay together	07 (46.6)	07 (46.6)	14 (46.6)
Place			
Supported by children and other relatives	08 (53.3)	09 (60)	17 (56.6)
Supported by neighbors	04 (26.6)	05 (33.3)	09 (30)
Supported by local club members	04 (26.6)	04 (26.6)	08 (26.6)
Supported by local political party members	08 (53.3)	07 (46.6)	15 (50)
Supported by NGOs	03 (20)	05 (33.3)	08 (26.6)
Supported by govt. – Provide water, other services	05 (33.3)	06 (40)	11 (36.6)
Self-recovered	06 (40)	07 (46.6)	13 (43.3)

keeping all important documents in a safe place (30%), and storing sufficient cash amounts (40%).

Respondent's opinions about staying in relatively empty rooms in the house (70%) and all family members staying together (47%) can be largely categorized under *Proceed*.

And the respondents have been *placed* with their families with the support received from children and other relatives (56.6%), neighbors (30%), local club members (26.6%), local political party members (50%), NGOs (26.6%), government policy (36.6%), and self-recovered (43.3%).

Mrs. Chatterjee, a 66-year-old widow, living with family, informs that she had taken necessary arrangements to face the cyclone as she was informed by her son and neighbors

about the cyclone, she had stored extra water both for drinking and for other usage and also candles, and she had located all the flower pots in the proper place and also stored some extra medicines.

Mr. Roy, a 74-year-old retired school teacher, living alone, states that after Amphan Cyclone, he was helped by the local club members to place him in his house as one big tree had fallen over it and broke one of the walls, and being alone, he was very helpless to take any action. The local club members and party members helped him during the emergency.

The Habitat for Humanity India, an NGO, successfully implemented resilience campaign which also focuses on the five (Chan, 2020) P's – the topmost five tasks to carry out during a disaster. The five (Chan, 2020) P's are *Protect, Pack, Plan, Proceed, and Place: Protect your valuables. Pack essentials like food, water, and medicines. Plan your evacuation route in advance. Proceed to evacuate the elderly, disabled, and children. Place your family at a disaster reprieve center.* The P stands for Pathways to Permanence, habitat's disaster risk reduction and response approach to assist families standing in the path of disasters to find lasting solutions to their shelter needs (Habitat, NGO report, 2015).

A qualitative research-based study among 17 focus groups who suffered from disaster risks focused that the senior citizens aged 65 or older can contribute a lot during the disaster in terms of their experience, funds, and relationship-building capacity. They can prepare themselves and also support others during a disaster. Specifically, senior citizens can initiate and mobilize social capital in their locality during a disaster. Senior citizens can contribute significant assets to disaster response (Howard et al., 2017). Thus, the present study also prepares the framework for disaster resilience on the basis of five (Chan, 2020) "P" categories – *Plan, Pack, Protect, Proceed, and Place* – based on the experience of the senior citizens in Kolkata during the Amphan Cyclone.

Conclusion

This study attempted to understand the different challenges of senior citizens during disasters and to prepare the framework of disaster resilience for senior citizens. Senior citizens of Kolkata were interviewed on the basis of purposive sampling to understand their challenges during the Amphan Cyclone in 2020 and also their coping strategies during that emergency.

The larger conclusion one can draw from the data on demographic profile is that the socioeconomic locus of the senior citizens explains their vulnerability during the disasters. The lower the rung is, the higher the vulnerabilities. Ardalan et al. (2009) suggested that socioeconomic and cultural backgrounds have had an enormous influence on senior citizens' vulnerability and their reaction to a disaster (Ardalan et al., 2009). The result of the analysis also shows that the senior citizens have to face different challenges during the Amphan Cyclone which can be categorized into five categories: *infrastructural, physical, psychological, social, and economic.*

Senior citizens have faced different infrastructural problems related to electricity, telecommunications, drinking water, water facilities for sanitation, and health

facilities; physical problems like breathing problems and problems related to chronic diseases as there was unavailability of caregivers and physiotherapists; psychological problems such as trauma, anxiety, depression, loneliness, frustration, and helplessness; social problems which include isolation, lack of social support, lack of caregivers, and restriction on activities due to the COVID-19 situation during the Amphan Cyclone; and economic problems like lack of cash and lack of banking or ATM facilities.

The stress process model (Pearlin et al., 1990) supports the findings of the challenges of senior citizens during the Amphan Cyclone. The Amphan Cyclone created stress on the senior citizens which resulted in different challenges for them during the disaster. The COVID infection and lockdown situation had already put the seniors into isolation from their family and society, and Amphan made them more anxious and helpless not only for themselves but also for their family members. Seniors had become triply jeopardized due to their age, COVID infections, and Amphan Cyclone.

The present study also tried to prepare one framework of disaster resilience on the basis of the experience of senior citizens during the Amphan Cyclone, and based on the responses of the respondents, a disaster resilience framework was prepared which can be understood in terms of five (Chan, 2020) “P” categories: *Plan, Pack, Protect, Proceed, and Place*. The *plan* is possible through the information received before the disaster which comes with under-*preparedness*; *pack* leads to the storage of essential goods; *protect* suggests various protective measures which together come under *response*; *proceed* recommends taking initiatives for protection; and *place* suggests the regaining previous situation come under the *recovery* process of resilience building.

Building resilience is a process of supporting communities to accomplish change and be better prepared to resist and recover from social, environmental, and economic stresses. The resilience-building approach recognizes that communities have proficient information about their local environment and are best positioned to observe, learn, experiment, and respond to the risks they face. Resilience-building activities cover an extensive range of sectors, including gender, disaster risk reduction (DRR), livelihoods, health, social protection, and natural resource management (Help age International, 2015).

Zhu et al. (2017) found that attaining better resilience and managing disasters are possible through understanding various vulnerabilities among the senior citizens, and those need to be identified from their own unique perceptions (Zhu & Sun, 2017).

The Active Ageing Framework suggests the approach to mainstreaming the reflections of senior citizens into the disaster management system. The active aging process enhances opportunities for health, participation, and security to augment the quality of life of senior citizens. The activity theory (Havinghurst, 1961) which is a functionalist approach asserts that successful aging can be attained only by continuing their roles and relationships which can be related to the making of a framework for integrating the needs and contributions of senior citizens into disaster management programs (Help age International, 2015).

It is true that the vulnerability of senior citizens is started acquiring attention at present, but a proper policy framework is yet to develop in relation to the particular needs of the senior citizens. Unique capacities and contributions of senior citizens should be recognized for preparing policies for disasters. It is important to keep in mind that a large segment of senior citizens with vulnerabilities needs to be addressed, and proper disaster resilience needs to be implemented by utilizing the experience of senior citizens.

One of the significant conclusions and thus a profound recommendation could emanate from the fact that the state government must be updated with the infrastructure and logistical preparedness for facing any natural disaster situation, since the state is located in a disaster-prone geographical area. Extending the arguments of the pre-preparation, it would also be important that, in line with pre-, during, and post-disasters, the psychological preparation of the disaster-prone population must also be in place. In fact, the post-traumatic counselling of the population is the most critical stage.

The present study has limitations. The sample size was small due to the lack of proper identification of respondents who had suffered most during the Amphan Cyclone. Though the basic criteria for selection of respondents were 60 years, researchers have found that the respondents 65 years and above are those who have suffered more during the cyclone in Kolkata. The major focus of the research was to understand the challenges and prepare the framework of disaster resilience for senior citizens on the basis of the qualitative experiences of the respondents and different categories of challenges, and the disaster resilience framework was developed by analyzing the qualitative answers of the respondents. The Hyogo Framework for Action defines “disaster resilience as the capacity of individuals, communities and public and private organisations to organise themselves to learn from past disasters and reduce their risks to future ones, at international, regional, national and local levels” (UNISDR, 2005). But the present study was an attempt to develop a resilience framework on the basis of senior citizens’ *individual capacity* to learn from past disasters and reduce their risks in the future; the research did not address a community, public, and private organization framework. In spite of these limitations, the study provided valuable insights for finding out the different challenges of senior citizens and tried to develop one framework of disaster resilience on the basis of five (Chan, 2020) P’s.

Abstract

Municipalities (city governments) in India are deeply embedded within the societies they serve. They are at the forefront of coordinating essential services during a disaster, such as the COVID-19 pandemic, by providing food security to vulnerable populations and setting up quarantine facilities, housing, sanitation, public works maintenance, and so on. This is despite the fact that most municipalities have no power to act autonomously in their functional areas and rely heavily on grants and transfers from state and central governments to perform their routine civic functions. Although the *Constitution (Seventy-fourth Amendment) Act, 1992*, obligates states to empower municipalities with functions, finances, and functionaries, only a few states have taken steps to empower municipalities through decentralization and devolution of powers. Most state

governments treat municipalities as their extension and not as an “institution of self-government” that should be considered an autonomous unit within the federation. This chapter highlights how the current governance structure of cities has proved ineffective in mitigating the impact of disasters like the COVID-19 pandemic. It argues that a lack of agency on the part of municipal governments over their administrative and financial relationships with states has resulted in them being institutionally disempowered and depoliticized. Policy recommendations following this line of thinking will conclude this chapter.

Local government · Indian Constitution · COVID-19 pandemic · Decentralization · Autonomy

Introduction

The stress-testing provided by the COVID-19 pandemic (the pandemic) has magnified several shortcomings in India’s highly centripetal government structure and exposed fault lines in legislative and governance frameworks in dealing with public health emergencies (ORF Colaba Edit 2021). Both central and state governments were confronted with archaic laws and obdurate governance structures that were hard-pressed in dealing with a dynamic situation that needed prompt redressal. Through lessons learnt with the onset and management of the pandemic from March 2020 till now, scholars in different fields of study are now able to assess and understand how they might go forward in improving India’s public health emergency framework (VIDHI, 2021). Though diverse in their fields, they indicate the role of state capacity and provide useful lessons from the pandemic.

The common thread connecting these lessons is that India is too large, complex, and diverse to be run by centralized decrees. Hence, decentralization and devolution of powers to local governments enshrined in part IX (panchayats) and IXA (municipalities) of the Indian Constitution is essential for preparedness, management, and mitigation of disasters like the pandemic (James, 2020). At the outset, it should be noted that the focus of this chapter is on municipalities, i.e., urban local governments, and not on panchayats (rural local governments). The role of municipalities, from managing lockdowns to planning for the reception of an influx of migrant labors, was forefront throughout the pandemic (MOHFW, 2020). It demonstrated to policymakers that municipalities need to be comprehensively empowered to provide the last-mile delivery of government services. It has become further evident that municipalities should not be seen as mere providers of basic civic amenities but actual custodians of the urban local governance in India.

Although this idea of decentralized governance through municipalities has been in “constitutional existence” from the early 1990s, most state governments overlook the principles of federalism when it comes to sharing powers with these bodies (Jha, 2022a, b). In fact, there are overwhelming roadblocks to better urban governance in

India. The reasons include a broken state-local governments relation, disempowered third-tier government, and a political establishment that is oblivious to developing an institutional framework that would make municipalities independent in forms, functions, and finances (Ahluwalia, 2019; Oommen, 2020). Unless institutional reforms are put in place to address these challenges, the process of devolution of powers and finances to municipalities in keeping with the obligation under the 74th Amendment to the Indian Constitution will never be realized.

This chapter demonstrates the need for these reforms by highlighting the impotence of India's municipal institutions during the pandemic. The chapter starts by briefly explaining India's urban governance model. It uses the COVID-19 pandemic as a case study to demonstrate the importance of decentralized governance in cities during a disaster. In doing so, it also highlights challenges faced by municipalities during crises. It argues that the lack of agency on the part of municipal governments over their administrative and financial relationship with states affects their preparedness during a disaster like the current pandemic. The chapter concludes by arguing that decentralization and devolution of powers and finances should be the axis around which reforms should be implemented and imagined for urban local bodies functioning during a disaster.

The authors acknowledge that the urban governance in India is part of the State List of the Constitution, which makes administrative frameworks and regulations of municipalities vary across states. However, experts have highlighted that municipalities across India face various challenges that justify the adoption of a uniform approach towards issues (Second Administrative Reforms Commission, 2007). Therefore, the chapter uses examples of the functioning of various municipalities during the pandemic across the country. Furthermore, the chapter interchangeably uses the term municipalities and urban local bodies (ULBs) to maintain coherency and uniformity in the use of terminologies.

Rise of Independent Urban Local Governance in India: From Constitutional Oblivion to Existence

The evolution of urban governance in India is of a more recent origin. As the country moves away from the aphorism "India lives in its villages" to "India lives in its cities," the quality of governance will be increasingly determined by how urban local bodies govern themselves (Jha, 2020a, b). Although framers of the Indian Constitution after much debate inserted *Art. 40* in the *Directive Principles* obligating state governments to organize panchayats in rural areas (Constitution of India, 1950 art. 40 (The State shall take steps to organize village panchayats and endow them with such powers and authority as may be necessary to enable them to function as units of self-government)), no corresponding duty was imposed on states concerning urban governance (Constitution Assembly of India Debates 1949). The only reference to urban self-government could be found in Entry 5 in the State List of the Indian Constitution (Constitution) that placed the responsibility of urban developments on state governments (Constitution of India, 1950 [Seventh Schedule – List II (State

List) – Entry 5: Local government, that is to say, the constitution and powers of municipal corporations, improvement trusts, districts boards, mining settlement authorities and other local authorities for the purpose of local self-government or village administration.]). This lack of constitutional obligation to empower local governments in cities and towns coupled with a political system that is heavily biased towards the rural sector resulted in the neglect of urban areas across India (Kazmin, 2016). This is so notwithstanding the fact that the country has witnessed an uninterrupted urbanizing trend since 1911 at an average of 2.09 percent per decade (Jha, 2020a, b).

In the first five decades following independence, urban governance was characterized by incomprehensive and inadequate municipal laws and near-absolute administrative, functional, financial control of state governments over ULBs (Jha, 2020a). Political meddling in the functional and financial domain of ULBs and usurping of elected leaders of ULBs from the planning function of cities got institutionalized across the country. Wherever some modicum of the civic role was given to ULBs, the state ensured that all final approvals were retained. Bhattacharya (1976) further notes that in the post-independence era, “the state government followed an ambivalent policy towards the municipal rule while ceding powers on papers but putting checks and restraints on exercising power by the local bodies.” In hindsight, most Indian states did not meet the necessary conditions of independence, decentralization, and devolution of powers and finances required for the effective functioning of ULBs (Aijaz, 2008).

With cities being the drivers of India’s economic growth, this lack of institutional empowerment of ULBs started affecting governments’ aim of improving the quality of life of a rapidly growing urban population. India’s planners and policymakers soon realized that urban local governments need to promote popular participation, engage in social transformation, and equally distribute resources to spur economic growth in cities (Muttalib & Ali, 1982). The first concrete step on this front was taken in 1985 when a separate Ministry of Urban Development was set up in the center to develop a uniform urbanization policy in India. After that, based on the L.M. Singhvi Committee (1986) report, the central government introduced the *Constitution 64th Amendment Bill 1990* in the Parliament to provide constitutional status to rural and urban local bodies. Though the Bill was passed by the Lok Sabha, the lower house of the Parliament, it was defeated in the Rajya Sabha, the upper house of the Parliament, in 1989 due to concerns over ULBs usurping powers of state governments.

In 1992, the central government (the government) introduced a new bill based on the previous amendment bill with few modifications to accord constitutional status to local governments. The bill was finally enacted as the *Constitution 74th Amendment Act (CAA)*, which inserted chapter IXA in the constitution and formally recognized ULBs as the third level of government. The CAA stipulated three levels of municipal bodies to be set up in the country and dealt with issues

relating to their structure and composition, reservation of seats, elections, powers, functions, and finances (The Constitution (74th Amendment) Act, 1992 inserted Part IX (s. 243P – 243ZG) in the Indian Constitution). A notable development was the mandate that state governments would transfer to local governments a set of specified functions under *Schedule XII* of the Constitution (The Constitution (74th Amendment) Act, 1992 s. 243W). It included subject matters relating to urban planning, public health, water supply, sanitation, and waste management – all of which aimed to increase the participation of local communities in the decision-making of their cities and towns. Another positive development brought in by the CAA was the introduction of mandatory reservations for women, scheduled castes, scheduled Tribes, and other backward classes (Ahluwalia, 2016).

Furthermore, to transform ULBs into “self-governing institutions,” laudable innovations were injected by the CAA: wards committees for administrative decision-making in large cities, independent State Election Commission for transparent civic elections, and State Finance Commission for suggesting measures to strengthen municipal finance (Constitution of India, 1950 ss. 243P – 243ZG). Possibly the most important effect of the CAA was that ULBs had an independent right to existence irrespective of political dispensation in power at the state level. States also faced judicial ire whenever they attempted to dissolve a ULB, played foul with their political autonomy, or were hesitant to implement the CAA provisions in letter and spirit (Pranoy Roy v State of West Bengal, W.P. No. 6063(W) of 2015 (Calcutta High Court directed the state to hold local elections within reasonable time); PUCL v State of Nagaland, Civil Appeal No. 3607/2016 (Supreme Court of India asked the state government to implement 33% women reservation in local bodies); Mohansingh Tanwani v State of Maharashtra, AIR 2002 Bom 39 (Bombay High Court quashed the state order that dissolved the Dhule Municipal Council without providing any reasons)).

From a citizen’s perspective, autonomous and independent ULBs represent a quintessential avenue for addressing concerns and are usually the first point of contact to avail government services. Many opinion polls have shown that Indian citizens have comparatively higher trust in their local governments than other elected officials and, thus, are most likely to approach them in times of crisis (Azim Premji University, 2019). This proximity and trust between ULBs and citizens develop a true state-local and citizen action, particularly in times of crisis. Therefore, it is not surprising that policymakers and scholars consider ULBs a vital cog in India’s institutional framework of disaster management (Pal, 2014). The critical role played by ULBs during the COVID-19 pandemic further demonstrates the importance of local governments in disaster response.

In the next section, the role played by municipalities during a disaster will be discussed by highlighting the work done by them during the current pandemic. This will demonstrate the importance of third-tier governments in cities and echo the significance of decentralized governance for disaster management.

COVID-19 and the Role Played by Municipalities in Pandemic Management

An unintended but welcome consequence of the struggle against the pandemic is the acknowledgment by governments that decentralization is critical to successfully preventing, detecting, and managing diseases in urban areas. But without meaningful powers to act autonomously, the third tier of government would fail to maintain the health infrastructure during public health emergencies (Nivedita & Viswanathan, 2021). This realization, however, did not come in the early stages of the pandemic. When the crisis unfolded in March 2020, the central government responded by retaining all powers relating to the management of the pandemic (Kumar, 2020a, b). In the absence of bespoke public health laws, the government resorted to statutes such as the *Disaster Management Act, 2005* (DMA) and *Epidemic Diseases Act, 1897* (EDA) (DMA was written after the Indian Ocean Tsunami and dealt with natural calamities. The expansive definition of the term ‘disaster’ under s. 2(d) of the act allowed the central government to respond to the infectious disease under its ambit. EPA was passed during the British colonial rule in India and was written to contain the plague when the idea of the state was radically different from what it is now). Strikingly, none of these statutes were enacted to deal with public health emergencies (Bhatia, 2020). Multiple guidelines and binding executive directions were invoked under these statutes, sometimes daily, to deal with the changing demands of the pandemic. Under s.10 of the DMA (The Disaster Management Act, 2005 s. 10), the government declared a national lockdown in late March 2020 without consulting the states, despite the fact that the Constitution grants states the power to legislate with respect to public health.

Khorakiwala (2021) argues that such excessive centralization soon had a detrimental effect “across all sectors, leading to confusion, delay in response and a miscalculation of the local response required versus the national and/or state-level response being implemented.” The ensuing migrant crisis laid bare the hollowness of India’s disaster management system. Furthermore, the disempowerment of state and local governments through multiple directions and advisories under DMA and EPA exposed a striking disregard for federal principles by the central government (Shringare & Fernandes, 2020). For instance, in April 2020, the central government directed state governments not to procure Personal Protective Equipment (PPE) and other safety kits as it promised to procure and distribute the kits itself. Many states subsequently experienced a massive shortage of safety kits resulting in many frontline workers testing positive for COVID-19 (Suryawanshi, 2020).

The situation was only rectified after 68 days of nationally mandated lockdowns when states were allowed to manage the pandemic more locally. A few state governments followed the position taken by the central government and centralized pandemic management by invoking s.2A of the EDA (Kaur & Gupta, 2020). Several states, however, immediately enacted regulations under EDA permitting a decentralized response to pandemics through ULBs in cities (For example, Bihar Epidemic Diseases COVID-19 Regulations; Uttar Pradesh Epidemic Diseases COVID-19 Regulations 2020, Delhi Epidemic Diseases COVID-19 Regulations,

2020). Many states also made local governments nodal agencies for coordinating various aspects of pandemic management: information dissemination, managing lockdowns, dealing with vaccine hesitancy, and making provisions for access to basic amenities like food and medicines for vulnerable communities (Aiyer, 2020; Sahoo, 2020). The state of Odisha went a step further and delegated powers of the district collectors under s.51 of the DMA to the heads of local governments to fight the pandemic (Editorial, 2020). Realizing the futility of a centralized approach in pandemic management, the central government also issued a notification, titled the “Micro Plan for Containing Local Transmission of Coronavirus disease (COVID-19),” that placed local governments at the forefront of community mobilization and ensuring active surveillance (Micro Plan for Containing Local Transmission of Coronavirus Disease (COVID-19) <https://www.newindianexpress.com/nation/2020/apr/09/as-per-new-circular-states-depend-on-centre-to-procure-covid-19-medical-equipment-2128010.html>).

With a very high level of citizen’s trust in local governments, the state governments found the delegation of pandemic-related work to ULBs an obvious advantage. Local governments like municipalities soon became the common thread that connected most issues relating to the management and mitigation of the pandemic. In addition to their existing civic duties, ULBs have been entrusted with the task of addressing the migrant labor influx for the last 2 years. This includes offering to workers testing facilities, ensuring that those who tested positive for COVID-19 were in isolation, ensuring the running of community kitchens, and providing monetary support. Essential medical duties were also delegated to ULBs, such as coordinating with the government in contact tracing, organizing health check-ups, and ensuring scientific management of medical transport system and disposal of waste. In addition, local governments have played a leading role in sustaining labor supply and critical food supply chains during the pandemic (Sahoo, 2020).

The work done by ULBs during the pandemic reminded central and state governments of their two distinct strengths of the former. The first is the possession of local-level knowledge which makes them eminently suitable to deal with a grave crisis like the pandemic. Due to ULBs proximity to citizens, it is essential that disaster management frameworks include a level of government that is the first point of contact for most citizens and thus is best placed to know about their mobility, social security, and health needs. For example, one reason for Kerala’s early success in pandemic management was the leadership and coordination effort of local governments to ensure containment of the COVID-19 crisis. ULBs in Kerala ensured that every resident arriving from outside the state during the pandemic were greeted by auxiliary health workers in their house. Then basic information such as their names, travel details, and existing health issues were documented. For the next 14 days, District Coordination Centers called the residents to enquire about their existing and new health issues (Kapur & Panicker, 2020). There is no doubt that such hyper-local coordination efforts and engagement with a community, which is vital for pandemic management, could only be made by institutions like ULBs.

Second, on an administrative front, the effective implementation of the national and state government decisions under the DMA is dependent on the ground-level implementation of such decisions by local governments like ULBs. In India's disaster governance framework, however, the DMA paved a path for the formation of federated statutory agencies at central (National Disaster Management Authority: *s.3*), state (State Disaster Management Authority: *s.14*), and district levels (District Disaster Management Authority: *s.25*). The rigidity of representation in these bodies has significantly limited the participation of local elected representatives in the disaster management committee.

Although a few Indian cities like Mumbai, Pune, Chennai, Jaipur, etc. have a bespoke disaster management cell to deal with emergencies, they are an exception. Most Indian cities have not put in place bespoke governance and structural framework to deal with disasters like the COVID-19 pandemic. Even among the cities with a modicum of disaster management structure in their ULBs, the institutional efficiency and planning are questionable. For example, Mumbai has two District Disaster Management Authorities, one for the city and one for the suburbs. There is also a Greater Mumbai Disaster Management Authority formed in 2011, helmed by municipal commissioners and other essential personnel from police, railways, and other government departments. However, these District Disaster Management Authorities have never held a meeting and have not placed a district disaster management plan in the public domain (Bhide & Kamble, 2020).

The above issues are ironic as ULBs were in constitutional existence long before the enactment of the DMA. The effect of this legal absence of a clear mandate for ULBs in disaster management made the scope for institutional building for disaster mitigation limited. That is why most ULBs lack accessible infrastructure like disaster-resilient offices, personnel, and technology and have limited knowledge of how to blend national disaster management plans with the development plans of cities and towns (Pal, 2014). However, ULBs in the last 2 years, through their active role in pandemic governance, have shown that decentralized governance can effectively overcome a crisis even in the densest and most poorly served urban habitats (Desai, 2021). It became clear that they remain the best bet for providing institutional arrangements during disasters at a constant level.

Undoubtedly, the devolution of powers to ULBs during the pandemic is a positive development and may go a long way in institutionalizing the principle of democratic decentralization in India. However, long-time observers of Indian politics and administration are treading with caution in believing that the pandemic will radically alter the centralizing tendency in state-local government relations (Rajagopalan, 2020). Questions have been raised regarding ULB's institutional capacity to continue with the torrent of duties delegated to them by central and state governments for managing the response to the pandemic (Udas-Mankikar, 2022). This is because even before the pandemic, ULBs in most Indian cities were grappling with severe problems concerning the devolution of powers and stretched municipal finances (Meloche & Vaillancourt, 2015). With cities having the unenviable tasks of executing the ambitious agendas of governments' post-pandemic response, serious introspection must also be made on challenges faced by municipalities during the pandemic.

In the next section, light will be shed on some of those challenges faced by ULBs during the pandemic. The focus is on identifying the structural fault lines and institutional lacunas that plagued ULBs functioning during the pandemic.

Challenges Faced by Municipalities During the Pandemic: Structural Fault Lines Drawn to the Fore

When the COVID-19 pandemic hit India, it was expected that cities and towns would become hotspots and would have significant outbreaks. The concentration of informal settlements combined with social, financial, and environmentally unsustainable development had already put unmanageable pressure on the provision of cities' civic amenities and services (Gore & Gopakumar, 2015). ULBs were already stretched both functionally and financially even before the pandemic. As they could only perform a modicum of their already designated civic functions, doubts were raised regarding their ability to manage the pandemic response. These reservations came to the fore when the central government and state governments after the initial period of centralized pandemic response made local governments nodal bodies for pandemic response in their jurisdictions (Shringare & Fernandes, 2020).

As discussed in the previous section, ULBs across the country did a laudable job in pandemic management despite challenges and were successful in fending off the first wave of the pandemic. However, the fierce intensity of the second wave, which peaked in April and May 2021, exposed deep fissures and fault lines in India's urban capacity to deal with such an unprecedented catastrophe. There were disparities in how urban India sought to combat the pandemic. ULBs' success in response to the pandemic depended "partially on their existing capacity, the devolution of power, and level of trust the state ha[d] traditionally placed on them" (Kapur & Panicker, 2020). ULBs in states that have historically granted political, functional, and financial decentralization of powers to local governments were more successful in managing the crisis. For instance, the common thread between the much-lauded and successful Mumbai-Dharavi and Kerala models of pandemic governance was their reliance on resilient local governments and community participation (Krishnakumar, 2020; Lewis, 2021).

For example, from the initial stages of the pandemic, the urban local government for Mumbai, the Brihanmumbai Municipal Corporations (BMC), focused on building hyper-local pandemic mitigation measures decentralized capacities (Lewis, 2021). Under the overall supervision of the elected leadership, the corporations established ward-level COVID-19 war rooms, which adopted a 360-degree approach to ensure ambulances, ICU beds, uninterrupted oxygen supplies, and all critical medicines. For Dharavi, a heavily congested slum area, the BMC permanently stationed its workers to sanitize public toilets (the most common are of contact and spread of virus) and liaised with community leaders to provide food to residents who had lost their jobs and income (Lewis, 2021). The Mumbai-Dharavi model of aggressive tracking and testing, which was blended with a robust social security net,

soon became a lesson for Global South cities with large, highly congested slum sprawls and was applauded by the World Health Organisation (Awasthi, 2020). The BMC's relative success in managing the crisis was also lauded by the Bombay High Court and the Supreme Court of India. Arguably, the BMC realized the potential of the concept of decentralization and the devolution of powers as envisaged in the CAA.

A similar decentralized governance structure for pandemic management was found in Kerala. The state government mobilized its vast army of volunteers with the aid of local governments to monitor every aspect of pandemic mitigation. For example, while the majority of states in India scrambled to manage the mass movement of migrant workers and to avert a humanitarian disaster, Kerala leveraged its local government to take care of its informal workers by providing food and basic amenities, setting up community kitchens, collecting information on workers, and opening relief camps (Vora, 2020). However, barring these islands of excellence, the majority of ULBs in the country struggled in their pandemic management. The difference can be gauged by comparing the experience of ULBs in Delhi, which saw an unprecedented crisis in its services, despite being situated in the national capital with access to excellent health infrastructure and direct support from the central government.

When the pandemic peaked across India in April–May 2021, Delhi witnessed an average of 28,000 daily cases. In fact, it was among the region that had recorded some of the highest reported deaths in the country. Although the impact of the second wave of the pandemic was devastating across the country, Delhi's problem got exacerbated because of its complex governance structure (Kumar et al., 2021). To begin with, Delhi has a multiplicity of overlapping sub-national jurisdictions delivering health functions, including the Delhi government, New Delhi Municipal Council, three municipal corporations of Delhi, and the Cantonment Board. There was constant power struggle between these bodies during the pandemic – a phenomenon referred to as “conflictual federalism” (Sahoo, 2020). For example, the three municipal corporations of Delhi, which became the fulcrum of pandemic management in the national capital, saw an unprecedented shortage of essential medical supplies, staff, and hospital beds due to exploding cases and a lack of coordination between ULBs and government. The increased demand for hospital and ICU beds, oxygen, and essential drugs laid bare the unpreparedness of the government machinery to deal with the unprecedented challenges posed by COVID-19 (Kumar et al., 2021). Soon, ward afterward started reporting stories of death and despair. The situation was so dire that the Supreme Court of India, in a rare intervention in policy issues during the COVID-19 pandemic, reprimanded ULBs in Delhi for their abject failures in controlling the pandemic (In Re: Cognizance for Extension of Limitation Suo Moto Writ Petition (Civil) No. 3 of 2021). Similar stories of despair were reported from various ULBs across the country (Ara, 2021).

Another crisis that grappled ULBs was the deterioration of their finances due to the pandemic, impacting their ability to provide services to local communities (Dugal, 2021). To understand the impact on India's ULBs, the Reserve Bank of India (RBI) conducted an online qualitative survey of 141 municipal corporations

between July and August 2021. The analysis found fiscal stress built up across these entities, with revenue falling and expenditure rising, forcing cutbacks across non-essential categories (Dugal, 2021). Several municipal corporations had to cut expenditures in other areas to make funds available for the Covid-19 response. They mobilized additional funding from grants (from states and the center), reserves, borrowing, municipal funds, donations, and contributions, which amplified their structural constraints of raising money (Ali, 2021). This is when the responsibilities of local governments towards the delivery of civic functions had increased considerably. There is no doubt that these additional expenditures will force ULBs to cut down their development spending and use their reserves and other contingency funds.

When viewed through the lens of constitutional law, these disparities in ULB's response to the pandemic can be attributed to factors, such as lack of devolution and decentralization of powers and lack of finances. In a way, the pandemic has revived awareness of an issue that never really went away – the fact that since coming into constitutional existence, the progress towards decentralization and autonomy for ULBs has been painfully slowed due to numerous systematic bottlenecks and institutional challenges (Corbridge et al., 2012; Panagariya, 2014). This is mainly because ULBs in India maintain their presence only as administrative units (with separate municipal acts, election commissions, planning committees, and finance commission) and are not able to operate as independent urban institutions due to the lack of funds and functions devolved to these bodies. Moreover, there is no uniformity in this regard across the country, as states have resorted to varying levels of decentralization and devolution of powers to ULBs.

According to the *Devolution Report* (2016), published by the Ministry of Panchayati Raj, Government of India, certain states such as Kerala, Maharashtra, and Karnataka have transferred relatively more powers to local bodies. Kerala leads by example with the *Kerala Municipalities Act, 1994*, which creates ward committees with detailed provisions for their formation, functioning, and facilitation of community participation (Kerala Municipalities Act, 1994 s. 42). The state has also transferred as many as 26 departments to ULBs. Karnataka and Maharashtra have adopted similar decentralized governance mechanisms by creating ward committees in cities like Bengaluru and Mumbai (Kaur & Gupta, 2020). The former has also delegated 17 functions to ULBs under s.243W of the constitution (Nivedita & Viswanathan, 2021). The common theme running across these states is conferring ULBs with exclusive power to administer certain matters, including the running of dispensaries and public health centers.

In hindsight, these delegations of power proved to be visionary as ULBs of these states were in a comparatively better position to tackle the pandemic than their counterparts in other states. Another innovation of CAA that helped ULBs of these states in their work during the pandemic was the presence of District Planning Committees (Constitution of India 1950 s. 243ZD). During the pandemic, these committees effectively coordinated between rural and urban centers for patient transfers, notifying the availability of beds and maintaining the supply chain for the transport of life-saving drugs from one district region to another. The Devolution

Report (2016) suggests that most states either have not formed a committee or have failed to prepare integrated plans. Moreover, real decentralization has a long way to go in India, with several states having transferred as few as three functions to ULBs. So, it should not come as a surprise that ULBs in states like Kerala and Maharashtra were more successful in pandemic management than others.

Furthermore, when it comes to ULB's fiscal devolution, autonomy, and functions, the situation is damning. The State of Municipal Finances in India (2019) report shows the precarious financial health of Indian urban local bodies, with a majority of them not having enough money to pay the salaries of their staff or perform basic civic functions. There can be two main reasons for this. First, most local bodies cannot generate enough funds from their internal sources due to limited capacity to impose taxation on their subjects (The High-Powered Expert Committee for Estimating the Investment Requirements for Urban Infrastructure Services, 2011). This makes them heavily reliant on the devolution of funds from the central and state governments in the form of transfer and grants, making them unable to embark on development activities independently. The second reason is the lack of delegation of adequate financial powers to ULBs by state governments. The power to determine the revenue base for local bodies lies with state governments, which over the years have only permitted ULBs to collect property taxes or water tariffs, but not land zoning, which can unlock substantial revenue (IDR, 2020). Even the property tax, which is the largest source of revenue, is not enforced correctly due to ambiguous taxation norms, lack of reliable records, archaic assessing systems, and state interference in property tax rates (Atreya, 2020).

In addition to this, there is a disparity in state approaches to municipal finances. States like Kerala have devolved 35% of state's development budget to local governments so that communities can define and implement their developmental priorities. The state government even allows the professional tax proceeds to go to local bodies that can invest them in priority areas like health and education (Sharma & Visakha, 2020). Similarly, ULBs in Karnataka are allowed to independently raise funds under the *Karnataka Municipal Corporations Act, 1976* (KMC). The new *Bruhat Bengaluru Mahanagara Palike Act, 2020*, which replaces the KMC's provisions for governing Bengaluru, further increases the taxation powers of the Corporations by allowing them to impose taxes on professions and entertainment (*Bruhat Bengaluru Mahanagara Palike Act, 2020* s. 142). When the pandemic struck in these states, ULBs could mobilize resources quickly for pandemic mitigation. This was in stark contrast to ULBs in states like Uttar Pradesh, Uttarakhand, Bihar, Jharkhand, Rajasthan, and Haryana, where due to poor financial conditions ULBs could not even provide basic services during the pandemic (State of Municipal Finances in India 2019). As a result, these states suffered a devastatingly high fatality rate during the pandemic's second wave in India.

The structural and institutional fault lines of ULBs exposed during the pandemic should not have come as a surprise. In every decade of their constitutional existence, the recurring themes in criticism of urban governance in India have been the same, i.e., there is a lack of financial devolution and autonomy for ULBs, and that cities are only politically decentralized but not functionally so (De souza, 2003; Oomen, 2014). Even

after 30 years, state governments' institutional inertia and apathy toward ULBs remain unchanged. This is despite ULBs having acquired a host of new responsibilities over this period, including city development planning, city mobility planning, city sanitation planning, e-governance planning, and now pandemic mitigation planning. Ahluwalia (2019) rightly notes that to address the challenges of urbanization in India, "state governments have an important role to play not only in transferring functions, funds, and functionaries but also in providing an enabling environment through legislative and institutional reform." In hindsight, municipal governments lack agency in their relationship with state governments, which renders them institutionally disempowered.

The following section will discuss how ULBs lack agency regarding their functions and finances in their relationship with state governments, which ultimately affects their day-to-day functioning. The focus will be on identifying structural changes through which agency could be granted to ULBs in their administrative and financial relationships with state governments.

Need for Granting Agency to Local Governments: A Key Lesson Learnt from ULB's Pandemic Management in India

The pandemic management by various levels of government in India has made it amply clear that the core problem faced by the Indian republic during an evolving crisis like a pandemic is its highly centripetal governance structure. Ideally, disasters like the COVID-19 pandemic need to be tackled in a highly decentralized manner – at the city, village, and block level supported by institutions that are not merely constitutional but also functionally empowered. Nevertheless, the elected representatives at the helm of these institutions do not have the functions and finances to deliver good governance. Rajagopalan (2020) notes that "local governance has four constitutional aspects – form, functionaries, function, and finances. India has done a great job with the former two, but not the latter."

Generally, the blame for such dysfunctional institutions, sometimes rightly, can be traced back to the nation's founders, who had failed to create a constitutionally mandated local government. However, as discussed earlier in this chapter, this deficiency has been corrected through the enactment of the CAA in 1992. In reality, the CAA has only provided constitutional recognition to ULBs but has not empowered them to do their functions in the letter and spirit of the legislation. The reason for the latter can be attributed to a fundamental but deliberate error on the part of political leaders when the CAA was enacted. Through the usage of the term "shall" in some places and "may" in others in the CAA, the legislators left the extent of devolution of functions and empowerment of these bodies at the discretion of states. Such discretionary delegation of the subject matter ended up in a whole array of interpretations that suited the immediate needs of states (Jha, 2020a, b). For example, the Act indicated that there should be a clear demarcation between Nagar panchayats, municipal councils, and municipal corporations in towns and cities (Constitution of India 1950, art. 243Q). Such demarcation should be based on the

region's population, demographic density, revenue, and non-agricultural activities. In reality, states have not followed any semblance of uniformity when making these delineations. Large settlements are still termed villages, and smaller towns have been upgraded to cities. Critics have argued that such considerations are because of reluctance on the part of rural political leaders to accept the municipalization of villages due to perceived loss of power and revenue (Jha, 2020a, b).

Naturally, this has caused structural and functional problems in ULBs because state governments' decisions have been driven by political expediency rather than considerations of good governance. Recognizing the detrimental effect of the discretion given to states in determining functions of ULBs, both the National Commission to Review the Working of the Constitution (2002) and Second Administrative Reforms Commission (2007) have recommended amendments to the Constitution to tweak ULBs constitutional design. The amendment should provide that state legislatures shall, by law, mandatorily vest ULBs with such powers and authorities that enable them to function as institutions of self-government. However, without this change, ULBs have been tied to state governments' discretionary interpretation of various provisions of the CAA. It would be safe to conclude that ULBs have no decision-making powers concerning their working with state governments, hence the usage of the term "lack of agency." This is generally reflected in ULB's administrative and financial relationships with state governments.

- **Lack of agency in administrative relationship with state government:** There is no doubt that the failure of state governments to spell out a well-defined functional domain for ULBs has led to challenges in governance and a lack of autonomy for ULBs in Indian cities. However, beyond this structural fault in ULB design, the pivotal reason for the lack of agency of cities and towns in their administrative relationship with states is the presence of parastatals (A parastatal is a state-owned company with a distinct legal form, generally created to undertake a city function such as water supply, city transport or urban planning). These governmental agencies were initially set up on the recommendation of international organizations to perform functions generally reserved for municipal governments, such as slum development, water delivery, housing, and other essential civic functions (Jha, 2020a, b). Due to the limited capacities of urban governments in cities after independence, the parastatals run by experienced bureaucrats supplemented the capacity of municipal bodies. Over time, irrespective of the rising capacity of ULBs in cities, parastatals got institutionalized. For instance, in cities like Bengaluru and Mumbai, there is an agglomeration of agencies carrying out specialized functions despite some of the best run ULBs of the country overseeing the city's civic functions (For example, in Bengaluru, Bengaluru Development Authority is responsible for land regulation and the Karnataka Slum Clearance Board is responsible for slum rehabilitation. In Mumbai, development work is undertaken by Municipal Corporations of Greater Mumbai and Metropolitan Regional Development Authority).

Such a polycentric governance system creates multiple challenges for the administration of cities, including wastage of resources and overlapping functions

with ULBs (Pethe et al., 2011). As parastatals are not only managed by state governments but also accountable to them, their intrusion into ULB's functional domain leads to erosion of autonomy for the ULBs. Most importantly, it challenges the authority and accountability of ULBs. If the third tier of government has no authority over its functions and instead its powers are vested in officials appointed by the State government, then local governance would be reduced to mere symbolism. This lack of agency was widely seen during the pandemic when many ULBs across the country were hard-pressed to do functions that they had systematically been deprived of in the pre-pandemic era. It is high time that certain functions are made exclusively the domain of ULBs and those that need to be shared with state governments be specified for resolving this agency problem. Experts have also "recommended that the municipality be responsible for providing civic amenities in its jurisdiction and if a parastatal exercises a civic function, it should be accountable to the municipality" (Second Administrative Reforms Commission, 2007).

- **Lack of agency in financial relationship with state government:** In the financial domain, Indian ULBs are among the weakest globally, with municipal revenue accounting for just one percent of the GDP in 2017–2018 (Indian Council for Research on International Economic Relations, 2019). As discussed in the previous section, a triple whammy of the low tax base, lack of capacity to raise revenue, and an obdurate state government that limited effective devolution of revenue to ULBs have contributed to the financial apathy of ULBs. Even the structural innovations of the CAA, like the establishment of State Finance Commissions, have failed to bring certainty, clarity, and consolidations in the transfer of revenue to ULBs (Report of the Working Group on Urban Governance 2018). Although the Fifteenth Finance Commissions for 2020–2021 recommended Rs 90,000 crore in grants for local bodies, such a massive transfer of resources does not resolve the fundamental problems underpinning ULB's financial relationship with states.

ULBs are never part of financial negotiations between states and central government when done under the auspices of constitutional or supra-constitutional bodies like the Finance Commission and NITI-Aayog. For example, in the last decade, India's political class traversed the political divide to create a new indirect taxation regime called Goods and Services Tax (GST) in India. During the negotiation, state governments had little inclination to devolve even a small part of the revenue from GST to the third tier of government (Ahluwalia et al., 2014). This was so even after the proposal for the GST (which subsequently did materialize) to subsume all local taxes, including Octroi, advertisement, etc. This has left many municipalities financially weaker than before, relying on government grants for performing their mandates. Therefore, it is unsurprising that ULBs struggled to provide essential services during the pandemic.

It is evident from the discussion above that there is a clear case for raising the financial autonomy and reforms of municipal finances to provide better public services to citizens. Apart from the reform needed in the structural relationship of ULB's fiscal devolution, autonomy, and functions vis-à-vis state government,

ULBs must also become serious about augmenting their revenue through various resources and stop the temptation of fiscal slippages that routinely occur in their budget. RBI's (2021) latest state finance report showed that 30 to 35 percent of the 221 ULBs surveyed are severely stressed fiscally, and more than 50 percent of them have reported declining revenue. A significant reason for this precarious fiscal position remains the structural issues, i.e., low diversification of ULBs tax resources on account of the non-devolution of subject matters by the state government to ULBs. However, the RBI's study also shows that the ULBs are increasingly committing a higher expenditure than their revenue receipts, making them increasingly dependent on grant-in aids and transfer of funds from upper tiers of the government for their routine functions.

A host of reforms have been recommended by constitutional and statutory bodies like the Finance Commission and Securities and Exchange Board of India (SEBI), taking note of the fiscal imprudence of ULBs and the need to augment internal resources of ULBs. For example, the 15th Finance Commission has recommended two entry-level conditions for ULBs to access the increased grant recommended by it, i.e., notifying the floor or minimum rates of property tax to improve internal revenues and timely submission of audited accounts. To augment the internal revenue of ULBs, SEBI also has relaxed norms for "Issue and Listing of Debt Securities by Municipalities (commonly known as MUNI bonds), which allows ULBs to raise capital from the securities market. Implementing the National Municipal Accounts Manual (NMAM) to ensure correct, complete, and timely recording of municipal transactions is another major initiative to increase fiscal and reporting transparency among ULBs in India. RBI (2021) report has further outlined a series of reforms like revitalizing the municipal bond market, boosting developmental/infrastructure finance and green finance, and exploiting land-based financing opportunities for self-sufficiency of ULBs in India. Going forward, it is imperative that reforms in devolution and financial autonomy for ULBs must be done in conjunction with the strengthening of ULB's governance structure and empowering them to raise their resources.

Conclusion

The COVID-19 pandemic has highlighted the importance of reimagining urban governance by taking efficient preventive and risk-mitigating measures and building systemic resilience in our cities. In India, this reflection could be done by going back to the drawing board to tweak the constitutional design of ULBs to make them functionally and financially empowered. The fissures that emerged in ULB pandemic management are a timely reminder that India's urban agglomerations should rely on decentralization and devolution of functional and financial governance for creating solid cities and towns.

Abstract

Waterlogging is a long-duration slow-onset disaster and experienced in many parts of Bangladesh. Several areas in the eastern and western coastal zone suffer from extensive and permanent waterlogging. The southwestern region, with a population of 40 million, is experiencing persistent waterlogging for 2 to 6 months each year for the last 30 or more years. This can be attributed to its geographical location, polderization, death of upstream rivers, hydro-morphological changes, siltation in rivers, encroachment of riverbanks, illegal structures, and unplanned aquaculture. More than a million people are seriously affected each year. Disaster risk through waterlogging is expected to become worse because of sea-level rise, increased precipitation with the changing climate, subsidence inside polders, and sedimentation of peripheral rivers. Prevention strategies include policy and institutional interventions, relief and rehabilitation, and infrastructural measures. Seven infrastructural measures have been proposed: construction of the Ganges barrage, maintenance dredging of the Gorai River, tidal river management, pumping and drainage improvement, revitalization of regional rivers, adaptive land use, and depolderization. Tidal river management (TRM), a locally grown concept, is widely appreciated as one of nature-based solutions but is found to have implementation complexities. Many programs and projects have been undertaken. Overall results have remained mixed, despite increased budgetary resource allocations.

Keywords

Waterlogging · Disaster · Climate change · Tidal river management · Polderization

Introduction

Bangladesh is one of the most disaster-prone countries in the world. The country is also impacted by global climate change. Prevention for risk reduction from natural and climate related disasters is seen as prerequisite as Bangladesh is transitioning from a lower- to a middle-income country. This chapter focuses on one of the natural disasters, waterlogging in Bangladesh.

The aims of this chapter are to elaborate on:

- (a) Nature, extent, and causes of waterlogging in general but focusing on the southwestern region
- (b) Plans and programs undertaken to prevent waterlogging
- (c) The success or failures of implemented programs

This chapter is based mostly on literature review, analysis of secondary data, field visits, and interaction with waterlogged communities.

Bangladesh and Waterlogging

Bangladesh has a tropical monsoon climate with an annual average rainfall of 2200 mm. Over 60% of annual rainfall occurs in 4 months (May to August). During this period, Bangladesh often experiences extreme flooding. Waterlogging is also experienced in many parts of the country, specially within the polders of the coastal zone. Polders are lowlands encircled by dykes or embankments to prevent tidal flooding and salinity intrusion. Polders, in recent times, have been blamed for causing waterlogging.

Definitions and types of waterlogging vary. Technically, waterlogging is a situation when groundwater level touches plants' root zone. Waterlogging, in general, is a form of flooding within embankments where water stays stagnant on ground for any period up to 6 months.

There are at least three types of waterlogging experienced in Bangladesh: urban, rural, and coastal.

Urban waterlogging occurs due to increased built up areas, intense rainfall over a short period of time, and inadequate capacity of drainage networks resulting in increased runoff. All major cities of Bangladesh including Dhaka, Chattogram, Sylhet, Khulna, Pabna, Tangail, Jashore, and Cox's Bazar (Subrina & Chowdhury, 2018; Rahaman et al., 2020) experience waterlogging. Urban waterlogging is short-lived, from a few hours to even 2 weeks. In Dhaka, loss of wetlands and floodplains has also aggravated the problem.

Rural waterlogging occurs during high rainfall events coupled with high water levels of the surrounding rivers. In rural areas, roads, embankments, and other infrastructure are constructed without adequate drainage provision. Waterways are also getting silted up and often encroached upon.

In contrast, **coastal waterlogging** is a slow-onset predictable disaster, happening every year for 2 to 6 months. In the southeast coast especially in Noakhali district, over the past decades, both natural and man-made land reclamation have occurred. This has elongated drainage path and lowered drainage gradient causing waterlogging in the area. In contrast in the south west coast especially in Satkhira, Jashore, Khulna, and Bagerhat districts, waterlogging is mainly due to polderization. The coastal zone of Bangladesh is mostly poldered (embanked) and has disturbed and altered hydro-morphological setting.

Waterlogging is causing huge **economic losses** (BBS, 2016; Quddusi, 2017). During the 2009–2014 period, waterlogging caused US\$ 31 million in property damages yearly (BBS, 2016) which, if prevented, could have the GDP volume increased by 0.02% per year. In 2017 alone, Chattogram, the port and industrial city, suffered economic damages of US\$ 71 million (Quddusi, 2017).

After brief introduction of definition, types, and economic losses, this paper elaborates on waterlogging in the southwest region of Bangladesh identifying areas, root causes, extent, socioeconomic impacts, and expected impacts of climate change; following through prevention strategies in terms of regulatory and institutional interventions, relief and rehabilitation, and projects and programs; and concluding with a discussion on successes and failures.

Waterlogging in the Southwest Region of Bangladesh

The southwest region has several morphologically active tidal rivers. They are the main drainage network for coastal polders and low-lying depressed areas (beels). Huge quantity of silt is deposited into the river system as tide flows in from the sea. On the other hand, freshwater flows from the upper Ganges system help to flush the sediment, and thus, drainage capacity of tidal rivers is maintained naturally. In the early 1960s and 1970s, this natural process was disrupted substantially after polderization. Coastal polders prevented sedimentation on the low-lying lands but caused sedimentation in the peripheral rivers of polders. In addition, these tidal rivers received increased sedimentation due to reduced dry season freshwater flow caused by withdrawal of water upstream.

Causes of Waterlogging

Many authors have identified causes of waterlogging in the southwest region. These can be summarized as polderization, hydro-morphological changes in tidal river system, death of upstream rivers (e.g., Mathabhangha River), siltation and encroachment of rivers, poorly executed infrastructures, road networks inside polders, illegal structures, unplanned aquaculture, low topographic slope, and sea-level rise (FAO, 2015; Awal & Islam, 2020; Tahsin et al., 2020).

The Food and Agriculture Organization (FAO, 2015) also indicated that institutional bottlenecks are as equally important to cause waterlogging. Institutions are weak to manage water-related infrastructure, including uncoordinated canal excavations by various agencies, unlawful permission to build aquaculture ponds on natural canals, and operation and maintenance (O&M) of sluice gates.

Extent

Many studies have elaborated and reviewed the extent of waterlogging in southwest Bangladesh (FAO, 2015; Tareq et al., 2018; Awal & Islam, 2020). Satkhira, Jashore, Khulna, and Bagerhat districts have routinely experienced localized and prolonged waterlogging during the annual monsoon season. FAO (2015) has mapped waterlogged areas in eight Upazilas (subdistricts) using satellite images and ground truthing (Fig. 1) indicating different extent in different years.

Tareq et al. (2018), using Landsat TM images for the years 1989, 2000, and 2011, revealed that waterlogged area in Tala Upazila has increased from 0.7% in 1989 to 34% in 2011. There was an increase in 63% of water bodies during 1989–2000, which expanded to 77% during 2000–2011.

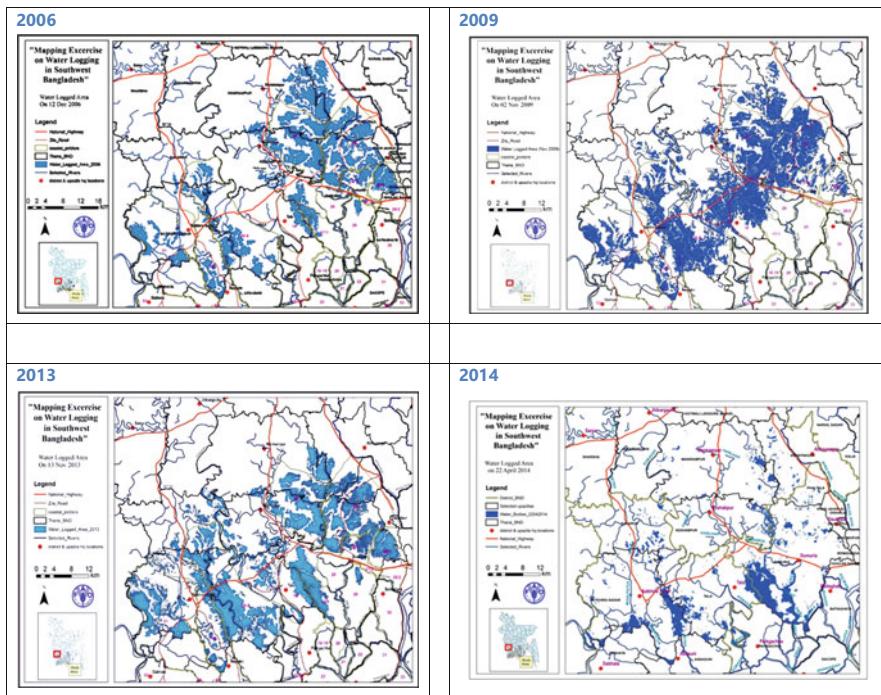

Fig. 1 Mapping of waterlogged areas in the southwest region in different years (FAO, 2015)

Implications: Poverty Pockets

More than one million people were seriously affected due to waterlogging in 2011 and 1.3 million in 2016 (Awal & Islam, 2020). Islam et al. (2020) found that waterlogging impacts livelihood including crop failure and damage, disruption in coping mechanism, physical and mental illnesses, loss of income, and increasing level of debt.

The effects of waterlogging are loss of property, lack of access to essential services (such as water and food), and damage to infrastructure. At the homestead level, the impacts are the loss of shelter, less access to safe food and water, and loss of basic services such as health and education. Women and children are becoming more vulnerable due to increased frequency and extent of waterlogging. Some areas, in fact, are new ecologically vulnerable poverty pockets.

In waterlogged areas, people are adapting (Shaibur et al., 2019) to various alternatives. For example:

- Moving temporarily or permanently to other places
- Modifying their bamboo or cottage-type houses to tin-shed or semi-brick type
- Changing food habit from cooked food (rice and fish) to dry food (flattened or puffed rice)
- Changing profession from farmer to rickshaw or van puller in nearby towns
- Practicing floating, mixed, hanging, or shifting agriculture

Climate Change and Sea-Level Rise (SLR) to Worsen Waterlogging

Waterlogging is expected to become worse because of the joint effects of sea-level rise and increased precipitation in the changing climate, subsidence inside polders, and sedimentation of peripheral rivers (Sarkar et al., 2021). Haider et al. (2021) have shown, using long-term satellite images and applying numerical model, that certain areas will be completely waterlogged in an end-of-century scenario.

Bangladesh ranks 164 out of 180 countries in 2019 (ND-GAIN, 2022) in the Notre Dame Global Adaptation Index (ND-GAIN). Bangladesh is the 26th most vulnerable country and the 24th least ready country. This means Bangladesh is vulnerable to climate change but not ready to combat its effects.

Prevention Strategies for Risk Reduction to Waterlogging

Strategies for prevention can be described through three aspects: (a) institutional and policy interventions, (b) relief and rehabilitation, and (c) structural/physical interventions (projects and programs).

Institutional, Policy, and Regulatory Framework

Many government and nongovernmental agencies have direct and indirect roles, but lack of coordination among agencies has been identified as the main institutional bottleneck. These institutions tend to work only within its own areas of competence, within its own comfort zone. Institutions have their own understanding of the nature and complexities of the waterlogging problem. They lack understanding of interdisciplinary solutions accommodating environmental, social, and economic considerations. The Programming Division of the Bangladesh Planning Commission and the UNDP has proposed a coordination mechanism between and among different institutional stakeholders to address waterlogging in three districts (PD/BPC and UNDP, 2018). However, the proposal is yet to be implemented.

Bangladesh's regulatory framework for disaster management comprises of the relevant legislative, policy, and best practices. The framework includes the following:

- Disaster Management Act 2012
- National Disaster Management Policy, 2015
- Disaster Management (Committee Formations and Functions) Rules, 2015
- Standing Order on Disaster, 2019
- National Plan for Disaster Management, 2021–2025, 2021
- Disaster Management (Fund Management) Rules, 2021
- Guidelines at all levels as best practice models

As per the Disaster Management Act 2012, persistent waterlogging is considered as one of the natural disasters. In September 2015, the government of Bangladesh (GoB) has adopted the Disaster Management Policy. Policies for reducing risk from waterlogging are identifying waterlogged risk areas and affected communities, adopting long-term plan, devising modern early flood warning system, and re-excavating rivers and canals.

Translating the Disaster Management Policy, the eighth FYP (Five-Year Plan: 2021–2025) of the government of Bangladesh emphasizes on the implementation of the Bangladesh Delta Plan for better management of natural disaster incidence including waterlogging. The target of the eighth FYP is to reduce waterlogging from existing 2.5% to 0.25% of the coastal area and to reduce persons vulnerable to waterlogging from 0.9 to 0.1 million by 2025.

Relief and Rehabilitation

To support poor and marginal communities, the government has established the safety net programs that include funds for Food for Work (Kabikha), Test Relief (TR), 100-day employment generation scheme, Vulnerable Group Feeding (VGF), and Vulnerable Group Development (VGD). Some of these funds are spent on activities that are relevant to waterlogging. For example, food is distributed through the VGF scheme to waterlog-affected communities, which help build resilience. The 100-day employment generation scheme reduces economic vulnerability through job opportunities and income generation for waterlogged communities. Some of the SSNP (social safety net programs) funds are also spent on activities relevant to water management/waterlogging. The government and NGOs initiate relief efforts in the waterlog-affected communities.

Structural/Physical Interventions

To address waterlogging in the southwest region, the Bangladesh Delta Plan 2100 (GED, 2018), a long-term integrated and holistic plan, has proposed seven infrastructural measures: (a) construction of the Ganges barrage to improve drainage capacity of regional rivers; (b) maintenance dredging of the Gorai River, the main freshwater source; (c) tidal river management (TRM); (d) mechanical pumping of

waterlogged areas; (e) revitalization of regional rivers; (f) aquaculture in waterlogged areas; and (g) depolderization (removal of dykes) of certain polders.

While all these measures have certain merits and demerits, some are also cost-prohibitive. Of these, the TRM process is an example of building with nature and a resilient measure for waterlogging, river sedimentation management, and subsidence. TRM can be applied in a cyclic way, though not all areas are suitable. Tidal river management could become standard procedure for coastal polders. This would counterbalance subsidence and reduce the problem of waterlogging. Reinhard et al. (2022) have found that pumped drainage, through cooperative investment, increases farmers' income in waterlogged areas.

Tidal river management (TRM) allows natural movement of tide from the river to an embanked low-lying area through a link channel. During flood tide, sediment-laden water enters to the low-lying area where the sediments are deposited due to reduced velocity and long duration of storage. During ebb tide the tidal water flows out of the low-lying area with reduced sediment load and erodes the riverbed and bank at the downstream. The natural movement of flood and ebb tide in the river and low-lying area increases the drainage capacity/conveyance of the river through scouring and supports the river navigability. Deposited silt raises the low-lying area considerably.

Projects and Programs

The Programming Division-Bangladesh Planning Commission and UNDP (2018) has undertaken an analysis of projects and programs implemented in three waterlog-affected districts. There were 352 projects implemented over the past 15 financial years. The number of projects, relevant directly or indirectly to waterlogging, in the 3 districts was estimated as 135, the average number being 9 each year. The GoB is continuing routinely to implement projects/programs under the Annual Development Plan (ADP).

An analysis of resource allocations and budgets (PD/BPC and UNDP, 2018) in three districts (Khulna, Satkhira and Jessore) shows a positive picture. The ADP expenditure has increased in real terms since 2001/2002.

- The government has spent 15% of total allocations in waterlogging-relevant projects. The overall ADP budget was US\$ 1.64 billion at current prices.
- The budget has grown at 10.7% in 2015/2016 over 2001/2002 at current prices, which has exceeded inflation rate. Thus, there is a real growth.

Success and Failures

Of the seven strategic structural/physical interventions to prevent waterlogging described above, five – maintenance dredging of the Gorai River, tidal river management, pump and drainage improvement, revitalization of regional river, and land

use adaptation – have been and still are being implemented. The IMED (Implementation Monitoring and Evaluation Division) of the Bangladesh Planning Commission routinely evaluates and prepares in-depth reports (IMED/PC, 2022). On the Gorai River Dredging and Bank Protection Project, the IMED has noted the upward trend of water flow and decreased salinity in the dry season but emphasized on regular maintenance dredging to sustain results. On the drainage improvement of upper Bhadra River, Horihar River, Buri-Bhadra River, and adjacent khals in Manirampur and Keshabpur Upazila, Jashore (2018–2021), the IMED has noted improved flow of water and reduced waterlogging but recommended deployment of permanent workforce for O&M and TRM management in certain beel areas. On the Southwest Area Integrated Water Resources Planning and Management Project, the IMED has noted increased crop production but declined fish production. This decline is, however, mitigated with increased production through culture fisheries.

Hence, results have remained mixed. However, the tidal river management (TRM) is appearing as one important nature-based solution to reduce waterlogging. Uttaran (2013) has documented process of conceptual development of the TRM as a local, people-centered innovative approach to remove sedimentation through letting sediment to settle in the beels. Seijger et al. (2019) revealed that tidal river management is quite different (local, natural, complex) from mainstream engineering strategies. They concluded that tidal river management has strategic potential, though is hardly recognized in master plans. Bangladesh Delta Plan 2100 supports the concept of TRM but did not propose any new project beyond the current portfolio (Nicholls et al. 2020).

Many studies have found initial successes but recorded challenges due to lack of proper compensation plan, bitter experiences from TRM officials, conflicts within project-affected people, equity issues, improper management, overextended duration of TRM, political reasons, etc. (FAO, 2015; Mutahara et al., 2019; Lázár et al., 2020).

Lázár et al. (2020) have applied Delta Dynamic Integrated Emulator Model (Δ DIEM) to explore the outcomes of four contrasting and plausible development trajectories under different climate and socioeconomic scenarios to the end of the century. TRM has the potential for increased environmental and economic sustainability. The coastal zone can remain habitable and agriculturally productive until 2100 at least if the potential of the TRM can be fully exploited.

Conclusion

More than a million people are affected annually by waterlogging in Bangladesh, particularly in the southwest region. This is continuing for the last 30 years or more. As Bangladesh is aiming to navigate as one of the middle-income countries, it has set in its eighth Five-Year Plan to reduce waterlogged area from existing 2.5% to 0.25%. This is an ambitious target, but efforts are already underway to implement projects and programs, and budgetary allocations have been increasing gradually. However, routine efforts are not seen as adequate as impacts of climate change and sea-level

rise are making the waterlogging situation worse. Hence, while infrastructural measures are implemented, efforts also needed to be placed on institutional coordination. Waterlogging, a recognized long-duration disaster, in Bangladesh is preventable and manageable.

Abstract

Since primitive times, humans are trying to establish harmonious relationship with nature, and it has always been a constant struggle which speaks volumes

M. Sharma (✉)

about the survival and adapting techniques of the species. In last few years, it has been observed that frequency of natural disasters has increased manifold and we humans are collectively liable for this blatant interference with nature which has caused mammoth loss of lives and material over the centuries. In the region of Jammu and Kashmir, various kinds of disasters have been a recurring phenomenon affecting human lives and devastating the economies. The union territory (UT) of Jammu and Kashmir is the northernmost region of India and is considered to be one of the most picturesque lands on the planet. But the region has been unfortunately plagued by various natural disasters ranging from earthquakes, destructive floods, snow blizzards, avalanches, landslides, to wind storms, all owing to its peculiar topography, rugged terrain, extreme weather conditions, and unique geographical and geo-climatic settings, which has always caused a huge loss of human lives and property. This chapter attempts to chronologically trace the major disasters of Jammu and Kashmir region and understand the role of government in mitigating the disasters. This study critically examines the various policy documents, orders, and by-laws which have been framed and implemented from time to time by the government of the day. The study also looks into the role of various government agencies, i.e., National Disaster Response Force and State Disaster Response Force (SDRF), and other associated government departments.

Introduction

We have only experienced terrible calamities with human impact on a scale never previously witnessed in recorded history during the first half of the twenty-first century (Kunstler, 2007).

These include December 26, 2004, tsunami in Indian Ocean, which, despite impacting much less developed coastal countries around the world, killed 283,106 people, and the Hurricane Katrina flooding, which claimed over 3,000 lives across all nationalities (Morris, 2012). More people were at risk as a result of the hurricane's winds destroying a major area of the southern part of United States, which had undergone extensive coastal expansion in past few decades, than the once isolated barrier-island settings (Bush et al., 1996). Humans are ultimately at the mercy of nature, despite emergency management and disaster preparedness efforts to reduce loss of property and human lives by advance planning and public policy intended to prevent individuals from putting themselves in unnecessary danger. Disasters, both natural and man-made, have been more frequent during the past century (Smith, 2013).

Due to its varied geo-climate, the Indian subcontinent is susceptible to a variety of natural disasters. Every year, India has a number of significant natural catastrophes that affect millions of people, especially in isolated communities, and cause

hundreds of fatalities. Natural disasters are still a significant hazard to everyone on Earth, and they might have considerably severe consequences for property and human life (Aini & Fakhrul-Razi, 2010). A sharp reminder of the link between weak governance and human casualties has been provided by severe natural disasters. Natural and human disasters have an especially devastating impact on emerging economies. For instance, the tsunami of 2004 claimed the lives of 227,898 people, primarily in three economically developing but politically volatile countries: India, Indonesia, and Sri Lanka. Similar to this, Haiti earthquake in 2010 affected close to three million people and killed between 46,190 and 316,000 people (Pal, 2021).

Part I

Disasters in Jammu and Kashmir

The severe climate and topography of union territory (UT) of Jammu and Kashmir have made it particularly vulnerable and prone to many natural calamities. Devastating earthquakes, catastrophic avalanches, massive floods, and numerous landslides have all occurred in the area (SDMP, 2017). A series of catastrophic events have devastated the region, including the damage brought on by the 2014 floods, the landslides and flash floods in 2010, and the earthquake in 2005 (Gupta et al., 2012). Jammu and Kashmir, a recently created union territory (UT) in India's far north where disasters caused by nature and humans have the greatest effect on individuals and make it more vulnerable. The death toll due to various disasters at the national level and Jammu and Kashmir from 2005 to 2018 is shown in Table 1.

Table 1 Natural disaster-related fatalities in India and J & K between 2005 and 2018

Natural disaster-related fatalities			
S. No	Year	Jammu and Kashmir	India
1	2005	1157	22,415
2	2006	345	21,502

In addition to anthropogenic or man-made calamities, J & K is vulnerable to natural disasters. Srinagar and Jammu, both cities, are in seismic zones IV and V. The usual occurrences include avalanches, traffic accidents, and landslides along the highways. Floods have also repeatedly destroyed the economy and affected everyday life of the people. Following is a brief description of a few disasters.

Earthquakes

The westernmost portion of India's Himalayan mountain range is located in Jammu and Kashmir. It has a Medvedev–Sponheuer–Karnik earthquake intensity scale of VIII to IX or higher and is designated as being in seismic zones IV and V. Zone V includes the districts of Kashmir North and Kashmir South. Zone IV includes the districts of Jammu, Kathua, Udhampur, Poonch, Reasi, Ladakh, Leh, and Tribal Territory. Districts in Jammu and Kashmir that make up a large chunk are located in the seismic zone V. Pulwama, Ramban, Shopian, Budgam, Bandipora, Anantnag, Baramulla, Ganderbal, Kulgam, Kupwara, Srinagar and Kishtwar districts are located in the seismic zone V, while the remaining districts are in the seismic zone IV. Since the earthquake database in India is presently lacking, particularly for earthquakes that occurred during the period (before 1800 A.D.), these seismic zones provide a general indication of the earthquakes in each district and should be updated frequently (Fig. 1).

Landslides

In addition to earthquakes, landslides are a widespread and unique geological danger in the area. The size of the mass movement in Jammu and Kashmir ranges landslides to soil movements. Another type of large-scale movement, known as solifluction, is frequent on the snow-topped hills. Flash floods in Jammu and Kashmir are responsible for some of the larger landslides, especially in confined river gorges. These flash floods in the area cause landslides, which ultimately endanger the stability of the hill as a whole. Due to numerous improper development activities, the state's geologically young, unstable, and delicate rocks are now much more vulnerable. Anthropogenic activities such as deforestation, ill-conceived road building and terracing, and encroachment on steep mountain slopes have increased the incidence and severity of landslides. A huge landslide would hit a portion of the state almost every year, causing flooding, fatalities, damage to homes, roads, and other transportation infrastructure, as well as loss of agricultural land (Fig. 2).

Snow Avalanches, Snow Storm, and Snow Fall

Some of the main routes in Jammu and Kashmir like the upper higher ranges in Kashmir Valley are extremely susceptible to avalanches. Avalanches are rarely

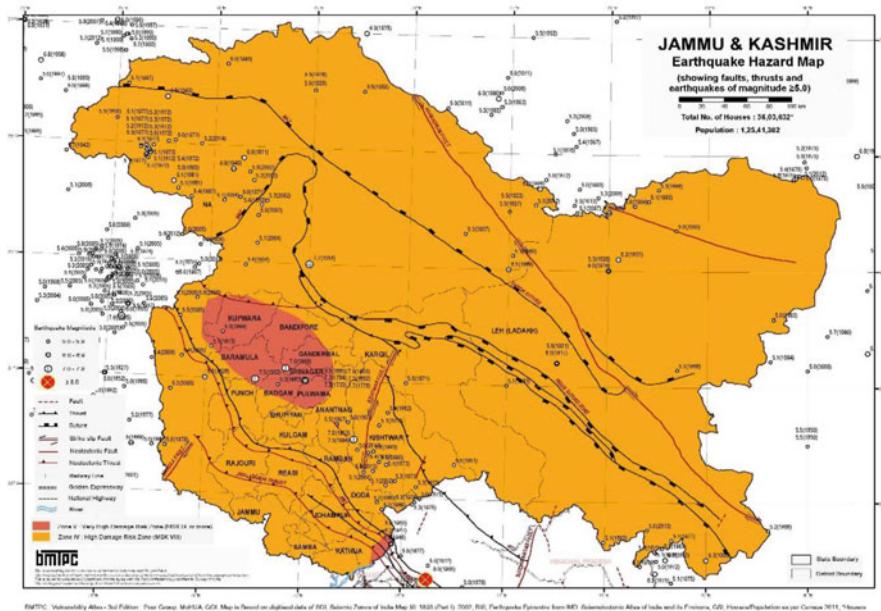

Fig. 1 Earthquake hazard map of Jammu and Kashmir. (Source: *Vulnerability Atlas of India, third edition 2019*)

watched attentively and typically happen within a short time frame of 1 to 2 minutes, making them highly challenging to forecast. The Kashmir Valley has snowfall and rain during the winter due to winds coming from the Mediterranean Sea. The zone's altitude determines the level of coolness. Avalanches have killed several people in the state during the past few years.

Flash Floods

Flash floods are a common hazard in the state because they are short-lived extreme events that typically happen under stationary or slowly moving thunderstorms and last less than 24 hours. This phenomenon has caused a tremendous loss of property and human life in various parts of the region due to the rapid velocity of the stream, which can wipe away all barriers in its path. Floods can also happen throughout the summer when there is a period of continuous rain followed by a sunny day that melts the snow. A district that was dry a few hours before could quickly change into a lake if an embankment is damaged or topped.

Jammu and Kashmir is considerably different from the rest of the nation in terms of its topography, social environment, climate, strategic location, and economics. The region is prone to a variety of hazards, including man-made disasters like road accidents and fires, as well as natural disasters. Table 2 provides statistical data on the number of fatalities brought on by various disaster events in the region.

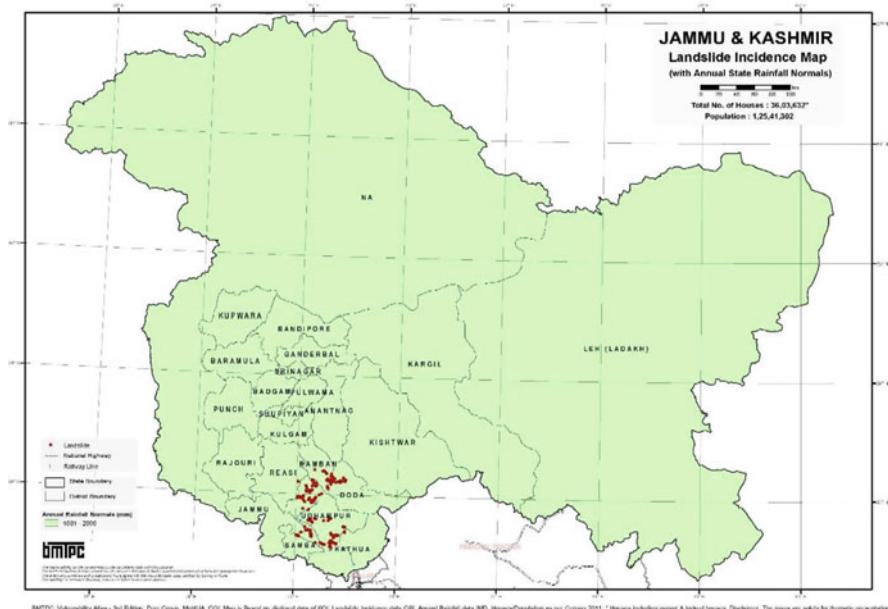

Fig. 2 Landslide incidence map of Jammu and Kashmir. (*Source: Vulnerability Atlas of India, third edition 2019*)

Table 2 Major disasters in the state during 2005–2014

Month/year	Disaster	Impact/loss of life
February 2005	Snow blizzard at Waltengu Nad (Kulgam District)	175 deaths and 128 families affected
October 2005	Earthquake at Baramulla and Poonch	953 deaths and 418 injured
September 2009	Drought 2009 (Kharif)	18 districts affected
August 2010	Cloudburst at Leh	257 deaths and 424 injured
September 2014	Floods in Kashmir and Jammu	257 deaths and 424 injured

Part II

Institutional Mechanism for Disaster Management in Jammu and Kashmir

The state of Jammu and Kashmir was among the first several states in the country to introduce laws for natural disasters. For the improvement of villages, towns, and other areas in the state that were affected by natural calamities, the Jammu and

Kashmir Natural Calamities Destroyed Areas Improvement Act was passed in 1955. The Act's accessibility did not, however, yield many benefits. The government has initiated many programs in the state to reduce the loss of property and human life caused by devastation since the National Disaster Management Act of 2005 was passed. The State Disaster Management Authority (SDMA), the State Executive Committee (SEC), and the District Disaster Management Authorities have already been established by the Government of Jammu and Kashmir in accordance with the provisions laid down in the Disaster Management Act, 2005. Under the supervision of Lt. Governor, the State Disaster Management Authority is functional and working properly. The State Executive Committee, chaired by the Chief Secretary, has also been established. Companies of the State Disaster Response Force (SDRF), which has been established, are getting ready for field work and deployment. By offering capacity-building in terms of tools and instruction, the Fire & Emergency Services (F&ES) and SDRF's present facilities will be strengthened. The Deputy Commissioners have also established the District Disaster Management Authorities. By performing the necessary actions, such as appointing staff, establishing offices, allocating financial resources, etc., all these bodies must be made operational.

In its present state, the State Disaster Management Authority in Jammu and Kashmir is an ongoing, autonomous institution engaged in daily activities related to policy, planning, oversight, implementation, coordination, quality control, and activities related to monitoring, evaluation, documentation, etc. In each district, the District Disaster Management Authority (DDMA), led by the Deputy Commissioner, has been established. The Chief Executive Officer of the DDMA is the Additional Deputy Commissioner of the concerned district. At the district level, the DDMA will serve as the planning, coordinating, and implementing body for disaster management. It will also take all required actions to manage disasters in compliance with the standards established by SDMA. The local authorities, such as urban local bodies, panchayats, development authorities, etc., will see to it that their officers and staff are equipped to handle disasters and conduct relief, rehabilitation, and rebuilding operations in accordance with the regulations.

National Disaster Response Fund (NDRF) and State Disaster Response Fund (SDRF)

A fund established under section 46 of the Disaster Management Act of 2005 is known as the National Disaster Response Fund (NDRF). These guidelines have been created in accordance with section 46(2) of the Disaster Management Act of 2005 (DM Act, 2005) in order to supplement funds from the State Disaster Response Fund (SDRF) and to enable quick assistance in the event of severe disasters. Cyclone, drought, earthquake, fire, flood, tsunami, hailstorm, landslide, avalanche, cloud-burst, and insect attacks are examples of natural disasters that are considered to be of a severe nature by the Government of India and necessitate spending by a state government above the balances in its own State Disaster Response Fund (SDRF). These disasters will qualify for immediate relief assistance from NDRF. The major

fund available to state governments for responses to declared disasters is the State Disaster Response Fund (SDRF), established under Section 48 (1) (a) of the Disaster Management Act, 2005. For general category states/UTs and special category states/ UTs (North East States, Sikkim, Uttarakhand, Himachal Pradesh, Jammu, and Kashmir), the central government contributes 75% and 90%, respectively, of the SDRF allocation. According to the Finance Commission's recommendation, the annual central contribution is distributed in two equal installments. Only expenses related to giving immediate help to the victims may be covered by SDRF. Disasters like cyclone, drought, earthquake, fire, flood, tsunami, hailstorm, landslide, avalanche, cloudburst, pest attack, frost, and cold waves will be covered under SDRF. Subject to the condition that the state government has listed the state-specific natural disasters and notified clear and transparent norms and guidelines for their response, a state government may use up to 10% of the funds available under the SDRF for providing immediate relief to victims of natural disasters that they consider to be "disasters" within the local context in the state and which are not included in the notified list of disasters of the Ministry of Home Affairs (SEC). Based on the recommendation of 12th Finance Commission Calamity Relief Fund and National Calamity Contingency Fund (NCCF) were created. The below-mentioned tables provide all the statistical data of relief as provided by different response funds from time to time in Jammu and Kashmir.

Part III

2014 Floods in Jammu and Kashmir

Heavy rainfall, cloudbursts, inadequate river capacity to discharge water, and insufficient drainage capacity to transport away rainwater to streams are the main causes of floods (Kale, 2004). Natural catastrophes slow down progress. Communities frequently lack the ability to recover from such unanticipated events. Among all of the natural calamities, floods are the most frequent and pervasive. Floods possess great threat to India, making it the world's most affected flood-prone region where about 40 million hectares is plagued by floods (Raghavulu, 2014). Aside from the loss of life, flooding damages homes, properties, the public sector, and industries, causing significant physical and monetary costs. Floods are the most feared of all natural disasters because of their aftereffects, which include the suffering of survivors, the spread of infections, the lack of access to essentials like drinking water and medicine, and the destruction of homes. Numerous factors, like as population growth, fast urbanization, an increase in building in flood plains, and global warming, might be blamed for this (Dang et al., 2011). According to the data available with the Ministry of Home Affairs, the Government of Jammu and Kashmir stated that substantial loss to life and property was caused in many sites throughout the state during the week ending September 3, 2014, and 10 out of 22 districts in the state reported receiving more rainfall than usual. With the exception of Samba and Poonch districts, all the remaining districts (including two

districts of Ladakh) experienced higher-than-average rainfall throughout the ensuing week, from September 4 to September 10, 2014. In the Shopian district, the surplus rainfall was 2,953%, while in the Srinagar district, it was 1,410%. Due to the heavy rains, landslides and embankment breaches inflicted severe damage on numerous districts around the Kashmir Valley, Jammu region, and, in particular, Srinagar district, which was scorched by nature. State played the major role in disaster management to provide logistical and financial support (MoHA). Table 3 shows the damages reported in Jammu and Kashmir during the 2014 floods in the respective districts of both Kashmir and Jammu divisions (Tables 4 and 5).

In addition, 2.54 lakh numbers of houses were damaged and 6.51 lakh hectares of crops was also affected in Jammu and Kashmir. The infrastructure, which includes the telecommunications, power, health, and fuel distribution networks as well as the water supply system, was also severely impacted.

Table 3 Provides the details of allocation and releases of SDRF and NDRF during the years 2010–2011 to 2021–2022

Details of allocation and releases of SDRF and NDRF during the years 2010-11 to 2021-22				
State	Year	Allocation under State Disaster Response Fund (SDRF) (including center and state share)	Release of center share under SDRF	Release from National Disaster Response Fund (NDRF)
Jammu and Kashmir	2010–2011	172.46	77.605	0.00
	2011–2012	181.08	0.00	0.00
	2012–2013	190.13	77.605	0.00
	2013–2014	199.64	423.93	43.53

Affected area	Damage	Extent of damage	
Districts affected	10	Kashmir Division	Budgam, Anantnag, Kulgam, Pulwama, and Srinagar
		Jammu Division	Reasi, Poonch, Jammu, Rajouri, and Udhampur
No. of villages affected	5642	Kashmir Division	2469
		Jammu Division	3173
No. of human lives lost	287	Kashmir Division	91
		Jammu Division	196

Source: 182th report on Rescue, Rehabilitation and Reconstruction in the aftermath of the floods and landslides in Jammu and Kashmir

Relief and Rehabilitation

As per the data provided by the Ministry of Home Affairs, following activities of relief and rehabilitation were performed by the state government with the help of various agencies/departments which includes Indian armed forces, NDRF and SDRF personnel, central forces, Red Cross, Food Corporation of India, public health engineering department, medical department, electricity department, banking employees, etc.

Providing Safe Passage to the Affected Population

The Ministry of Home Affairs also provided information on the rescue and relief efforts made in the state after floods and landslides. In order to conduct search and rescue efforts, the Indian Army, IAF, Navy, NDRF personnel, and central forces were also sent. Over 2.90 lakh people were rescued to safer locations, and 2.92 lakh people were evacuated to safer locations by all authorities. Only the military forces were able to save about 2.14 lakh persons. While CRPF teams saved 27,420 people, NDRF teams saved 50,815 people. The committee was made aware of the Army's deployment of 329 columns, or around 30,000 soldiers, and 224 boats. 53 helicopters and 30 transport aircraft were deployed by Indian Air Force. The Army additionally sent out 17 helicopters. Additionally, the Indian Navy deployed three MARCOS troops. With the essential engineer supplies and equipment, 15 engineers from the Indian Army were dispatched. 955 people from 22 NDRF teams, together with the required tools and equipment, were sent to help the state government with search and rescue efforts. From September 6 to September 25, 2014, the Indian Air Force and Army conducted more than 3000 air missions.

Food and Other Supplies

Food packets Food packets and other critical items were air-dropped as part of the relief operations. To the impacted areas, supplies of food, baby food, water, and medications were sent. Relief camps were set up in various locations. 4226 tents and 1,67,300 blankets were given. 4500.25 tons of stuff, including 1492.4 tons of food and ready-to-eat packets, and 605 tons of water was supplied. IAF dropped 1,31,500 food packs as of September 24, 2014. The Army created 13 camps in Jammu division and six relief camps in Kashmir Valley. 1664 tents were provided by the Indian Red Cross Society. They also sent 1000 kitchen sets and 750 tarpaulins. The state government received 17 dewatering pumps and sent them to Srinagar. There was enough food grain in stock at every depot in J & K. Without receiving payment in advance and on a top priority basis, FCI supplied food grains to the state government in accordance with its needs. The state government of J & K hoisted 997 tons of wheat and 43,873 tons of rice during the month of September 2014 for distribution under PDS/flood relief in Kashmir Division. The impacted families have received free rations for 6 months.

Water Treatment Plants, Drinking Water Supplies, and Medical Assistance

Regarding the availability of drinking water, the state government reported that in the city of Srinagar, almost 80% of water supplies have been restored. In Jammu City, the water supply has been restored to about 90% (i.e., 40 MGD out of 45 MGD). 28 water treatment facilities with a total volume of roughly 6,00000 liters per day have been airlifted and given to the state government. The Army delivered oxygen cylinders and medical help. The Army also provided a mobile oxygen-generating plant. There were 23 different kinds of medications sent, including ORS, IV fluid, paracetamol syrup, antipyretics, antidiarrheal, antibiotics, and antispasmodics. A total of 170 metric tons of medications was delivered. In addition, J & K received 30000 vitamin A bottles, 35 lakh chlorine tablets, 7.5 lakh oral polio vaccine doses, 13.25 lakh measles vaccine doses, 3000 doses of anti-rabies vaccine, 500 vials of anti-snake venom, 25 MT of bleaching powder, and 1 lakh sanitary napkins. There were 51 specialist doctors in total working at Kashmir's hospitals, including 22 physicians, 13 pediatricians, 10 gynecologists, and six anesthetists. Decomposer malathion in the amount of 500 kg was sent to the state from Bathinda by road.

Telecommunication, Electricity Connectivity, and Fuel Stocks

In the state, telecommunications connectivity has largely been recovered. The telecoms, however, are still occasionally erratic. People who were stuck were given free access so they could phone their homes. Most of the state's power supply

has been restored. All government and private hospitals, water supply stations, and aid camps now have power. In Jammu, all 17 damaged 33/11 kV substations have been fixed. Of Kashmir's 36 damaged 33/11 kV substations, 34 have also been repaired. There was enough fuel on hand in Srinagar. However, more motor spirit, high-speed diesel, and LPG were transported into the valley by road. As of October 4, 2014, around 3.2 lakh LPG cylinders have arrived in Srinagar. Of the 45 ROs in Srinagar, 42 were presently in use. The state government told the Ministry that there was no shortage of petrol, diesel, LPG, and kerosene in the valley.

Road Communication, Restoration of Bank Facilities

BRO sent 1462 personnel, 20 bulldozer, 24 excavators, and 18 JCBs to the state in order to restore road communications. Significant roads had been made available for traffic. Of the 745 bank branches in Kashmir Division, 708 were open and operating, and 854 ATMs were also operational out of the total. Whereas all branches and ATMs in Jammu division were operational.

Ex Gratia Amount to the Victims

The announcement of special assistance of Rs. 1000 crore to Jammu and Kashmir by Prime Minister provided much relief to the victims by using the amount in rehabilitation of the flood-affected population in both regions. In addition, ex gratia payments of Rs. 2 lakh to each of the surviving family members of the deceased and Rs. 50,000 to each of the severely injured people were provided from the Prime Minister Relief Fund. The state government has 1105.6 crore in their SDRF available to cover the costs of rescue and relief efforts.

Discussion and Conclusion

Union territory of Jammu and Kashmir is the northernmost region of India and is considered to be one of the most picturesque lands on the planet. But the region has been unfortunately plagued by various natural disasters ranging from earthquakes, destructive floods, snow blizzards, avalanches, landslides, to wind storms, all owing to its peculiar topography, rugged terrain, extreme weather conditions, and unique geographical and geo-climatic settings, which has always caused a huge loss of human lives and property. This chapter attempts to chronologically trace the major disasters of Jammu and Kashmir region and understand the role of government in mitigating the disasters. This chapter critically examined the various policy documents, orders, and by-laws which have been framed and implemented from time to time by the government. The chapter also looked into the role of various government agencies, i.e., National Disaster Response Force and State Disaster Response Force, and other associated government departments.

There are, however, few studies that have examined the immediate aftermath of particular environmental disasters. Studies on the relief and rehabilitation of victims amidst the devastation caused by disasters are scarce. This chapter discussed the natural disaster in Jammu and Kashmir and traced their history of relief and rehabilitation in the region. The legal structure for the rehabilitation of disaster victims appears to be inadequate, and neither an institutional framework nor a policy document is present to support the worst victims of disasters due to the ongoing territorial conflict in Jammu and Kashmir, which periodically causes different battles to be waged between two countries. Government attention is diverted from helping victims of natural disasters to the rehabilitation of armed conflict victims in Jammu and Kashmir owing to territorial conflict. The review of the various legal provisions suggests that the framework for the rehabilitation of disaster victims is insufficient. The government should make a bold and constructive move to establish effective programs in Jammu and Kashmir and to develop a legislatively based policy statement that focuses on the rehabilitation of disaster victims.

Abstract

From the very beginning of the twenty-first century, the world has witnessed many natural disasters. The Sendai Framework for Disaster Risk Reduction 2015–2030 has emphasized on formulating disaster management plans at international, national, regional, and local levels. It also urges the use of traditional,

indigenous, and local knowledge and practices for the disaster risk assessment and preparation of disaster mitigation plans and management disasters. The national disaster management policy of India 2009 describes that the local authorities should ensure the capacity building of their officers and manage disasters and carry out relief, rehabilitation, and reconstruction activities in the affected areas. It also calls for setting up a specific institutional framework for dealing with disasters in megacities. The Odisha government has made provisions to prepare the village-level disaster management plans and national, state, and district-level plans. In this context, we critically appraise the progress of India in empowering the local governments for effective management of disasters at the local level. We argue that it is high time to formally add the responsibility of disaster management by the local governments in the eleventh and twelfth schedules of the constitution. In line with the National Disaster Management Fund and State Disaster Management Funds, local governments should be provided with special Disaster Management Funds. A dedicated department should be created for managing various types of disasters. All disaster-prone villages should have a Village Disaster Management Committee, and panchayats should have a Panchayat Disaster Management Committee.

Introduction

The Sixth Assessment Report (AR6) of the Inter-Governmental Panel on Climate Change (IPCC) forecasts that global warming will reach or exceed 1.5 °C between 2021 and 2040 as compared to the mean temperature of the pre-industrial level (1850–1900). This would cause an inevitable rise in multiple climate hazards and present multiple risks to ecosystems and humans. However, the level of risk will depend on vulnerability, exposure, socioeconomic development, and adaptation. The mid- to long-term risks (2041–2100) assessment points out that risks to natural and human systems would increase manifold compared to the currently observed levels (IPCC, 2022).

India is one of the ten most disaster-prone countries in the world. Both natural and human-induced factors are responsible for making India a disaster-prone nation. 27 of the 36 states and union territories of India are disaster-prone. Almost 58.6 percent of the country's landmass is prone to moderate to very high earthquakes. Over 12 percent of the land is prone to floods and river erosion. Of the 7516 km long

coastline, close to 76 percent is prone to cyclones and tsunamis. Sixty-eight percent of the cultivable area is vulnerable to drought, and hilly areas are at risk from landslides and avalanches (NIDM, 2014).

The High Power Committee on Disaster Management of India has listed 31 types of disasters under five major categories, namely, (1) water and climate-related disasters, (2) geological-related disasters, (3) chemical, industrial, and nuclear-related disasters, (4) accident-related disasters, and (5) biological-related disasters. Of all these five major categories of disasters, we focus only on the natural disasters coming under the broad category of one and two. Under the water and climate-related disasters come (a) floods and drainage management, (b) cyclones, (c) tornadoes and hurricanes, (d) hailstorms, (e) cloud burst, (f) heatwave and coldwave, (g) snow avalanches, (h) droughts, (i) sea erosion, (j) thunder and lightning, and (k) tsunami. Under geological-related disasters come (a) landslides and mudflows, (b) earthquakes, (c) dam failure/dam bursts, and (d) mine disasters.

Based on the observed cyclonic activities from 1891 to 2019, five cyclones developed over the north Indian Ocean region in a year, with an average of four cyclone activities developing over the Bay of Bengal and one cyclone activity developing over the Arabian Sea. However, the east coast has witnessed an increasing number of cyclones in recent years (MoEFCC, 2021). The Bay of Bengal Coast witnesses a substantially higher (five to six times) cyclones frequency than the Arabian Sea coast. Out of the total 618 cyclones formed during 1891–2008, 78% were over the Bay of Bengal coast, and only 22% were over the Arabian Sea. The incidence of cyclonic storms reaching Tamil Nadu and Andhra Pradesh is high during the northeast monsoon season, i.e., October–December, whereas the highest annual number of severe storms occurs on the Odisha–West Bengal coast (NIDM, 2014). India is also witnessing increasing trends in the heatwave over most weather stations except a few stations in the plains along foothills of the Himalayas, southern parts of central India, and east India during the period 1961–2019. There was a decreasing trend in coldwave days at most stations (MoEFCC, 2021). There is also an increasing trend in human fatalities due to lightning and thunderstorms in recent years.

Considering the increasing risk of natural disasters in India, the government needs to strengthen the institutional capacity and redesign to minimize the damages and losses of property and human causalities. The Sendai Framework for Disaster Risk Reduction 2015–2030 states that along with the crucial roles of national and state governments, the active role of the local governments and communities is essential to reduce disaster risk. Against this backdrop, we examine the roles played by the local governments and other local actors in disaster management and suggest a few measures to strengthen the existing institutional architecture. We have done a case study of two cyclone-prone Panchayats of Odisha, India, and examined the roles played by the villages, Panchayats and Panchayat Samitis, and other local actors in the management of cyclones. While appreciating the roles played by the existing local actors, we observe a few gaps and suggest a few proposals for strengthening the local disaster management institutions.

Insights from Literature on the Role of Local Governments in Disaster Management

The Super cyclone of Odisha in 1999, the earthquake of Gujarat in 2001, and the Tsunami of Tamil Nadu in 2004 triggered the urgency to set up a robust disaster management plan in India. This led to the enactment of the Disaster Management Act (DMA) 2005. In order to achieve the goals prescribed in DMA 2005, two things are essential, i.e., (i) incorporating the Urban Local Bodies and Panchayati Raj Institutions (PRIs) in disaster risk planning and management and (ii) enhancing the capacity by giving training to the local authorities. Though there are several provisions in the Disaster Management Act 2005, several gaps exist between the policy and practice. Although the government of India has formulated several well-intentioned policy measures for Disaster Risk Reduction (DRR), they are implemented only at the national level and state levels. These policies are kept only in pen and paper at the local level (Ogra et al., 2021). The Disaster Management Act 2005 is not free from lacunas. Sarkar and Sarma (2006) pointed out that the Act neglected some essential aspects such as disaster classification and declaration of disaster-prone zones. It has not spelled out the responsibilities of the local government clearly and has not prescribed any substantive provisions for them. The DMA 2005 needs amendments to consider that disaster management should be a long-term development-oriented plan.

Tyagi (2010) argued a need for a paradigm shift in disaster management planning in India. Equal importance should be given to all three tiers of government for disaster management. He further stresses that disaster management planning cannot be successful without a poverty alleviation program. A comprehensive strategy is needed where human development, disaster management, and poverty alleviation programs will be incorporated to mitigate the impact of natural disasters. There is evidence that countries with more decentralized government structures experience fewer casualties during natural disasters (Skidmore & Toya, 2013). The decentralization of government structure in the Philippines by integrating urban disaster management bodies and local disaster management bodies has succeeded in reducing disaster loss (Gera, 2018). Political decentralization and fiscal decentralization help reduce the death rates due to disasters. Political decentralization without fiscal decentralization is meaningless, so giving only responsibility to the local government will not serve the purpose. The financial allocation should be made for the local government to accelerate the process of disaster management (Iqbal & Ahmed, 2015).

The initiatives of local communities for assessing disaster risk help in decision-making, sharing information, and enhancing communication between different stakeholders. Hence incorporating local communities at every level of disaster management helps New Orleans combat natural disasters more smoothly (Marie Col, 2007). Community-based disaster management, which includes local administration, organizations, community leaders, civil groups, and public sector officers, proved very helpful in disaster management, mainly in floods in Thailand (Yodsuban & Nuntaboot, 2021). In a study, Vij et al. (2020) found out that the disaster risk

reduction process was more effective when the international NGOs started giving importance to the community-based disaster management approach. In 2017, a new Act was legislated in Nepal. More financial and administrative powers were transferred to the local government to maintain cooperation and coordination among local, provincial, and federal governments for better disaster management. Capili (2003) observed that a community-based disaster management policy should be adopted as the national disaster management policy in the Philippines. Edris and Nibedita (2021) stressed the role of district-level disaster risk management in Bangladesh. It is argued that a district-level disaster management committee is essential for incorporating the local government into the disaster management process more actively. There is a need for a paradigm shift in urban disaster management where the municipal government should play a central role in managing urban disaster risk (Filippi, 2022).

A mixture of traditional knowledge and management skills with traditional disaster governance skills will be more helpful in combating the emergencies. Coordination between top administrations and the local elected officials helps deal with disasters more efficiently. The responsibilities and duties of the local government should be mentioned to avoid any confusion. The local government should be included in every stage of disaster response planning, i.e., pre-disaster, during the disaster, and post-disaster response. Dan and Gordon (2005) found out that New Zealand, Australia, South Africa, and Canada have adopted the multi-level disaster management plan, which empowers the municipal and local government actors. This has helped in making the cost-effective disaster reduction plan in these countries. The civil contingencies Act 2004 strengthened the relationship between different stakeholders. It enhanced the role of local government in disaster management, which provided excellent results to Greater Manchester, the UK, in the field of disaster management (Kathryn & Karl, 2017). Raungratanaamporn et al. (2014) pointed out that the collaboration among different actors such as government, NGOs, communities, and private organizations is very effective for flood management in Thailand. As there is a close relationship between the community and local government, it will be beneficial to implement ground-level policies.

Lack of communication between different agencies and lack of integration among the different levels of government are significant barriers to effective disaster management in Sri Lanka (Abdeen et al., 2021). Crossweller and Tschakert (2021) pointed out that resources are utilized efficiently through shared responsibility among different levels of government. Sharing economy model can also be effective in disaster management in Iran (Seddighi & Baharmand, 2020). Sharing responsibility between different actors of government at different levels helps in disaster management policy in Australia (Atkinson & Curnin, 2020). Rustinskyah (2021) suggested that strengthening social capital, which includes the villagers, people from outside the village, the local government, and private sector, helps in the flood disaster management in eastern Java province.

In California, the role of local government has changed from only being agents of state government to working independently on their own with more critical responsibilities (Waugh, 1994). Provincial governments play crucial roles in distributing

disaster relief in China (Freeman & Thompson, 2009). Local government and municipalities play a significant role in climate governance in South Africa (Du Plessis & Kotzé, 2014). Gerber (2015) pointed out that the local government plays a crucial role in viewing climate change as the most dreadful hazard for the people and suggests various policies for the hazard management process. The emergency program Act of British Columbia, Canada, has a significant feature for placing the local government at the center of emergency management. The local government can announce any emergency if it fulfills the criteria of the emergencies Act. In Japan, under the Disaster Relief Act of 1947, the governor can give the absolute authority of relief activities to the municipalities for the effective distribution of relief. It is found that much of the local resources are allocated for disaster preparedness than recovery, which creates problems in the inefficient working process of the local government (Henstra, 2010).

Additionally, the local government has low revenue-generating power than the higher-level government, limiting the local governments' capacity to manage the disasters independently. Therefore financial allocation should be made for the local government from the central government (Tierney et al., 2001). Gallagher and Hartley (2017) have pointed out that after a natural disaster, the debt level of households reduces as the households use the relief money for repayment of the debt instead of rebuilding their home. This can be checked if the local government will be given more power and responsibility to verify whether people are using the relief money for rebuilding their homes or for any other purpose.

Objective, Methodology, Study Area

In this chapter, we have critically examined the roles played by the Panchayati Raj Institutions and other local actors in disaster management and suggested necessary changes to strengthen the institutional architecture for disaster management.

For this purpose, we have done a case study of the Pipili and Gop Block of Odisha, India, which were severely affected by the Fani very severe cyclone on May 05, 2019. We did a semi-structured interview with the Block Development Officer, Panchayat Development Officer, Panchayat Secretary, Sarpanch, Ward member, Auxiliary Nurse Midwife (ANM), Anganwadi Worker, Accredited Social Health Activist (ASHA), Primary School Teacher, and Gaon Kalyan Samiti President of four panchayats, namely, Rathapurushottampur, Saraswatipur, Jasuapur, and Gop. Figure 1 shows the location of the study area.

India's Institutional Architecture for Managing Disasters

The Disaster Management Act 2005 outlines the responsibilities of the union, state, and local governments [Panchayati Raj Institutions (PRIs) and Urban Local Bodies (ULBs)]. Keeping in view of the federal character of the nation, India has created a decentralized institutional architecture for the effective management of disasters at

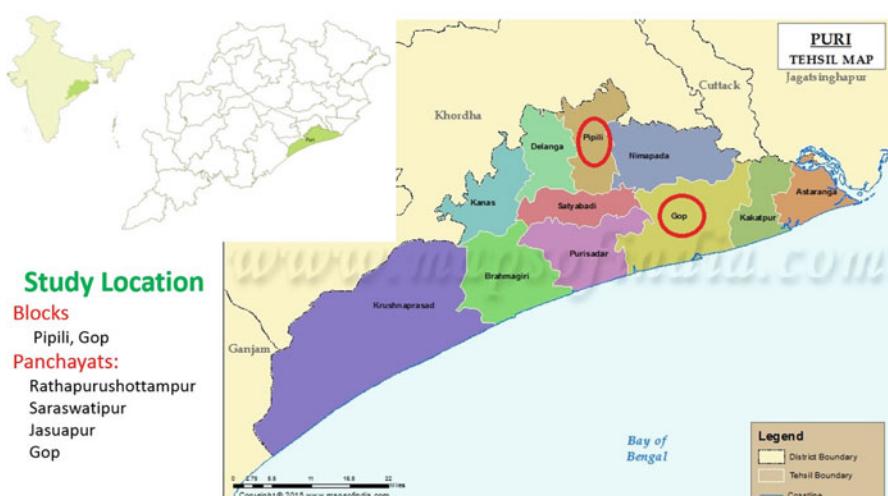

Fig. 1 Study location map

all levels. However, the state governments play bigger role compared to the national government. Although the Union government provides financial support, the respective state governments take the responsibility of evacuation before the disaster, rescue operations during the disaster, and providing relief and payment of compensation after the disaster. Funds for the disaster management, distribution of relief, and payment of compensation are drawn from National Disaster Response Fund (NDRF) and State Disaster Response Fund (SDRF) as per the rule books. Figures 2 and 3 provide the graphic representation of the institutional architecture of the disaster management system at the national and state levels, respectively. Keeping in view the efficient management of the disasters by the state government of Odisha, we have presented the institutional network of the Odisha Disaster Management Authority (OSDMA) in Fig. 3.

Over the years India has strengthened the capacity of early warning system, disaster forecast system, disaster relief centers, workforce for evacuation and rescue operations, and post-disaster operation and management practices. Due to the continuous efforts of the government, the public awareness regarding the standard operating procedures during the disaster has improved significantly. The multi-pronged approach of both national and state governments, the human casualties due to disasters have declined substantially.

International Collaboration and Leadership

The Union government has been taking up initiatives to exchange ideas between countries regarding disaster management and mitigation practices. Similarly, for strengthening the disaster forecasting system and early warning system and

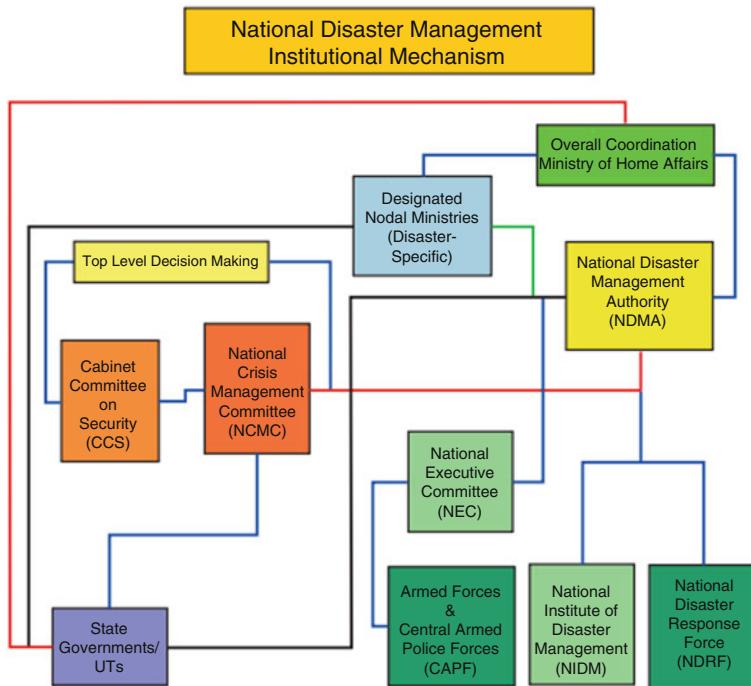

Fig. 2 National-level disaster management – basic institutional framework. (Source: NDMA (2019))

exchange of data, governments have partnered with both the national and international research institutes and other leading agencies. India has also taken the leadership to form the Coalition for Disaster Resilient Infrastructure (CDRI) in September 2019.

Legal Provisions for the Role of Local Governments

Disaster Management Act of the Government of India

CHAPTER VI of the Disaster Management Act (DMA) 2005 describes the role of the local authorities in disaster management: The DMA has made provision for the following functions to be rendered by the local authorities: “(1) Subject to the directions of the District Authority, a local authority shall (a) ensure that its officers and employees are trained for disaster management; (b) ensure that resources relating to disaster management are so maintained as to be readily available for use in the event of any threatening disaster situation or disaster; (c) ensure all construction projects under it or within its jurisdiction conform to the standards and specifications laid down for prevention of disasters and mitigation by the

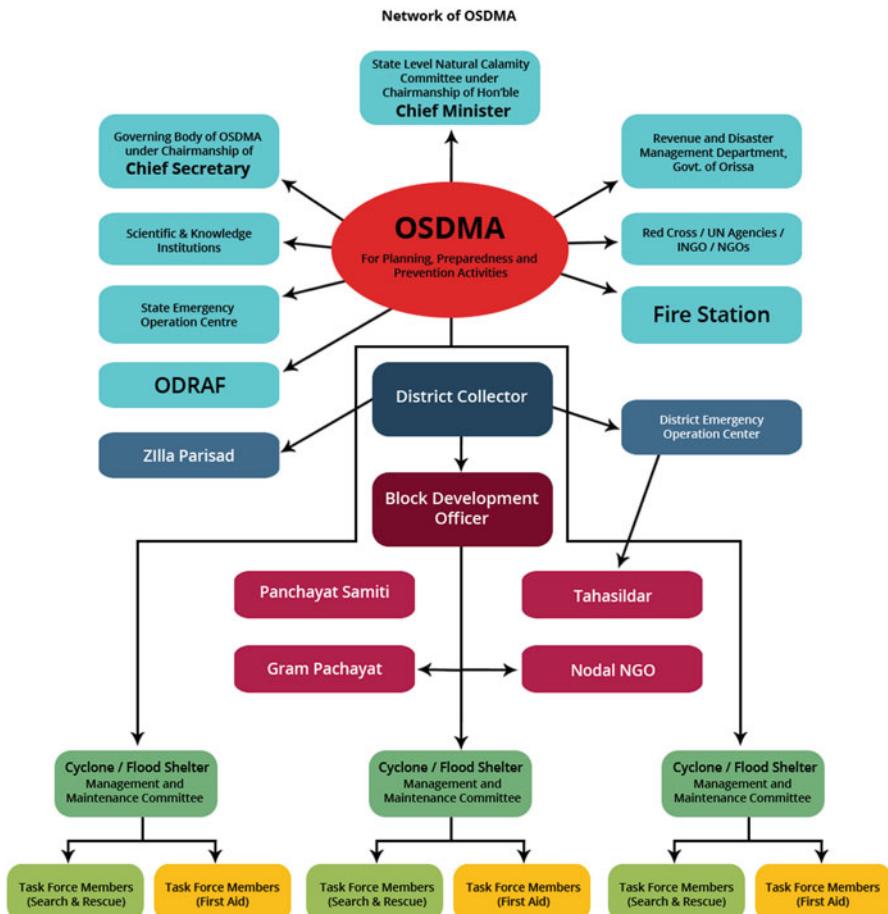

Fig. 3 Institutional framework for disaster management in Odisha

National Authority, State Authority, and the District Authority; (d) carry out relief, rehabilitation, and reconstruction activities in the affected area following the State Plan and the District Plan.” The DMA also empowers the local authority to take other measures necessary for disaster management.

State Disaster Management Policy

Odisha’s disaster management policy makes provision to decentralize the management of disasters to the Block and Gram Panchayat/municipality levels and strengthen their institutional and functional capacities. For this purpose, the policy prescribes the involvement of the Panchayati Raj Institutions and Urban Local Bodies in the pre-disaster phase, the response phase, and the recovery and

rehabilitation phase of a natural disaster. Due to the physical proximity to the people, local governments enjoy the comparative advantage of assessing the vulnerability of the households, intensity of the disaster, and prompt reach out to the worst affected people. Therefore the state disaster management policy gives emphasis to empower the local governments (GoO, 2005).

The government of Odisha brought an ordinance on December 24, 2021, to amend the Odisha Grama Panchayats Act (OGPA) 1964 and The Odisha Panchayat Samiti Act (OPSA) 1959. The state government has expanded the powers of the Panchayats provided under clause 44 (h), which requires the Panchayats to take measures to control the spread of epidemics and other infectious diseases. The amendment empowers the Panchayats to prepare the disaster management plan at the village and Gram Panchayat level, integrate the same with the Panchayat development plan, build the capacity of all stakeholders, facilitate and carry out the relief, rehabilitation, and reconstruction activities, in disaster-affected districts in accordance with the state and district plan. The amendment also allows the Panchayats to undertake other measures as may be necessary for disaster management. The amendment to OPSA 1959 has expanded the Panchayat Samiti's powers to make development plans and added disaster management and all other powers vested to the Panchayats.

Case Study of Odisha

Disaster Profile of Odisha

Odisha ranks in fourth place in the composite Hazard Index of Indian states that includes the indicators namely, earthquake, landslide, flood, drought, cyclone, tsunami, avalanche, heatwave, coldwave, coastal erosion, lightning, forest fire, fire, and industrial hazard (NIDM, 2018). Table 1 presents the incidence of cyclones in Odisha between 1737 and 2021. In recent years the maximum number of cyclones has made landfall in Odisha. Odisha also maintains a unique record of managing the cyclones most effectively by minimizing the number of human casualties. From time to time, the United Nations has lauded the disaster management strategy, especially the ambitious mission of zero casualties and massive evacuation operations.

Along with the high risk of cyclones, Odisha is also highly vulnerable to floods, heatwaves, drought, and lightning.

Flood: The 482-km-long coastline of Odisha exposes the state to floods, cyclones, and storm surge. The floods are usually caused due to heavy rainfall in monsoon seasons and the flow of water from neighboring states of Jharkhand and Chhattisgarh. The flat coastal belts with poor drainage, high degree of siltation of the rivers, soil erosion, breaching of the embankments, and spilling of floodwaters over them cause severe floods in the river basin and delta areas.

Heatwave: Odisha faced an unprecedented heatwave situation in 1998; the state recorded the death of 2042 persons. In the subsequent years, due to massive awareness campaigns, the number of casualties has fallen drastically.

Table 1 Incidence of cyclones in Odisha between 1737 and 2021

Sl. no	Date/year	Category of cyclone	Landfall place
1.	7–12 October 1737	Super cyclone	Crossed West Bengal Coast over Sundarbans and had an impact over Odisha
2.	31 October 1831	Very severe cyclonic storm	Crossed Odisha Coast near Balasore. Loss of life 50,000
3.	2–5 October 1864	Very severe cyclonic storm	Crossed West Bengal Coast near Contai and had an impact on Odisha
4.	1–2 November 1864	Very severe cyclonic storm	Crossed Andhra Pradesh near Machilipatnam and had an impact on Odisha
5.	22 September 1885	Super cyclone	Crossed Odisha Coast at False Point, Loss of life – 5000
6.	14–16 October 1942	Very severe cyclonic storm	Crossed West Bengal Coast near Contai and had an impact on Odisha
7.	8–11 October 1967	Very severe cyclonic storm	Crossed Odisha Coast between Puri and Paradeep
8.	26–30 October 1971	Very severe cyclonic storm	Crossed Odisha Coast near Paradeep. Loss of life 10,000
9.	14–20 November 1977	Super cyclone	Crossed Andhra Coast near Nizampatnam and had an impact on Odisha
10.	4–11 May 1990	Super cyclone	Crossed Andhra Pradesh Coast about 40 Km S-W of Machlipatnam and had an impact over Odisha
11.	25–31 October 1999	Super cyclone	Crossed Odisha Coast near Paradeep at noon of October 29
12.	12–14 October 2013	Very severe cyclonic storm “Phailin”	Crossed Odisha Coast near Gopalpur on the evening of October 12
13.	12–14 October 2014	Very severe cyclonic storm “Hudhud”	Crossed Andhra Pradesh Coast at Vishakapatnam and impact on south Odisha
14.	10–12 October 2018	Very severe cyclonic storm “Titli”	Crossed Andhra Pradesh Coast at Palasa and severely affected south Odisha
15.	03 May 2019	Extremely severe cyclone “FANI”	Crossed Odisha Coast near Puri
16.	8–10 November 2019	Very severe cyclonic storm “Bulbul”	It affected the coastal districts of Odisha
17.	20 May 2020	Super cyclonic storm “Aman”	Crossed West Bengal Coasts. It affected the coastal districts of Odisha
18.	23–26 May 2021	Severe cyclonic storm “Yass”	Crossed between Paradip (Odisha) and Sagar islands (West Bengal)
19.	3–5 December 2021	Cyclonic storm “Jawad”	Landfall near Puri district (Odisha)

Source: SRC ([n.d.-a](#))

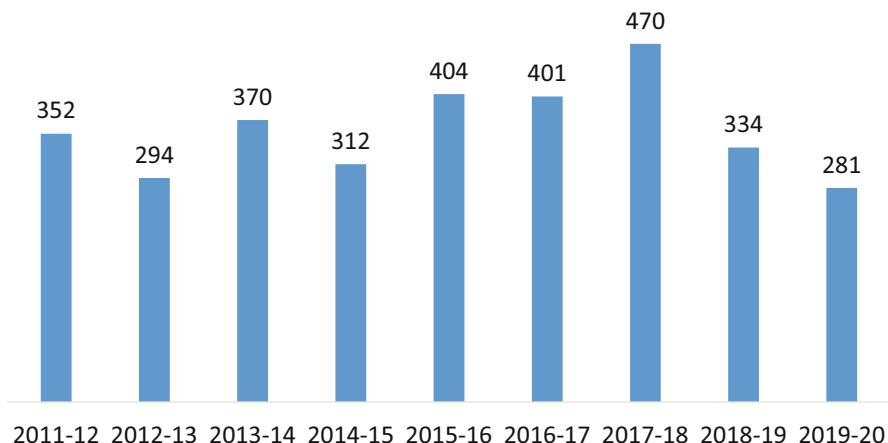

Fig. 4 Total number of deaths due to lightning in Odisha during 2011–2020. (Source: SRC ([n.d.-b](#)))

Drought: About 70 percent of the total cultivated areas in the state are prone to drought. Though Odisha receives an average annual rainfall of 1500 mm, there are wide variations from year to year. The state records at least one severe drought in every decade. Odisha has faced drought for most of the years since the latter half of the 1990s. 47 out of 314 blocks are found to be chronic drought-prone zone.

Lightening: In recent years, the number of deaths due to lightning is showing a rising trend. Figure 4 shows the number of deaths reported during 2011–2012 and 2019–2020. The state government is taking several measures to create awareness regarding the risks of lightning and thunderstorms and the protocols to be followed in these situations.

Disaster Management in Odisha

In case of inputs received from the meteorological department and any other sources regarding the possibility of a disaster such as a cyclone, the Chief Minister conducts a review meeting of the top officials. The entire state machinery is alerted to remain prepared for all eventualities. Top officials of each department review the situation of each department under the leadership of the Chief Secretary and the Special Relief Commissioner. The district collectors of the potentially affected districts are alerted to prepare people's evacuation to safe places and keep the relief materials ready. National Disaster Response Forces from the center and Odisha State Disaster Response Forces (ODRAF) are sent to the most vulnerable places to remain prepared for rescue operations. In case of the severity of the disaster, top officials from the state level are deputed to the possibly most affected districts. Based on the instructions of the district collector, all Block level officials are alerted to mobilize all workforce and other resources at the village and Panchayat level. The Block

Development Officer serves as the nodal officer to coordinate among the line departments, elected representatives – Sarpanch, ward members – volunteers (called Aapda Mitras), non-governmental organizations (NGOs), self-help groups, auxiliary midwife nurse (ANM), Accredited Social Health Activists (ASHA) workers, and Anganwadi workers. The BDO assigns the responsibilities to each person, monitors the local level, and updates the situation to the higher authorities.

Table 2 summarizes responsibilities taken up by all actors at the local level before the disaster, during the disaster, and after the disaster.

Gaps and Suggestions

The 73rd and 74th constitutional amendments seek to transform the PRIs and ULBs into self-governments. Due to increasing frequency of disasters, the Panchayats should play an active role in disaster management and mitigation. The Disaster Management Act 2005 provides only agency functions for the disaster management. This needs to change immediately. Panchayats should be provided with the statutory power to manage the disasters. Therefore, the 11th and 12th schedules of the constitutions should be amended to add the disaster management powers. Similarly, Chapter VI of DMA, 2005 should be amended to insert the explicit role of local governments in disaster management. During the COVID-19 pandemic, grassroots institutions played a crucial role in managing the health and migrant workers' crises. The state government of Odisha has recently amended the legislation to transfer the responsibility of disaster management to the Panchayat Samitis and Panchayats. However, Panchayats lack the financial powers for this purpose. Similarly, Panchayats do not have a disaster management plan. All villages do not have a disaster management plan. Keeping in view the increasing frequency of the disasters, PRIs and ULBs should be strengthened to manage the disasters effectively. We provide the following suggestions to strengthen the disaster management system at the local level.

Separate Department for Disaster Management

The revenue and disaster management are looked after in a single department. Due to the rise in the frequency of disasters, the department's workload has gone up substantially. Disasters are no more confined to specific seasons. During both summer and monsoon seasons, cyclones and floods occur in different parts of the state. Lightning and thunderstorms are also occurring during the summer and monsoon seasons. In recent years the number of deaths due to lightning has been increasing. There is a need to create awareness on the safety protocols to be followed during lightning and thunderstorms. The heatwave in summer and coldwaves in winter also need special preparedness by the administration. Early warning and the creation of awareness about all kinds of disaster requires a dedicated workforce. Continuous update of disaster management plans at the village, Panchayat, block,

Table 2 Role of various stakeholders at village, Panchayat, and Panchayat Samiti level in the disaster management

Source: Authors' compilation based on field survey

and district levels is required to identify the vulnerable locations and households. Regular training and capacity building of the workforce, starting from village level volunteers to the top-level State administrates, is essential for effective disaster management. In the aftermath of the disasters, estimation of damage and losses and payment of compensation remains a sensitive issue. This needs to be dealt by a special department. The existing fire brigades and state-level disaster mitigation forces can be brought under one department and supplemented with more workforce to strengthen the disaster management and mitigation department. To ensure better coordination, district collectors at district level and Block Development Officer/Tehsildar at block/taluk levels can be kept as nodal officers.

Village and Panchayat Disaster Management Committee

All disaster-prone Panchayats should form the Village Disaster Management Committee (VDMC) in each village under the leadership of ward members. The VDMC should include the Ward member, at least five volunteers from the village, and five members from self-help-group (SHG), ASHA, and Anganwadi workers. Similarly, at the Panchayat level, a Panchayat Disaster management Committee (PDMC) should be formed under the leadership of the Sarpanch. The PDMC should include the Sarpanch, Panchayat Executive Officer, Gram Sathi of all villages, ward members, one SHG member from each village, ASHA, and Anganwadi worker from each village.

Panchayat Disaster Response Fund

In line with the National Disaster Response Fund and State Disaster Response Fund, a separate fund should be created at the Panchayat level (Panchayat Disaster Response Fund) and Panchayat Samiti level (Panchayat Samiti Disaster Response Fund) for the prompt response to the disaster. Every Panchayat may be provided with ten lakh rupees and Panchayat Samiti with fifty lakh rupees.

Panchayat Disaster Management Plan

All disaster-prone Panchayats should prepare a disaster management plan and update the same regularly.

Conclusion

The IPCC assessment report six has warned that global warming will exceed 1.5 degrees Celsius much before 2050. This would increase the incidence of natural disasters in several forms. The Sendai Framework on Disaster Risk Reduction

appeals to the member nations to strengthen their institutional capacities, including national-level government to local level government, community members, market, and non-government organizations. The Disaster Management Act of India and similar legislation at state levels provide the active involvement of PRIs and ULBs in disaster management. The Government of Odisha has recently amended the Panchayati Raj Act to transfer the disaster management responsibility to the Panchayat Samitis and Panchayats. Based on the case study in two cyclone-affected blocks of Odisha, India, we have suggested three crucial suggestions to strengthen the PRIs for the effective management of the disaster: (1) a dedicated disaster management department should be created; (2) in line with the National and State Disaster Response Funds, a disaster response fund should be created at the Panchayat Samiti and Panchayat level; (3) disaster-prone villages should form a Village Disaster Management Committee and at Panchayat level a Panchayat Disaster Management Committee; (4) all disaster-prone Panchayats should prepare and regularly update the disaster management plan; (5) in Chapter VI of the Disaster Management Act, 2005, independent roles of PRIs and ULBs during the disaster management should be added; (6) the 11th and 12th Schedules of the Constitution should be amended to add the disaster management power. All states should take prompt measures to transfer all functions, functionaries, and funds to the PRIs and ULBs for transforming them into local self-government. The empowerment of PRIs and ULBs would help to mitigate the disasters effectively.

Abstract

Local police along with civil defense and home guard form critical local capacity against disaster risk and emergencies as first responders. These forces have an advantage over other forces such as NDRF, paramilitary, and even armed forces due to their proximity to the affected areas which considerably reduces the response time and familiarity with the local conditions vulnerability, risk, capacities, and sociocultural realities. Regular, comprehensive, and quality DRR capacity development programs for local police and auxiliary forces are essential; hence, the chapter would examine the existing DRR induction, orientation, and training programs for police by institutions such as NDMA, SDMAs, NIDM, NDRF, etc. It attempts to analyze different technical aspects and components of training – communication systems, information dissemination, risk communication, community engagement, search and rescue, response, and relief. The current

paper also studies the adequacy of these training programs and analyzes gaps therein through review and comparative analysis of the global best practices of DRR training to the police. The chapter would also evaluate the current level of effectiveness of local police during disasters through a case study approach.

Apart from technical expertise, qualities and skills like empathy, sensitivity, and compassion are indispensable for the police and other local forces to deal with trauma stricken people in disasters and emergencies especially the most vulnerable groups like children, people with disability, women, minorities, senior citizens, etc. Hence, the chapter also examines the existing training modules for their adequacy to inculcate emotional intelligence in the police.

Keywords

DRR · Police · Civil defense · Home guard · Training · Capacity building · First responders

Introduction

Disaster risk reduction is a very important aspect of the police administration. It may be law and order and response to natural calamities or disaster, but also the police has greater role in disaster preparedness phase before the disasters. The roles and responsibilities of police come to the forefront when there is a disaster which requires immediate attention and action of police in the event. Police played a crucial role in massive evacuation carried out before cyclone Vayu of 2019 and in Cyclone Fani. The role of police is not limited to the phase of disaster response alone. The voluntary work of police is needed for successful management of post-disaster scenario. The police can perform role in pre-, during, and post-disaster management phase (GIDM, 2020).

No matter what type of disaster it is, the police team can be the first responders at the incident site and establish bondage with the affected local community. The police force is much familiar to the area under their jurisdiction so they can effectively perform their role in disaster risk management and development of strategies.

Sendai framework Target E talks about development of local level disaster risk reduction strategies which are in line with state level and district level. The police force can play an effective role in development of such local level strategies for disaster risk reduction. However the police force is mostly used during response phase only. Necessary training programs to police force would stimulate the involvement of police force in the entire process of disaster risk management (GIDM, 2020).

Objectives

The aim of this research paper is to analyze the adequacy and effectiveness of training programs provided to the police. The objectives of the research paper are as follows:

- Adequacy of these training programs and analyze gaps therein through review and comparative analysis of the global best practices of DRR training to the police.
 - Evaluate the current level of effectiveness of local police during disasters through a case study approach.
 - Examine the existing training modules for their adequacy to inculcate emotional intelligence in the police.
-

Importance of Involvement of Police in Disaster Risk Management

On the occasion of any emergency or an event of disaster, the district and state level authorities cannot wait for the response of specialized force like National Disaster Response Force/Armed Forces. Many times, it is not advisable or feasible to obtain specialized force. Police force is the first and best responders to help and manage in disaster and emergency situation because of their proximity to the incident site, awareness about local terrain, wider reach and better knowledge of locality and culture, and established communication system (Julian Laufs, 2020).

On the occasion of an event of disaster, sometimes the state and district level authorities cannot afford to wait for response of specialized forces, like NDRF/ Armed forces. Moreover, on many occasions, it might not be advisable or feasible to obtain/deploy specialized armed forces and NDRF. At the same time, due to police's proximity to the incident sites, familiarity with the local terrain, wider reach and better knowledge of background of the locality and culture, and established communication system, they are one of the first and best responders to help manage any crisis situation (Julian Laufs, 2020).

Training Need Analysis

Police officers and other staff members are frequently getting involved in managing disasters and emergencies. The police officers adopt different styles of policing based on the responses and reactions of citizens during emergencies. The style of policing may vary based on the scale, nature, and stage of the disasters. Therefore, it is crucial for the police force to understand the behavior of citizens in order to ensure the compliance of the citizens (Bonkiewicz & Ruback, 2012).

In order to increase the effectiveness of police in disaster risk management, the police force and department should modify their style of policing and strategies for various types of disasters and emergencies to accommodate the behaviors, expectations, and priorities of disaster affected people. Therefore, police officers require training to be cognizant in people expectations and realizing social impact of disasters and emergencies (Bonkiewicz & Ruback, 2012).

It is not clear that up to what extent the police force may be able to modify their style of policing during the disasters and emergencies. Particularly in developing

countries, police force is under-resourced and insufficiently trained. Police responses to disasters and emergencies have focused on the importance of sensitizing police officers towards disaster affected people and towards their own roles and responsibilities during crises (Chirambwi, 2016).

During the disasters and emergencies, the police officers are at high risk of developing psychological problems, such as symptoms of substance abuse (Boscarino, 2015), trauma (Kowalski, 2019), acute stress disorder (Regehr et al., 2019), psychological distress (Kerswell et al., 2019), posttraumatic stress disorder (PTSD) (Haugen et al., 2012), fear, as well as anxiety and depression (Mao et al., 2018).

The police forces, often involved in response to disasters and emergencies, were given new responsibilities such as crowd management, maintaining public order, retrieval and removal of dead bodies and transport, and aid for disaster affected people. While fulfilling the responsibilities, the police may face situations where some people may be hostile towards police officers (McCanlies et al., 2014). The police also need a training on communication with community in disasters and emergency.

The research studies have mentioned the importance of training as an effective way of mitigating and managing of disasters. The training facilitates social support networks for police force (Bakker et al., 2016) and focusing on strengthening and enhancing resilience among police officers. This is further induced to reduce the risk of depression and substance abuse of disaster affected community (van der Velden et al., 2012). The higher level of police officers who are supervising the police on ground should be trained to better lead their frontline officers during disasters and emergencies (Kowalski, 2019).

The decision making and performance and retaining of existing police force can be enhanced by providing adequate training and well-established practices. Training and education can reduce new threat perceived by the police officers (Flavin, 1998). The knowledge of the risk can be a major tool for the police officers to create awareness among the community and also to protect themselves and their relatives (Gellert et al., 1996).

Role of National Institute of Disaster Management in Training of Police

National Institute of Disaster Management (NIDM) Ministry of Home Affairs, Government of India, is a premier institute and a Statutory Body (under Disaster Management Act 2005) for training, research, documentation, awareness, and human resources and capacity development in the field of disaster mitigation and management in India and in the region.

The National Institute of Disaster Management has conducted 323 training programs during 2015–2016 to 2019–2020. About 13,265 participants have attended the trainings in the past 5 years. About 5–13 percent of police only attested the disaster management training programs conducted by NIDM during the past 5 years.

Table 1 Year wise % police participation in DM training organized by NIDM

Year	No. of programs conducted	% of police participated
2015–2016	52	12
2016–2017	43	13
2017–2018	46	11
2018–2019	52	8
2019–2020	130	5
Total	323	8

Source: Trainee data base, National Institute of Disaster Management

The percentage of participation of police is much less. During 2015–2016 to 2017–2018, above 10 percent of police has participated, and during 2018–2019 to 2019–2020, less than 10 percent of police only attended the disaster management training programs. The data makes it evident that the police participation in disaster management training is not up to the mark. There is a need of organizing more programs for police personnel (Table 1).

Role of Police Academy in Training of Police

Police Academy is a certified institution that is dedicated to provide world-class police training and encouraging the highest standards of performance, adopting the latest training technologies, employing best practices in policing, and enhancing the quality of training to achieve excellence in both substance and methods of delivery. Each state government has its own Police Training Academy in different names. It plays crucial role in providing training to police force (Table 2).

Among 36 states and union territories, only 14 States and UT Police Training Academy only conducted disaster risk management training programs during 2015–2016 to 2020–2021. During this period, about 41 disaster risk management training programs were conducted by State/UT Police Training Academy and only 1518 police personnel participated in the training programs. Assam has incorporated relief and disaster management subject for newly recruited police personnel.

Tamil Nadu has given priority in organizing disaster management trainings. During 2015–2016, Tamil Nadu is the only state which conducted disaster management training for police force. During 2015–2016 to 2017–2018, Tamil Nadu has organized three training programs and covered large (1057) number of polices. Tamil Nadu is top in conducting disaster management training programs to police; but during 2018–2019 to 2020–2021, no program was conducted.

During 2017–2018, about five states/Police Training Academy, i.e., Tamil Nadu, Meghalaya, Himachal Pradesh, Karnataka, and Odisha, have conducted the disaster management trainings. During 2019–2020, about seven states/UT Police Training Academy have conducted disaster management training, viz., Andaman and Nicobar, Daman and Diu, Goa, Mizoram, Sikkim, Rajasthan, and Telangana. During 2020–2021, only four states/UT Police Training Academy have conducted disaster

Table 2 Year wise no. of disaster management trainings conducted by State Police Training Academy and number of police participated

management training, namely, Jammu and Kashmir, Rajasthan, Telangana, and Punjab. Table is reveal that the Police Training Academy is not shown much interest on organizing disaster risk management training programs for police personnel.

Role of Administrative Training Institutes (ATIs) in Training Police in DRR

The State Governments in India were required to set up state level training institutions as per the recommendations of the Administrative Reforms Commission (ARC). In connection with this, the Administrative Training Institutes were promoted in all the states with different names and different objectives. The mission is to “promote good governance by transforming the functionaries involved in the process of Governance through enhancing their competence and administrative capability by providing quality training in a transparent framework.”

It is revealed that among 36 states and union territories, only three administrative institutes conducted disaster risk management training programs during 2015–2016 to 2020–2021. With reference to training database available from the respective ATI website, it is observed that except following ATIs other ATIs have not conducted DRR training programs for the police. During 2015–2016 Chhattisgarh Academy of Administration, Raipur has conducted disaster management training program for police, but the data about number of participants and content of the program is not available. During 2016–2017 State Institute of Public Administration and Rural Development (SIPARD), Agartala has conducted a training program on role of police in disaster management, and about 25 police officers attended the training program. The duration of the program was 3 days only. During 2018–2019, Andhra Pradesh Human Resource Development Institute (APHRDI) has conducted training program on disaster management for 30 police officers. It is also observed that no ATIs are having DRR training module for police.

Case Study

District Disaster Management Authority (DDMA) Ri Bhoi District of Meghalaya organized training program for police officials on the role of police personnel on emergency management, search, and rescue/first aid in disaster during 2019–2020 November 2018. The training program has covered Understanding Disaster Management, Group Exercise on the Impacts of Disasters and Presentation, the Role of Police in Emergency Management, Fire Safety, and Search and Rescue/First Aid in Disaster. About 31 police officers participated in this training program.

The first session of the training has covered basic concept and definition of disaster, hazards, and disaster management cycle including response, rehabilitation, and reconstruction. It also covered prevention, mitigation, and preparedness in pre-disaster activities. The second session was on disaster impact. In this session,

the participants were divided into four groups, and they have discussed on social, economic, psychological, and physical impact of disaster.

Participants also learned the role of police in emergency management. In this session, they have discussed the role of police in search and rescue, deployment of manpower, prevention of crime, security during distribution of relief materials, and relief management, management of relief camps, transportation, coordination for casualty information, disposal of dead bodies, family liaison officers, media management, and crowd management.

On the second day, the first session was about fire safety, in which they have discussed about types of fire, safety measures for fire and safety tips for survival, gas fire, health hazards, explosion hazards, first aid golden rules of first aid, and rescue method during fire rescue. The last session was about search and rescue and first aid in disaster. This session has covered using ropes and knots for rescue operation, emergency bandaging, different methods of rescue and transport of victims, various first aid techniques, and step by step of conducting mock drill.

This is to appreciate that District Disaster Management Authority (DDMA), Ri Bhoi District of Meghalaya, has organized a special training program exclusively for the police. The course was well designed. Two days training is merely not enough for the police to learn about disasters and their roles. The number of days to be increased. We can consider that this is a basic training to police, but of course the duration of the course should be increased. There is no evidence of providing training materials to participants. The training material helps participants to read and understand and recollect the information learned from training, so training material should be provided to participants for ensuring the quality of training.

The Module of National Disaster Management Authority

The Training Regime for Disaster Response, Volume – I (2008), prepared by the National Disaster Management Authority has proposed training of trainer course in disaster response for faculty members of training institutions of state governments/ central police forces (CPFs). The training was proposed for disaster response training in the training institutions of state governments as also of the central police forces. The suggested course module is for 6 weeks with the objective of understanding, from a trainer's perspective, the concepts and definitions of search, rope rescue, water and flood rescue, and also management of different types of disasters and emergency including nuclear, biological, and chemical emergencies and medical emergencies and teaching the same to the trainees, including effectively handling their questions and doubts during the training.

The training module includes Collapsed Structure Search and Rescue, Rope Rescue, Water and Flood Rescue, Essentials of Fire Fighting and Control, Medical First Response, Radiological Emergencies, Biological Emergencies, Chemical Emergencies, Communication during Disasters, Dignified Management of Dead Bodies, Case Studies of Major Disaster Events, Disaster Management Act 2005, National Disaster Management Authority (NDMA), and National Disaster Response

Force (NDRF). The module has covered 179 theoretical sessions, 74 demo sessions, and 78 practical sessions. Mental health aspects also need to be included in the module.

It is observed that the above suggested module is well designed and it should be implemented. The faculty members of the training institutes should impart this training to the police force for enhancing the performance of police in disaster risk reduction.

Conclusion

It is evident from the present study that the role of police in disaster and emergency is crucial and they play a vital role, but they have not received the adequate training programs on disaster risk management. The National Institute of Disaster Management is a nodal agency in organizing disaster management training programs for government officials, but enough trainings were not organized for police officers. State Police Training Academy is a nodal agency for conducting training program for police officers, but majority of the State Police Training Academy has not organized disaster management-related training programs for police officers. There is a major gap in organizing training programs for police in disasters and emergencies.

Recommendations

- Being a nodal agency to organize disaster risk management training programs, the National Institute of Disaster Management should organize special training programs for police in disasters and emergencies.
- The women police also plays a crucial role in disaster management protecting safe guarding women and children in disaster and emergency. Therefore, the Mahila Police should be given adequate training programs on disasters.
- The State Police Training Academy/schools play a major role in training police officers; therefore, the State Police Training Academy should focus on conducting training programs on disaster management for police.
- Subhash Chandra Bose Aapda Prabandhan Puraskar may be awarded to motivate the Police Training Academy and Administrative Training Institutes which conduct more number of training program on disaster management.
- Administrative Training Institutes play crucial role in enhancing the competence and administrative capability by providing quality training in a transparent framework to the functionaries, but inadequate training program on DRR for police has been observed. The ATIs should focus on conducting more training program on DRR for police.
- National Institute of Disaster Management, Police Training Academy, and Administrative Training Institutes should focus on developing training modules

on DRR for police to build the capacity and enhance the performance police in DRR.

Abstract

Kerala, the southwest coastal state of India which ranks high on the Human Development Index, became vulnerable to severe flooding during the southwest monsoons of 2018. The state faced the worst floods in the century due to above-normal rainfall from June to August 2018. The above-normal rainfall was supplemented by a lack of integration of sustainable development practices and

disaster risk management strategies. The floods affected all the districts of the state and led to the loss of over 400 precious lives along with extensive damage to infrastructure and property. It also triggered about 341 landslides in the area. The community including fishermen and women-centric organizations like Kudumbashree participated actively in responding to the disaster. Technology including WhatsApp, GIS, and crowdsourcing was used actively by the community during the search, rescue, and relief phase. The floods highlighted many constraints like lack of proper management and monitoring of critical natural resources such as water and land which left the state unprepared for major disasters caused by natural hazards. The disaster also highlighted crucial lessons to be adopted by other coastal states of the country which are expected to face increased flooding in the coming times due to climatic changes.

Introduction

Kerala, the southernmost state of India, is generally referred to as “Gods own country” due to its beauty and rich ecosystem. There are two rainfall seasons in Kerala. A southwest monsoon or Edavapathi arrives in late May or early June, and a northeast monsoon or Thulam arrives in mid-October. Every year, the monsoon rains constitute an essential component of the state’s season. However, the southwest monsoon of 2018 brought devastating floods with it. The floods experienced by the state were some of the worst ever recorded. More than 400 individuals died as a result of the disaster. The Idukki dam’s five overflow gates were all opened at the same moment, while the Malampuzha dam’s five gates in Palakkad were opened for the first time in 26 years (Government of Kerala, 2018). In the districts of Wayanad and Idukki, torrential rainfall resulted in major landslides. As a result, the hilly districts became isolated.

Kerala floods 2018 bring to notice various structural constraints, and the state was unable to prepare for this natural disaster or climate change shock. The policies and institutional frameworks were inadequate for managing and monitoring the critical natural resources like land and water; there was an absence of risk-informed spatial and sectoral planning policies and frameworks that led to extensive urban sprawl, unmanaged construction in hazard-prone areas, exclusion of disaster risk preparedness in key socio-economic sectors, weak capacity of institutions to anticipate and respond to extreme events, and limited financial resources as well as the absence of ex-ante financing modalities for risk pooling and sharing (Duncombe, 2018, 54). Extensive deforestation in the catchment areas, unrestricted rock mining in sensitive areas, and political over-confidence were the other possible reasons.

Despite the fact that Kerala ranks highly on the Human Development Index (HDI) (SBI, 2019), the floods demonstrated that a high HDI ranking does not necessarily imply development or catastrophe resilience. Disaster resilience must be developed in tandem with development if long-term growth goals are to be realized. For the 2019–2020 fiscal year, the state was placed among the top 10 states in terms of per capita state domestic production. Other indicators and criteria of the human development index place the state on par with many other industrialized countries throughout the world. When compared to other states, the state has scored exceptionally well on a variety of indicators. For example, the state's literacy rate is 94%, compared to the national average of 73%. The country's average life expectancy at birth was 68.8 years in 2013–2017, whereas Kerala at the same time had 75.2 year life expectancy (RBI, 2020, 15–16). Among all the states, it has the highest life expectancy at birth. The state has the lowest infant mortality rate in India, with a rate of only 10 per thousand live births. Kerala has a poverty rate of 7.05%, compared to 21.92% nationally (RBI, 2020, 237–239). According to 2015–2016 data, 99% of households had access to electricity, 98% of households had access to better sanitation facilities, and 94% of households had improved drinking water facilities (Ministry of Health and Family Welfare, 2017, 2–3). The state's sex ratio is the highest in the country at 1084 women per thousand men. Kerala's high literacy rate makes its local government and villagers highly communicative, participative, responsible, and aware. Its economy is the country's thirteenth largest with gross domestic product (GDP) of \$ 104 billion, with a GDP per capita of USD 11,153 (IMF, 2021).

Kerala's high development indicators demonstrate its robust standing in non-disaster situations. A state with such high standards is expected to be able to survive any disaster or crises with resilience and determination. The floods of 2018 in Kerala, the worst since 1924, were unanticipated and unexpected. It revealed several significant flaws in a state that scored high on all human development indicators.

Hazard and Vulnerability Profile of Kerala

Kerala is located on the southwestern part of the Malabar Coast in India. It covers a territory of 38,863 km² (15,005 square miles) and borders Tamil Nadu, Karnataka, Lakshadweep Sea, and Lakshadweep group of Islands (UT) (Azzali et al., 2021, 120). The state, due to its geographical location along the coast and slopes of the Western Ghats, is highly vulnerable to the effects of natural disasters and climate change. According to the Kerala Disaster Management Plan, the state is vulnerable to 39 natural hazards and human-induced hazards. The phenomenon of floods and landslides is reoccurring along the Western Ghats, whereas during summers the drought-like situation is very common in the state. In the summer months due to dry rivers and low water tables, the issue of water scarcity aggravates.

The state also lies in seismic zone III which is an indicator of earthquake vulnerability (Kerala State Disaster Management Authority, 2016, 16). The climate of Kerala state is humid and tropical, and as far as rainfall is concerned, Kerala receives 3000 mm average rainfall. Southwest monsoon is responsible for 80% of the total annual rainfall. Similarly, the high-intensity monsoon storms cause heavy discharges in rivers leading to floods in the state (ENVIS Hub: Kerala state of environment and related issues, 2021). The incidences of biological disasters such as epidemics and pest attack are also on the rise. Fatalities in road and rail accidents, human-induced accidents, lightning, and boat capsizing are high in the state. Soil piping and coastal erosion make the area more vulnerable to hazards and disasters.

Overview of Kerala Floods 2018

Generally, the Monsoon in India arrives when it hits Kerala and moves on further to other states giving relief from the scorching heat. However, the southwest monsoon of 2018 brought disaster in the form of severe floods and rains which resulted in over 433 deaths and affected all the districts of the state (Government of Kerala, 2018). According to the state government, the floods have directly affected one-sixth of the state's population. Consequently, the floods were declared as "calamity of a severe nature" by the Government of India (Special Correspondent, 2018). Out of 1664 villages in 14 districts of Kerala, the calamity destroyed the 1259 villages. About 5.4 million people were affected and 1.4 million people were displaced by this disaster (Government of Kerala, 2018).

As far as rainfall is concerned, Indian Meteorological Data (IMD) showed that Kerala experienced 2346.6 mm of rainfall between starting of June 2018 to 19th of August 2018, which was considerably more than the expected 1649.5 mm (Kerala State Government, 2018).

Table 1 describes the district-wise rainfall in Kerala from 1st June 2018 to 22nd August 2018. The actual rainfall received by the whole state was around 2394.1 mm. On the hilly slopes of the state, due to heavy rainfall, the torrent of water loosened the soil resulting in landslides. Out of 14 districts, about 341 landslides were experienced in 10 districts (Hydrological Studies Organization Hydrology (S) Directorate, 2018).

Causes of Floods

There were various causative factors that prompted the heavy rainfall in Kerala to become a disaster. Several human factors exacerbated the natural causes of torrential rains resulting in the loss of lives, livelihoods, and infrastructure. From June to August 2018, heavy rainfall was the natural causative factor of flooding. The rainfall received by Kerala was about 42% above the normal range (IMD, 2018). Further, the devastating effects of the Kerala floods were compounded by the dams. In Kerala, there are a total of 33 dams, out of which major dams are Idukki Reservoir,

Table 1 District-wise rainfall released from 1st June 2018 to 22nd August 2018

Districts	Normal rainfall (mm)	Actual rainfall (mm)	Departure from normal (%)	
			Percentage (%)	Type of rainfall
Kerala State	1701.4	2394.1	41	Excess
Alappuzha	1380.6	1784	29	Excess
Kannur	2333.2	2573.3	10	Normal
Ernakulum	1680.4	2477.8	47	Excess
Idukki	1851.7	3555.5	92	Large excess
Kasaragode	2609.8	2287.1	-12	Normal
Kollam	1038.9	1579.3	52	Excess
Kottayam	1531.1	2307	51	Excess
Kozhikode	2250.4	2898	29	Excess

Malampuzha Dam, Mullappriyar Dam, Vazhanni Dam, Banasura Sagar Dam, Idamalayar Dam, Meenkara Dam, Chulliyar Dam, Kanjurapuzha Dam, and Pothundi Dam (NDRF, 2018). The state's majority of dams (around 57%) under hydroelectric projects were operated by Kerala State Electricity Board, and the rest were under the irrigation department. Both bodies were concentrated on electricity generation and irrigation rather than flood control measures. The dams were not capable of moderating floods due to a lack of capacity to store water and delay in the rainwater flow from the catchment to the river. The lack of capacity of the state played a crucial role in compounding the devastating effect of disaster and combined with continuous devastation of local water bodies, wetlands, and natural forests. Almost all the dams in Kerala were full by the end of July with no capacity left to store more water. Consequently, the authorities released all the inflows to the downstream river which ended up increasing the proportions of downstream flood disasters (Hydrological Studies Organization Hydrology (S) Directorate, 2018, 3).

Another major cause of floods was the overflow of rivers and blockage of water bodies. During flood time, rivers, namely, Periyar, Bharathapuzha, Pamba, Manimala, Meenachil, Achenkovil, Chalakudy, and Kabini, overflowed and played an important role in causing the Kerala floods. Periyar, the longest river of state with about 50% of the state's cumulative live storage, affected many cities like Kochi, Aluva, Ernakulum, Idukki, Neriamangalam, Kalady, Malayattor, and Thrissur (NDRF, 2018). Rather, poor resource management also added to the fury. An expert panel on Western Ghats Ecology known as "Gadgil Committee" categorized most of the areas hit by monsoons as Ecologically Sensitive Zones (ESZs) (Welankar, 2018).

Madhav Gadgil, a renowned ecologist, was the head of this team. The first report, namely, "Report of the Western Ghats Ecology Expert Panel (WGEEP) Part I," was submitted by the committee to the government in 2011, recommended classifying the stretch of the Western Ghats into three zones (Gadgil Committee, 2011). The committee suggested strict restrictions on activities like mining and quarrying in ESZs. The usage of land for non-forest purposes and allowing high rises in sensitive areas was also suggested to be restricted in the report. Nevertheless, the recommendations were not adopted by Kerala government. According to Gadgil's report, quarrying was one of the major causes of landslides and mudslides (Narayanan, 2018). Additionally, it mentioned the Kerala floods as human-induced calamity where human interventions and intense rainfall made it a serious disaster.

Unplanned and unchecked urbanization, particularly densely populated cities of developing nations, is increasing the devastating effects of disasters. The development of human society leads to inevitable conflicts with nature, the effects of which depend on the use of land and water resources. The rugged eastern highlands that transform as the midlands and as coastal regions make Kerala's landscape spectacular, but it is also vulnerable to natural processes that can lead to disasters. In big cities like Chennai and Mumbai, urbanization with ill-planned drainage systems, improper filling up of ponds, lakes, channels, and floodplains, inadequate waste recycling, and other infrastructure malfunctions are the major causes of floods (Government of Kerala, 2018). As far as the 2018 Kerala floods are concerned, not just urbanization but unscientific use of land and water resources supplemented the severity of damages. Other triggering factors were illegal constructions (constructions without following building bye-laws), unchecked tourism, construction of non-flood resilient dams, and poor river management. Unlike other big rivers (like Narmada, Godavari), Kerala state is having small and narrow rivers. Over time, with the construction of various dams on these rivers, the flow of water into the rivers has been reduced. Due to the shrinking of floodplains, people occupied these areas for constructing infrastructure (like houses, resorts, and other commercial usages) and cultivation. The reckless urban expansion on floodplains destroyed the natural water bodies and flood-buffering forests. Further, constant removal of natural infrastructure and ecological defenses such as forests and wetlands reduced the percolation capacity of soil. The infrastructure was built over floodplains which destroyed the water bodies.

Poor discharge capacities of water bodies were another cause of floods in the state. Kerala is having rivers with steep embankments which are stable to a degree. It seems that the rivers are stable within their bed; however, higher river discharges cause flooding in the region. Although people were ready for limited flooding, they remain unprepared for the extreme floods which occurred in 2018 after the 1924 floods in Kerala. Initially, flooding started with the flood discharge inflow from rivers which was worsened by poor discharge capacities of canals and blockage of discharge at the sea outlets (azhis and pozhis) (SDMA Kerala, 2021). The frequency and magnitude of river floods have been augmented due to the rising frequency of precipitation and heavy rainfall during the monsoon. According to the fifth assessment of the Intergovernmental Panel on Climate Change (IPCC), it is predicted the

average sea-level rise (SLR) will be somewhere around 24–30 cm by 2065 (IPCC, 2021) which will bring drastic uncomfortable changes in the coastal zone. Hence in Kerala, backwater banks, filtration ponds, paddy fields, and other sensitive sections of the coastal region are vulnerable to SLR. Although it is of not much significance for the next planning cycle, it is particularly vital for the long-term scenario spanning over 50 years (UNDP, 2018).

Similarly, the closure of Cochin International Airport for 2 weeks was an example of a lack of awareness regarding disaster risks especially when urban development meets the weather-related vulnerabilities. The airport is constructed on a low plateau, which is merely 420 meters away from the Periyar River (WRI India, 2018). The runways expanded over floodplains, and the river channels of the airport are not ideally located. The total damage to this world's first solar-powered airport was around USD 35 million with the destruction of about 20% of solar panels (WRI India, 2018). Kochi's airport wasn't unique in this aspect. Other airports such as Chennai and Mumbai airports are also situated close to flood plains and river channels and witnessed devastating flooding in the year 2005 and 2015 (WRI India, 2018).

Therefore, the extreme floodings faced by Kerala in the year 2018 were an outcome of various natural and human-induced causative factors. These include high rainfall, overflow of rivers, high spring tides, poor drainage capacity of canals and sea outlets, issues in flood storage capacity in the reservoirs, unplanned urbanization, and poor resource management. Moreover, an effective policy on the management of dams during floods needs to be specified.

Damage and Loss Assessment

The floods of 2018 lead to loss of lives, widespread damage to infrastructure, injuries, and disabilities. People lost their lives in both villages and densely populated cities. The state faced both direct and indirect losses. The quantified losses like the number of deaths, damage to infrastructure, buildings, and natural resources were included under direct losses, whereas indirect losses due to floods included impact on individual's wellbeing like psychological stress and trauma, a decline in revenue, disruptions in the supply chain of goods and services, and impact on the environment including contamination of drinking water, destruction of aquifers, and saltwater intrusion. Substantial loss by way of damage to cultural and religious structures, ecology, and environment including flora and fauna were also reported. For instance, the hamlets where aranmula kannadi (metallic mirror) is manufactured were under flood water for weeks leading to the destruction of equipment and inventory putting into jeopardy the continued manufacturing of this world-renowned GIS-tagged product.

In Kerala, State Government conducted the damage and loss assessment in the form of a memorandum which was submitted to the Central Government. The memorandum apprehended the damage to government assets only with a focus on productive sectors (Walia & Nusrat, 2020). Later, comprehensive damage and loss

assessments focused on the inclusion of social sectors were also carried out by international agencies such as UNDP and the World Bank along with the State Government under the domain of Post-Disaster Needs Assessment (PDNA).

The state submitted an interim memorandum for damages caused by floods and landslides in Kerala from 29 May to 31 July 2018 of USD 117.20 million. Moreover, on the second phase of floods in the state from 1 August to 30 August 2018, an additional memorandum was submitted by the State Government on fresh damages of USD 685.19 million. Therefore, the total amount of damage claimed by the state from the Central Government was USD 820.39 million (State Government of Kerala, 2019). The cumulative damage and loss from both preliminary memorandum and additional memorandum in terms of human fatalities and impact on agriculture, fisheries, and animal husbandry are described as:

- (a) **Human Fatalities:** The landslides and floods of Kerala from 22 May to 29 August 2018 resulted in 433 fatalities including 268 men, 98 women, and 67 children (Government of Kerala, 2018). About 687 square km of land covering 14 districts and 1260 villages out of 1664 villages were affected by the floods.
- (b) **Agriculture:** Around 1,62,660 hectare of spice crops is cultivated by Kerala with a production of 140,000 tons per annum. Nearly 62% of the total spice cultivated area lies in the districts of Idukki and Wayanad only. Incidentally, a high quantum of southwest monsoon was witnessed by these districts in 2018 which destroyed almost all crops (ICAR, 2018).
- (c) **Fisheries and Animal Husbandry:** The floods resulted in the cumulative loss in aquaculture inland capture and fisheries of USD 14.77 million. Simultaneously, important fishing assets such as boats and fishing nets were destroyed. Around 235 boats were fully damaged, whereas 1002 boats were partially damaged (State Relief Commissioner, 2018). The flash floods took the life of 7146 cattle, including 3502 calves, 2994 sheep, and 650 cows and buffalos. Additionally, around 500,792 poultry died in these floods (State Relief Commissioner, 2018, p28).

Post-Disaster Needs Assessments (PDNA)

A post-disaster needs assessment was done by a committee that was commissioned by the Government of Kerala. The PDNA, initiated on 18 September 2018, was jointly approached by International development partners – World Bank, UN, and European Union – for damage and loss assessment and estimation of recovery needs (Government of Kerala, 2018). The PDNA of Kerala Floods was undertaken by the line ministries and 78 experts from international, national, and state-level. Similarly, a Joint Rapid Damage and Needs Assessment (JRDNA) was undertaken by the World Bank and the Asian Development Bank. The JRDNA focused on the damage and recovery needs of infrastructure sectors like transport, power, water resources, and irrigation (Walia & Nusrat, 2020). The PDNA, on the other hand, covered a total

of 15 sectors and cross-cutting issues, an analysis of macroeconomic and human development impact, and recovery strategy. The sectors were housing, land and settlements, health and nutrition, education and child protection, cultural heritage, agriculture, fisheries and livestock, water, sanitation and hygiene, transportation, power, irrigation, other infrastructure, environment, employment and livelihoods, disaster risk reduction, gender and social inclusion, local governance, and integrated water resources management.

The PDNA estimated the total damages of around USD 1.5 billion and total losses of around USD 2.3 billion totalling disaster effects of around USD 3.8 billion (Government of Kerala, 2018). This did not include the damage estimates as per the Joint Rapid Damage and Needs Assessment (JRDNA) carried out by the World Bank and the Asian Development Bank (ADB). The total estimated damage did not cover the damages to private buildings and properties, losses experienced by the private traders and business units, damage and loss suffered by road transport, Kochi airport, and waterways. The damage and loss calculated as 3.8 billion in PDNA report would be much higher if it is reviewed (Government of Kerala, 2018).

An assessment across social, infrastructure, productive, and cross-cutting sectors (public and private sectors) describes that complete recovery requires a total of USD 4.4 billion. The share of estimated total disaster effects among the sectors of social and economic activity shows that the most affected sectors were the infrastructure sector which accounted for 38% of the total disaster effects. This was followed by cross-cutting sectors (27%) followed by social sectors (18%), and finally the productivity sector (17%) (Walia & Nusrat, 2020).

The share of estimated recovery needs among the sectors of social and economic activity showed that the infrastructure sector had the highest recovery needs which accounted for 51% of the total recovery need. This was followed by the social sectors (20%), productive sectors (15%), and finally cross-cutting sectors (14%) (UNDP, 2018).

The memorandum submitted to the Central Government by the State Government estimated the damages to be USD 0.82 billion, whereas the Joint Rapid Disaster Needs Assessment carried out by the World Bank's team of 28 experts estimated damages and losses of around USD 3.65 billion. The UN-led team of 76 experts in their PDNA study estimated the damages and losses to be about USD 3.93 billion. Though, after counting the recovery needs the cost put forward was USD 4.52 billion (Government of Kerala, 2018). Therefore, a need was felt for convergence in the process of damage and loss assessment to facilitate a holistic framework from responding to recovering from any disaster.

Response and Relief

The response includes actions envisioned for limiting injuries, loss of life, and damage to property and the environment that gets impacted during the disaster. In the wake of the Kerala floods, various stakeholders like NDRF, Indian Army, state-led community volunteers, fishermen, women volunteers, non-state actors, and

technological interventions responded to the massive deluge in a very effective manner.

In total, National Disaster Response Force (NDRF) sent 58 teams along with 435 boats for search and rescue, 5 companies of paramilitary forces, armed forces, and coast guards, 40 helicopters, 20 aircraft, 2 ships, and 10 columns of Engineering Task Force (PR Cell, 2018). Similarly, the Indian Army was deeply involved in the rescue and relief operations in Kerala. Under “Operation Madad,” over 23,000 people were rescued by the Indian Army (Indian Navy, 2018). Indian Air Force also provided immediate assistance by carrying out the “Operation Karuna” and Humanitarian Assistance Disaster Relief (HADR) mission (Anand, 2018).

The Kerala State Disaster Management Authority (KSDMA) provided relief assistance in the form of cereals, pulses, drinking water, kerosene, and other life-essential items in the relief camps. The central government under the Pradhan Mantri Awas Yojana (PMAY) sanctioned financial assistance package of USD 84.0 million for providing houses in villages (Walia & Nusrat, 2020). In addition, the package of USD 252 million under Mahatma Gandhi National Rural and Employment Guarantee Scheme (MGNREGA) was also declared by the Ministry of Rural Development for the financial year 2018–2019 (Walia & Nusrat, 2020).

Kerala fought with one of the worst floods in its recent history. Many NGOs lent their support to the worst affected areas by supplying packaged meals and other relief items. Contributing to the rescue, the fishermen came together across the state to rescue those who were in need. A total of 4537 fishermen with 669 boats went out and managed to save at least 65,000 lives. Every element of cost for this rescue activity was born by the Government (State Relief Commissioner, 2018). Women played a crucial role in responding to the disaster, where the workers of *Kudumbashree* which is a state-driven poverty eradication and women empowerment program made efforts to restore normal life in the regions damaged by the disaster (Anandan, 2018).

Information Technology played a vital role in Kerala floods to carry out rescue and relief operations. Keralarescue.in, a web-based application and social media like WhatsApp, was used by government officials and voluntary groups. These helped the rescue personnel to identify the location of victims, camps, and materials desired in the relief camps. The Rebuild Kerala Application (app) was used by the authorities to assess damages caused to houses and buildings (Ajay, 2019, 913). USD 96.29 million was released to 6,87,843 families as immediate relief at the rate of USD 142 per family. A total of 10,50,838 kits having food supplies and 7,24,352 kits containing 22 essential commodities were supplied to people who returned home from relief camps. A total of US\$ 7.215 million was spent on this relief measure (Chief Executive Officer, 2019).

Rehabilitation and Recovery

The Government of Kerala launched an immediate recovery program, utilizing public finances at its disposal. To build a green and resilient Kerala, a comprehensive

and inclusive roadmap was formulated. The Government under the Local Self Government Department established the “Rebuild Kerala Initiative” (RKI). The objective of RKI was to “bring about a perceptible change in the lives and livelihoods of its citizens by adopting higher standards of infrastructure for recovery and reconstruction and to build ecological and technical safeguards so that the restructured assets could better withstand floods in the future” (Department of Local Self Government, Government of Kerala, n.d.). Several major steps for rehabilitation and recovery were taken by different departments of the state. To withstand future disasters, the principle of building a new Kerala as “Nava Keralam” was adopted by the state. The framework of building a green Kerala under the vision Nava Keralam was emphasized on the concept of “Build Back Better and Fast.”

During Kerala floods 2018, the total loss in the agriculture sector was USD 2.66 billion. An amount of USD 2.52 million compensation under the State Crop Insurance Scheme was allotted to 11,718 farmers. An amount of USD 27.68 million was distributed for bond/block renovation and dewatering and repairing water pumping services. Central Government provided USD 13.08 million through the “Mission for Integrated Development of Horticulture (MIDH) Scheme” (Chief Executive Officer, 2019). A total amount of USD 12.88 million compensation was given to vegetable farmers. The Public Works Department (PWD) allocated administrative sanctions worth USD 3.86 billion for works by re-arranging its budgetary resources for that year. In addition to this, for repairing the roads and bridges, the department issued a new Administrative Sanction worth USD 51.94 million. The Urban department accorded USD 16.8 million in 2018–2019 and USD 2.52 million in 2019–2020 for roads to be repaired or reconstructed. Another USD 2.81 million was also allocated for house construction activities (State Relief Commissioner, 2018).

Moreover, wage employment to 14.72 lakh families was provided under Mahatma Gandhi National Rural Employment Guarantee Scheme (MGNREGS). A total of 16.96 lakh individuals were beneficiaries under the scheme. After the floods, new job cards were issued to 82,605 families (Walia & Nusrat, 2020). Despite being severely affected by the disaster, Kerala Water Authority provided water through tankers in all affected areas. USD 135.32 million allotted by the State Plan Fund and State Disaster Management Fund was used to complete 1661 projects. The Disaster Management Department vide GO (MS)No.27/2018/DMD dated 17/12/2018 formulated a new Scheme “Ujjeevani.” This scheme was aimed to provide bank loans for rejuvenating the flood-affected MSME Units and Shops. This scheme envisaged providing margin money up to USD 0.0028 million for a loan taken (State Level Bankers’ Committee Kerala, 2019).

Lessons Learned

Disasters in all forms such as floods, fires, earthquakes, cyclones, or other events, besides the devastation of lives, teach hard lessons. At present, it is imperative to implement these valuable lessons to reduce risk and make resilient communities. It is the weakest point of the management that gets exposed to the occurrence of every

disaster. The vulnerability and weaknesses of Kerala to hazards and disasters was clearly shown in the floods of 2018. The lessons which flew unabated from the disaster were as follows:

Relook into the Land Use Policy and Plan

Land use planning plays a critical role to control floods. In Kerala, the river flows were constrained by uncontrolled sand mining; however, the soil has been weakened due to the rapid spread of high-rise buildings on unstable hill slopes. Land use planning, a nonstructural approach, promotes sensible use of the land along with natural resources by guiding investment to secure community benefits from development. In the 2018 Kerala floods, it was made clear that the land use policy of the state was short-sighted and improper. Therefore, Kerala must improve the land use policy of the state to avoid or mitigate such disasters in future (Mohanti & Sheikh, 2019).

Convergence of Damage and Loss Assessment Techniques

After the deluge in 2018, various damage assessments were carried out. Firstly, the World Bank carried out the Joint Rapid Disaster Needs Assessment (JRDNA) for re-building Kerala, which calculated an amount of USD 3.65 billion. Secondly, an UN-led team carried the Post-Disaster Needs Assessment (PDNA) for USD 3.93 billion. Thirdly, Central Government also submitted a memorandum for immediate relief for 0.82 billion. Hence to facilitate a holistic framework from responding to recovering from any disaster, there is a need for convergence in the process of Damage and Loss Assessment.

Women as Disaster Responders

The potential contributions that women can offer to disaster risk reduction around the world are often overlooked, and their leadership in building community resilience to disasters is hardly highlighted. Women are generally viewed as a more vulnerable group in disasters, but Kerala floods showed that they are effective responders to disastrous events. The example of “Kudumbashree” which is a poverty eradication and women empowerment program of the Government of Kerala can be used as a case study where women have responded to a disaster of such high magnitude in an effective manner.

Build Back Better

Building Back Better (BBB) is an approach to post-disaster recovery that reduces vulnerability to future disasters and builds community resilience to address physical,

social, environmental, and economic vulnerabilities and shocks. The state adopted the principle of rebuilding as “Nava Keralam” to build a new Kerala to withstand future disasters. The advocacy of a new and better Kerala with an emphasis on BBB was accepted and brought into focus after the Kerala floods. The framework for building a Green Kerala was also dedicated to the vision Nava Keralam (New Kerala). There is need to emphasize on Build Back Better but also Safer. Post-2018 floods it cannot be business as usual: to allow continued granite mining in sensitive areas, destruction of trees in the higher reaches, allowing water bodies to be filled up willy-nilly with no corrective action, and illegal construction in violation of the Building Bye-Laws (BBL).

Role of Technology

Technological innovation is bringing digital solutions to sectors that have previously lacked access to technology, including communities. The rapid pace of this change suggests that one of technology’s most meaningful benefits for society may lie in the humanitarian sector, which must reach a large number of people, in remote and dangerous locations, to provide critical resources fast and efficiently. The boom in technology can be used not only in hazard assessments and modelling but also in responding to disasters. The disaster in Kerala highlighted how technology can be used effectively in saving lives as well as garnering support for the disaster survivors. Social media platforms, Facebook posts, Twitter updates, and WhatsApp groups were used to get information quickly. There were various Tweets from disaster survivors stuck in homes and other places which were used by NDRF responders to reach the distressed people. All the team’s commanders working on the ground were in touch through social media with other officials. A 24×7 helpline was also functional at NDRF headquarter to receive the calls of relatives of the stranded persons. Their location and coordinates were shared with the responding agencies. An example is the Online portal KeralaRescue.in which was started to collect donations (to be sent to the CM Disaster Relief Fund), help enlist volunteers, record requests for help, etc. The web-based applications, especially The Rebuild Kerala app, were used by the authorities to assess damages caused to houses and buildings. In many places, locations facilitated by WhatsApp were used as virtual “control rooms.” Many volunteers were mobilized through social media for one-time cleaning operations. It worked as a device to connect to people in need. The Thanal Palliative and Paraplegic Care Society was one of the organizations which were at the front line of the rescue efforts in the district of Ernakulam. With volunteers trained in paramedical care, this organization rescued 160 people with disabilities (PWDs) along with the elderly population.

Effective Dam Management

Various concerns about the function of dams in floods were widely discussed in media. According to reports, floodgates of 22 dams were opened, and warnings were

issued in numerous districts. These dams should have functioned as a defense wall during periods of excessive rainfall and river overflow. Even though rains were light (below normal levels) during that time, the Idukki dam was nearly full by the end of July. When the torrential rains began in August, the nearly full-capacity Idukki had little choice but to release water into the inundated districts. Experts say dam reservoirs required to be substantially empty before the rainy season for dams to successfully manage floods. The lesson learned, however, is that any structure that is built and has the potential to cause harm to people should be assessed, and Emergency Action Plans should be prepared to prevent such problems in the future.

Protection of Ecosystem and Natural Resources

The usefulness of wetlands for flood abatement can result in storing floodwaters and lowering the speed of floodwaters. This action combined with water storage can lower flood heights and reduce the water's destructive potential. The wetlands have become shallower which enhanced the flooding in Kerala (Kumar, 2018). The disaster highlighted the need to stop the encroachment of wetlands and conserve them to battle the fury of floods.

Empowerment of the Community

The community is the first responder to any disaster. Various communities in Kerala had put immense effort during and post-flood restoration. Empowerments of such communities are always a tool to fight against deadly disasters. The fisher folks of Kerala did the biggest rescue across the state. They arrived in boats and spent tireless hours moving people to safety. Though they were offered payment for rescuing people by the administration, they refused to take it. Additionally, the workers of the Kudumbashree poverty eradication and women empowerment program did efforts to restore normal life. Aapda Mitra, a scheme to train community volunteers with skills needed in disaster response, is developed by National Disaster Management Authority in the selected 30 most flood-prone districts of India. This scheme can be used to empower communities like women and fishermen in Kerala to strengthen their hands in facing any eventuality.

Conclusion

Disasters are a constant challenge faced by human civilizations since ancient times. They lead to the loss of lives of humans and cattle; damage many cities, villages, houses, agricultural fields, roads, and various buildings in many countries. There occur huge monetary and humanitarian losses due to these disasters.

The learning from the Kerala floods of 2018 paves the way for a long-term and stable future for the coastal states. To prevent future casualties and to develop a well-

protected and sustainable society, it is vital to implement what we have learned from the Kerala floods 2018. There are some suggestions drawn so that future calamities can be handled in a more prepared manner. It is recommended to make a strict land use policy of the state. There is a need to stop illegal construction and mining in the restricted areas along with the protection of existing flood vulnerable lands of the state. Secondly, considering the vulnerabilities and capacity building in mind, an inclusive approach for all phases of disaster management must be adopted. With the effective role played by women associated with Kudumbashree in disaster response, measures must be taken to mainstreaming all capacities of women into all the disaster-related programs. The fishermen community also rescued people effectively during the floods. By providing proper training and equipment to this community, a professional task force can be organized. Thirdly, during the post-disaster phase of the Kerala floods 2018, technology played an important role. Technology made it much easier to alert people in risk-prone areas and remote areas. Additionally, capacity building of community, awareness generation to safeguard environment, effective dam management, and protection of wetlands are the concern areas where the state has to work extensively and intensively. Fourthly, both human activities and climate change have worsened the nature of hydro-meteorological disasters. It is required to take care of the environment while doing construction activities. Unsustainable developments and lack of preparedness can lead to massive destruction during floods. Finally, for a dam, proper planning and immediate alerts can mitigate the flood induce damages. In the case of wetlands, if they are damaged or converted into cultivated land, the state has to take care of sustainability. There is a need to take forward schemes like “Aapda Mitra” introduced by National Disaster Management Authority. To save people’s lives in a crisis, it is important to provide rescue training, equipment, and proper setup to the volunteers. The loss of 400 lives is a tragedy that could have been prevented with better management.

The lessons learned from the floods in Kerala should be learned and incorporated by all coastal states of India, to ensure that they build a robust disaster management mechanism to face future disasters.

Abstract

Scholars, policymakers, and industries are focusing on disaster resilience as a goal for the country's socioeconomic development. Disaster resilience is defined as the ability to handle and respond effectively in turbulent times. Establishing resiliency is crucial for Micro, Small, and Medium-sized Enterprises' (MSMEs') survival due to their resource-constrained operating style. Indian MSMEs confront a plethora of challenges in the Coronavirus Disease 2019 (COVID-19) scenario, which the government is working to solve through a number of policy initiatives.

In this context, this study aims to look at the repercussions of COVID-19 and its management by MSMEs. The study draws on data from MSME entrepreneurs operating in the Nagpur District of Maharashtra State, India. The study uses qualitative methodology. This study is based on the case study of five MSME units with its in-depth information and the quantitative data that is gathered through an online questionnaire circulated and analyzed to get a detailed picture of the selected MSMEs.

The findings reflected that the MSMEs faced myriad issues following COVID-19 due to their inherent characteristics of small-scale operations, a limited monetary

base, and a confined area of operation. As a result, an appropriate policy framework emphasizing both monetary and governance aspects is required to support MSMEs' organizational resiliency. The study proposes a number of valuable elements in terms of both theoretical and practical implications for disaster resilience building in industries.

Keywords

MSMEs · COVID-19 · Policy · Resilience theory · Entrepreneurial self-efficacy

Introduction

Resilience (an attribute to respond, recover, and adapt to disruptions) has become a buzzword in today's crisis-ridden climate of Coronavirus Disease 2019 (COVID-19). The pandemic outbreaks are not uncommon in human history, and hence, the coronavirus outbreak was not entirely unexpected, yet it took all of us by surprise when it surfaced, resulting in unprecedented global limitations on human activity and the first major global socioeconomic downturn (Economist Intelligence Unit, 2020). The ILO has dubbed the crisis the worst global disaster since the Second World War (2020). The novel virus had a massive implication for human society and specifically demonstrated what occurs when an unprepared entity encounters an attack.

From its first official note in Wuhan on December 29, 2019, to its peak in mid-April 2020, it has been not just about the direct loss of lives (more than 150,000 people died globally), but also about the indirect collapse of major socio-economic systems, resulting in loss of living and destruction of human survival structures. Therefore, one must recognize that the risk posed by COVID-19 is much greater in terms of widespread impacts on various sectors and systems. There is a critical need for ground realizations, lessons, and rational knowledge to enable policymakers to develop verifiable solutions and for aggrieved groups to reassure and build morale in regard to future crises.

The pervasiveness of the COVID-19 pandemic has caused unforeseen distortions in every area of the global economy. Amidst the impact of the pandemic on diverse industries, Micro, Small, and Medium-sized Enterprises (MSMEs) have faced unique challenges that leave them to nothing but be resilient in order to survive. MSMEs have evolved into a growth engine for the national economy throughout the years. This sector creates livelihood opportunities for both skilled and unskilled labor, promotes market sustainability, and contributes to the country's GDP growth. According to estimates for 2019, the MSME sector contributed 29% to India's overall GDP (Agyeya Tripathi, 2020). As a result, during the last few decades, the government has implemented a slew of measures aimed at enhancing the sustainability of MSMEs. With the expansion of MSMEs, the government's emphasis on Make in India and the new objective of creating a \$5 trillion economy by 2025 can be meaningful.

However, COVID-19 has a profound impact on the growth prospects of the Indian MSME sector. Nationwide lockdown, social distancing, and travel restrictions have unprecedented repercussions on MSMEs in the form of business shutdown, worker migration and absenteeism, people losing jobs and livelihood opportunities, and a spiral effect in the sort of slow consumption and sluggish market dynamics. The pandemic rocked the deepest foundations and fundamentally transformed socioeconomic environment of the world having a deep impact on MSME sector.

MSMEs are vulnerable to any crisis since they are resource-constrained, cash economy-dependent, and operate on a small scale. MSMEs, in general, operate on a short-term basis, and as a result, they can only operate for 5–6 months with limited cash. MSMEs' dependence on the cash economy has been adversely affected by the pandemic (Williams & Schaefer, 2013). A survey conducted by the Endurance International Group of 500 Indian MSMEs in June 2020 states that around 60% of MSMEs are shutting their operations and would not return until normalcy is restored (<https://www.financialexpress.com/>). According to another report, the COVID-19 pandemic has reduced MSMEs' earnings by 20–50% (Times of India Report, 2020). The ILO (2020) even anticipated that MSMEs would be one of the sectors that would require severe intervention following the pandemic's devastation.

For MSMEs, any crisis (natural or human induced) often results in uncertainties leading to destruction. This calls for a robust policy response in an influential way so that resiliency among firms can be established and offset the adverse effects of any pandemic outbreak. However, the strategies to promote awareness among MSMEs, facilitate their planning, and increase their abilities for implementing effective actions to adapt to change have received relatively modest attention in the literature despite the significant role these strategies may play in a pandemic response. COVID-19 has introduced unprecedented situations, which have not been experienced by anyone, so everyone is trying to learn, even governments are learning by doing. Hence, it is interesting to examine the impacts of pandemics on MSME sector that makes it obvious that crisis response is a requirement that must be built into the system. However, resilience should evolve from holistic analyses of credible data sources, not from hasty decisions made on the spur of the moment.

Various lines of research have emerged on business disruption and resiliency in India's MSME sector (Sharma & Singhal, 2018). However, no research has examined the impact of the COVID-19 pandemic on the MSMEs in a state of Maharashtra's economy. Moreover, no research has been conducted on the context of business disruptions in combination with techniques for achieving MSME resilience in those conditions. To address these gaps in the literature, this study proposes the research objectives of investigating the MSMEs' business disruptions caused by COVID-19 and their strategies for developing disaster resilience.

This research makes three key contributions. Firstly, it presents empirical insight into the risk and resiliency in times of disaster. To date, there exist a plethora of research on disaster and their impacts on MSMEs (Miklian & Hoelscher, 2021). However, many studies have examined the correlation between risks from crisis and response of businesses. Those that exist usually focused on large firms, in general,

and multinational corporations (MNCs), in particular (Li & Tallman, 2011). Whereas it was proven in various past research and present scenario of COVID-19 that small businesses are far more vulnerable than large firms under different forms of crisis conditions (Adian et al., 2020; Chowdhury, 2011). Moreover, diversified business operations in the MSME sector lead to a wide range of crisis responses, which has become a good stock of knowledge for preparing to respond to the future disasters. By providing ground reality about the resiliency behavior of MSMEs, this study aims to assist policymakers and practitioners in identifying current responses as well as future strategies to respond to the crisis.

In different settings and countries, we get a different definition of MSMEs. For this study, MSMEs are those industries that are defined according to the MSME act, 2006.

The remainder of this chapter is organized as follows. The next section discusses in detail the conceptual background and significant elements affecting the trajectory of risks, resiliency, and MSMEs. Then, the methodology is described in detail, along with a case study of five MSMEs. The discussion and conclusions section highlight the study's major findings.

MSMEs' Risk and Resiliency: Conceptual Background

It is a historical fact that MSMEs are more likely to be hit by natural and human-induced disasters than larger businesses. This has been proven in the past. Small and medium-sized businesses all over the world have been affected by environmental disasters, like the great floods in 1953, Hurricane Katrina in 2005, Thailand floods in 2011, and the Great East Japan Earthquake in 2011. There is enough evidence from previous research to say that small businesses that do not make health-care products often lose more money when there are both man-made and natural disasters (Auzzir et al., 2018). Small businesses have been ruined by disasters like the 1918 influenza pandemic in the United States, SARS, MERS, the 2009 H1N1 swine flu pandemic, the 2014 Ebola outbreak, the avian influenza outbreak, Salmonella infantis, and ZIKA, all of which have been very bad for them.

Until recently, numerous investigations have consistently highlighted the unusual effects of COVID-19 on MSMEs (Bartik et al., 2020; Akpan et al., 2020). The small industrial sector accounts for a significant portion of the \$2.9 trillion indirect economic losses claimed by disaster-hit countries between 1998 and 2017 (UNDRR, 2018). Small businesses are more prone to disasters owing to their unique characteristics, like working with limited cash, having short-term goals, and limited storage capacity. This makes them more vulnerable to crises, especially when natural disasters weaken the country's infrastructure and socioeconomic base. According to the United Nations Development Program (UNDP) in 2020, those who rely on the informal economy lost a lot of money because of COVID-19. The research has extensively shown that when there is a shortage of raw materials and financial flow is restricted in the market, it primarily influences unorganized small enterprises (Auzzir et al., 2018; Chaudhary et al., 2020; Duchek, 2018). In India, a great majority of

unregistered MSMEs operate in an unstructured manner (Abhishek et al., 2020). The COVID-19 pandemic has disrupted supply chains, leading to interruptions in the flow of money, raw materials, and human capital (Akpan et al., 2020), evoking a range of response mechanisms from various types of MSMEs. This response is mostly constrained by their perception of risk and their ability to establish appropriate response mechanisms.

Therefore, risk as a concept has a distinct meaning in the context of MSMEs. In business and organizational research, risk is frequently defined on the basis of deviations from expected results (Miller, 1992) and such accidents that have a negative impact on business activities (Chen et al., 2019). Disruptions of business functions are one type of negative influence that results in unexpected outcomes (Chen et al., 2019; Scholten et al., 2014). In the instance of COVID-19, the risk is both natural and human-induced, resulting in the disruption of MSMEs' business operations. The nationwide lockdown (from March 25 to June 8, 2020) imposed to combat the spread of COVID-19 infections has entirely disrupted India's socioeconomic activity, with MSMEs suffering supply- and demand-side disruptions, resulting in negative growth rates (Abhishek et al., 2020).

According to research, managing disruptions entails overcoming a business's vulnerability to disruptions and developing and implementing solutions for resilience building (Park et al., 2016). In resilience theory, a notion known as "organizational resilience" asserts that an organization can develop its own resilience through the utilization of existing resources and networks (Bastamnia et al., 2017).

Resistant entrepreneurs are found to have features such as developing and exploiting networks of resources, creatively accepting the changes in the world around them and avoiding crises wherever possible (Duchek, 2018). Resilience is defined as the ability to cope with adversity while maintaining a positive outlook on the future (Asgary et al., 2020). The study applies components of resource generation and networking to understand the status of MSMEs in the current COVID-19 pandemic. This approach would allow for the assessment of the applicability of appropriate policies for fostering organizational resilience and ensuring the sustainability of MSME in the post-COVID-19 era.

Methodology

The study applies analytic and descriptive research approaches. By the application of a case study methodology, the study aims to decipher the subtle meanings and provide a comprehensive grasp of a situation of MSMEs in and after COVID-19. Given that the present COVID-19 epidemic is one of a kind and its impacts in the form of normal business flow disruption are peculiar to MSMEs, it seems necessary to apply the method that can facilitate understanding what is going on at the ground level. In this schema, case method seems to be the most appropriate strategy (Yin, 2013; Mohajan, 2018) to investigate the links between crises and resilience management by MSMEs. For organizational research, the case study is a well-accepted research approach. According to Eisenhardt (1989), "[a] analysing data is at the heart

of creating theory from case studies, but it is also the most difficult and least codified component of the process" (p. 539). Hence, to make data analysis in case study research clearer, content analysis is used as an interpretation approach for qualitative interviews and other data sources.

The chapter's analysis is based on the original data collected through personal and telephonic interviews with five MSMEs' entrepreneurs, owners, and managers, who were chosen from a list maintained by the MSME Development Institute (DI) in Nagpur. The interviews were conducted in-person or over the phone with the entrepreneurs that lasted an average of 50 min. The 14 respondents from five MSMEs were interviewed in-depth, resulting in a sufficient amount of information about the variable, namely, the challenges associated with operating in a COVID-19-related scenario and the strategies adopted to overcome the difficulties (Yin, 2013). Apart from that, concerned civil society organizations, NGOs, and government officials were also interviewed to get the real picture. Secondary sources such as scholarly studies, policy briefs, websites and newspapers, online media reportage, press notes, and advisories were analyzed to gain a better grasp of the topics at hand. The online survey was designed to assess the impact of COVID-19 on small enterprises using questionnaires that solicit thoughts and facts. The study used pre-structured closed-ended questions with ranking or score possibilities, as well as open-ended questionnaires. A questionnaire was distributed online or by email to MSMEs in the Indian state of Maharashtra. The questionnaire is divided into three sections. Part A inquires about responder profiles, whereas part B inquires about MSMEs' pre- and post-COVID experiences and disaster response strategies.

Sampling

Purposive sampling was used to establish a representative sample of MSME entrepreneurs who could consult actively and give a wealth of knowledge throughout the COVID-19 epidemic (Williamson, 2006). The enterprises were selected following consultations with officers from the MSME-DI government office to ascertain their current condition of business. Once the initial MSMEs were contacted, the snowball sampling technique was used to collect informative samples that could be valuable for collecting rich data. The research was continued from August 2020 to December 2021. Both online and offline interactions with entrepreneurs, suppliers, and specific clients aided the study in traversing the chain of trade for MSMEs.

Case Study Results and Discussion

Respondent Profile

As seen in Table 1, each of the five MSMEs has been in business for more than 10 years. Maharashtra, India's industrial hub, has the fourth highest concentration of small enterprises in the country, accounting for 8% of the country's 6.3 million MSME base (MSME-annual-report-English, 2020–21). MSMEs in Nagpur regions

are severely affected by the COVID-19 pandemic and required immediate help to regain their strengths to fight back pandemic-generated recession.

COVID-19: Hard Time Resulting in Risks and Disruptions

This section presents the primary finding received from the case study of five MSME firms that reflect upon the impacts of COVID-19 on the MSME sector.

MSMEs are subject to crises and associated hazards, all the more so because they are primarily dependent on short-term goals and locally available resources. As a result, MSMEs have experienced significant losses both during and after the unexpected shutdown imposed in March 2020 to stem the spread of the pandemic. Suddenly, the functioning of the country's social, economic, and political systems was interrupted, leading to the paralysis of the overall industrial sector. What followed was the closure of companies and workplaces, which resulted in worker migration, as well as the entire prohibition of money, people, and resources mobility. Then, beginning in May and early June, the lockdown was gradually lifted but maintained in high-risk zones or "containment" areas. Even after a full year, in May 2021, stagnancy was not fully vanished. Although a complete lockdown was not implemented, certain limits on the market's and commercial entities' normal operation were enforced.

COVID-19 and resultant lockdown have devastating impacts on MSMEs. For example, the entrepreneur of Blush mentioned that "restricted access to your market is a critical limitation that must be rectified promptly or we will perish." In a similar vein, ENaturelife reflects the thoughts: "We are unable to obtain raw materials, and our products are sitting dormant." What do we have left?" Adobe Pvt. Ltd.'s owner is concerned about declining demand in comparison to the firm's existing capacity. "I am quite concerned about my loans, as demand has dwindled. I was unable to earn the amount required to pay my EMIs. I'm considering selling my home in order to save my business." The lockdown and resulting restrictions have exacerbated the challenge of raising working capital for MSMEs' day-to-day operations. For MSMEs, the pandemic's overall scale is evident in disrupting routine company operations and the difficulties of continuing operations with a restricted supply of cash, raw materials, human capital, and physical resources.

According to the International Labour Organization's paper titled "COVID-19 and the world of work: Impact and policy solutions," the COVID-19 has resulted in an economic and labor market shock. It has a dual effect on the supply side (goods and services production) and the demand side (consumption of goods and services). Apart from capital issue, another major problem never ever experienced so severely is the problem of worker migration. Workers' migration from cities to their hometowns triggered a labor shortage. As illustrated through worker's number and statements of entrepreneurs in Table 2, the present number of employees at each firm is around half that of the pre-COVID period. Another critical aspect of the pandemic's impacts on MSMEs is the wise utilization of available staff to ensure continued production effectiveness. Resultantly, it is observed that whatever available workers are engaged in all types of labor without regard for their skill. Additionally, hiring employees to sanitize the premises is another management

Table 2 Employee absenteeism in MSMEs

Firm	Pre-COVID-19	Post-COVID-19	Statements by entrepreneurs/owners from MSMEs
Adobe Pvt. Ltd.	11	8	I have not reduced my employees much as after sometime we will need them. However, some had left the work
Blush	15	3	It is difficult to continue with the business, so there is no other option to cut your cost to get some profit
Cadform	5	3	I am suffering from severe loss of demand for the product. As it is perishable products, I cannot keep on making it. There is low demand, no support nor any kind of help
Dglass Pvt. Ltd.	16	13	My workers are from Bengal and all have returned to their hometown, and now I am not getting skilled worker
ENaturelife (To protect identity, firms are given fictitious names)	19	11	A production of quality products of Ayurveda depends on qualified technicians and now we are not getting that

Source: Interview and survey

concern that adds to the stress already felt by struggling MSMEs. The interesting revelation from the study is that apart from reduction in the number of laborers, certain businesses, such as Dglass Pvt. Ltd., and ENaturelife, are unable to recruit skilled staff. Here, the issue is not so much about labor absenteeism as it is about highly skilled workers. Certain vocations necessitate subject matter expertise and technological ability; for example, Ayurveda products necessitate Ayurvedacharya or expert knowledge of Ayurveda. Similarly, metalwork fabrication requires skilled personnel. Due to lockdowns and labor migration, MSMEs are experiencing a skills scarcity, which has a negative impact on product quality. Whereas for enterprises such as Cadform and Blush, it becomes difficult to operate the business at its previous capacity, and so cost cutting in order to earn a profit has necessitated the decision to lay off some employees.

Another consequence of the pandemic on MSMEs that came from discussions with suppliers and sales representatives is the expiration of products or a reduction in the shelf life of presently available products. In several industries, the product's shelf life is critical to its sale. Since the lockdown was implemented in March 2020, the products have been in retail stores and are nearing their expiration dates. As one of ENaturelife's sales representatives put it, "Ayurvedic products have a limited shelf life; hence, we predict a big expiry of products in the places of trade, such as retail stores, the distributor's warehouse, and even in the company's storage." Furthermore, Cadform's CEO remarked, "Immediately before lockdown, we prepared a big volume of our products as an extended supplier to the restaurants. However, restaurants shuttered without warning and did not reopen for months; as a result,

many of our items expired, and we suffered significant financial losses. We are still grieving over that loss today, as well. And the future is equally uncertain, so we're in a dilemma." This research also corroborates earlier findings, such as those in a report by *The Hindu*, which stated, "According to a recent survey of 5000 MSMEs done by the All India Manufacturers Organization, 71% of MSMEs were unable to pay salaries to their employees in March." Other reports from different parts of India show a similar picture. *Outlook* reported on a research conducted by the Confederation of All India Traders (CAIT), which represents 70 million traders in India, the majority of whom are small and medium-sized enterprises. According to the study, the pandemic has caused traders hardship of around Rs 380 lakh. Scholars studying the economic impact of COVID-19, such as Ray et al., (2021), have also highlighted how the COVID-19 pandemic has disproportionately affected India's already suffering informal labor economy.

The current pandemic period has reduced formal revenue sources to a greater level, resulting in transforming business methods of these firms. Shrinking consumers and dwindling demand are negatively affecting these MSMEs' trading relationships. A significant effect of COVID-19 is the restriction of distributors' and trade partners' functionality. Due to the closure of the majority of outlets, distributors are having difficulty earning enough profit to operate profitably. Due to the limited amount of sales, distributors must spend more than they get in order to distribute products to the market. This has resulted in a decline in MSMEs' networking, which has had an effect on commercial transactions. For example, Dglass Pvt. Ltd. said, "Many of the distributors are not willing to work during Covid-19, as their operation cost is very low and they are not in position to earn for living, forget about the profit." Reduction in return on investment is one of the reasons that has forced many MSMEs to either completely shut their business operations or reduced them to the level that can be managed within the network.

Response Mechanism of MSMEs: Crisis Analysis and Resilience

The COVID-19 has ushered in unprecedented circumstances that are truly putting an entrepreneur's resilience to test. Resilience is the capacity to adjust to change, which needs a fundamental grasp of risk recognition and its consequences to overcome obstacles created by natural or human-caused disasters (Salisu et al., 2020). Extant research shows that a firm's ability to thrive or overcome risky situations depends critically on the ability to demonstrate a high level of resilience in the face of the interactions with the environment (Duchek, 2018). A system is resilient when it can absorb and adapt to substantial external shocks without altering itself and successfully building new structures to survive (Bastamini et al., 2017). The examined MSMEs are quite vocal about their prospects and capacities for overcoming the risks linked with COVID-19 and reviving their businesses in the future. To find solutions, these MSMEs have been restructured to adapt to change. For example, their fundamental goal is to handle the problem in whatever form it takes and establish long-term viability. For example, products usually expire, so firms are concentrating their efforts on obtaining raw materials and making plans for the future, when demand is likely to increase. This applies similarly to other business operations. The

entrepreneur from Dglass noted, “As social distancing norms exist many distributors are having trouble operating their businesses profitably or even earning revenues. Many of them are not going to survive, so we must find other ways to proceed. On the other hand, we hope that the situation will improve in the future. As a result, we must be prepared. Hence, our objective is to discover alternatives, reallocate our resources, and wait for normalcy.” In this moment of distress, many responders have referred to networks as saviors. “We have problems interacting with distributors,” Adobe responded, “but our close business networks have stepped up and assisted us in selling our products.” “Our relatives who are in this industry,” Blush explained, “become my distributors.” Assist me in selling the things that were laying around. I couldn’t find a buyer for my items, and there’s no one in the market who can deliver them to clients. “My local customers spread the word in their neighbourhoods, and I was able to reach out to potential customers and outlets by building a local chain of networks.”

Apart from being aware of the ground reality, resourcefulness is recognized as another critical attribute driving decision-making during times of the COVID-19 crisis. Sustaining a difficult moment requires resourcefulness in terms of social and human capital. Moreover, business integration usually establishes critical ties at the local level in socioeconomic spheres (Doern, 2016). In case of studied cases, it is recognized that the firms who are well connected to their local networks found needed support system to strive over the disaster-ridden time. The findings reveal that firms with strong ties to their local networks received support for working capital, human capital, and networks to manage their business. As the entrepreneur from Dglass Pvt. Ltd. explains, “Because to Covid, our resources dwindled; initially, we were all distraught, but over time, we learned to exist on our own. Like I used a new strategy, such as mobilising local residents to produce capital. I collect a modest amount of money from all my local clients on a monthly basis; I have a factory outlets for garments, so at six-month intervals, I either return the money with specified interest or offer them discounted products from my factory outlet shop. As majority wants to purchase discounted products, I do not require returning money. Moreover, this enables me to raise working capital for my firm. As a result, networks are my saviours during difficult times.”

During lockdown, the breakdown of supply chain relationships and structures has yet to establish a balance, resultantly entrepreneurs are innovating their business operations. Due to financial constraints, they have little choice but to minimize promotional costs in order to remain competitive in the market. As Blush states, “During Covid-19, we have no choice but to survive with the bare necessities. As a result, giving away free things to sustain the relationship is not an option for us.” Manufacturers, for example, used to provide distributors and merchants one or two units for free. They are not in that capacity today, nor do they intend to do that. It is worth noting that long-term relationships have also had downturns during these times. Old business practices have given way to fresh options and techniques that can aid in survival. Moreover, technology has opened up new avenues for marketing and promotion for MSMEs operating on a limited budget. For instance, Blush noted, “in the past, we placed a premium on appeasing wholesalers and identifying new

retailers for our promotional activities; however, in the current environment, we cannot do so due to the uncertainty, therefore we strive to engage with online-available merchants.” Previously, the emphasis was on developing close relationships with retailers; however, COVID-19 has altered much of this practice. Online channels are the most frequently used medium by these small businesses in these alternatives. They have all agreed that they will use Internet platforms to promote their businesses and build relationships with potential buyers and sellers. Earlier research also suggests that entrepreneurs who adapt to change fast are better at accessing the benefits generated due to opportunities the crisis situation encourages (Kurmann et al., 2020).

This study found that entrepreneurs that demonstrate a quality of adapting to their crisis-stricken workplace are more successful in terms of overcoming the crisis. Contrarily, those lacking in these had long-lasting setbacks in their businesses. For instance, a firm such as Abode is experiencing difficulties because of its inability to adapt to changing circumstances. The firm has installed a transformer, which has resulted in an increase in energy use. When product sales grow sluggish, investment in nonessential entities puts additional strain on the firm’s already frail financial state. To preserve a cost-profit ratio, the firm was forced to restrict production to an unsustainable level. Hence, entrepreneurs’ hasty judgments, made without regard for future prospects, have resulted in a massive loss for the firm. In contrast, some entrepreneurs are seen as anticipatory and paying close attention to ground realities. Entrepreneurs from Blush Pvt. Ltd., for example, concurred, “It is critical to make judgments with a stable mind-set. We have not expanded our business in any way.” During the study, a significant difference in decision-making was seen, allowing us to assess the importance of adaptability on the side of the entrepreneur. The most critical aspect of entrepreneurship development is crisis management. As crises frequently result in infrastructure impediments that frequently result in systemic failure, it is crucial for entrepreneurs to be aware of the possible consequences of the methods used to address critical situations. According to risk and resilience research, it is always desirable to learn lessons from the past and adapt them in order to mitigate negative consequences in the future.

Conclusion

This study examines the impact of the COVID-19 pandemic on MSMEs situated in the state of Maharashtra, India. MSMEs are an integral part of the country’s socioeconomic fabric. Thus, it becomes critical to decipher the socioeconomic and livelihood security components of MSMEs in order to give effective policy solutions for resolving such calamitous scenarios. The findings of the study show indisputably that MSMEs that have adapted after a setback have a number of essential attributes that are together referred to as resiliency. Adaptive behavior, self-awareness of organizational capacity, resourcefulness, a desire to build strong social networks, and a positive attitude toward the future were all identified as important attributes. As a result, given the appropriate conditions and supportive settings created by

legislative frameworks, they will excel and overcome the crisis. MSMEs face significant challenges that impede their ability to respond to change during times of crisis. The barriers include the following: (1) insufficient knowledge to address the challenges; (2) inability to analyze and determine cost-effective adaptation measures; (3) inability to gather financial resources; (4) inability to develop technical capacity to implement options; (5) ignorance of available policies and measures; and (6) skepticism regarding social acceptance of adaptation options. In this circumstance, a government policy regime can operate as a catalyst for adaption practices by rewarding investment, providing technical training, supporting resource development, and establishing a platform for the dissemination of information and expertise to MSMEs.

By conducting empirical research on various dimensions of crisis and MSME's resilience, the study enables the identification of critical elements for enhancing resilience among MSMEs, such as entrepreneurial development programs, financial sustainability, resourcefulness, and networking. Thus, it emphasized critical practical indicators that must be considered when developing a policy to assist MSMEs during the COVID-19 crisis.

Abstract

Interest in disaster management is arising as damage caused by disasters increases worldwide. Many countries are severely affected by emerging risks such as COVID-19 and the enlargement of complex disasters. Complexity theory has been applied to explain how events occur through numerous interactions among elements that often occur in a straightforward but complex manner. The power law distribution is considered one of the significant components of the complexity theory. In this study, the power law distribution has been applied to identify the

relationship between the frequency and magnitude of disasters using the official government data between 1957 and 2020 in Korea. Through the estimation of power law coefficients, the level of disaster preparedness of Korea was judged by comparing them with other continents. Moreover, we provide a detailed explanation of the algorithm used for deriving the coefficients of power law distribution. Since extreme catastrophic events are in the long tail of the power law distribution, efforts should be made to have a response system for an event with a very low probability of occurrence but a huge impact.

Keywords

Complexity theory · Power law distribution · Catastrophic event · Disaster risk management system

Introduction

Interest in disasters is rising worldwide as the frequency of major disasters such as disasters caused by natural and industrial hazards, terrorism, and the resulting socio-economic consumption costs increases (Keen & Pakkot, 2011; Roberts, 2009). In addition, disasters in modern society are very different from those in the past, such as the emergence of new disasters (e.g., COVID-19), the increase in complex disasters caused by the interaction of natural and social phenomena, and the higher possibility of large-scale disasters due to climate change. Accordingly, a paradigm shift in disaster management different from the past is essential to cope with recent trends.

Complexity theory was first applied to investigate complex natural phenomena such as meteorology and has been used for explaining various phenomena in complex systems. It has been revealed that multiple phenomena in the complex system follow power law distribution instead of normal distribution (Blank & Solomon, 2000; Gabaix et al., 2003; Faloutsos et al., 1999). As the causes of disasters become more diverse and complex, studies have been conducted to explain disasters using complex systems (Barton et al., 1994; Becerra et al., 2006; Mandelbrot, 1983). Janczura and Weron (2012) and Jo and Ko (2014) revealed that the magnitude and frequency of certain disasters follow the power law measures. However, since these studies are limited to specific disasters, it is unknown whether the frequency and scale of natural and social disasters occurring in a country follow the power law or not.

Complexity theory is helpful in understanding the features of catastrophic disasters having low probability and high impact. Recent studies have revealed that the relation between frequency and damage of disasters caused by natural hazards, such as earthquakes and hurricanes, does not show the normal distribution. Instead, the relation follows the power law distribution, a core characteristic of the complexity theory, which means catastrophic disasters can happen unexpectedly at any time.

The power law distributed disasters have policy implications for improving the national disaster risk management system since most catastrophic events are in the long tail of the power law distribution. Therefore, this study aims to identify the relationship between casualties, property damage, and frequencies of disasters in

the Republic of Korea. After placing the relationship, this study will provide policy recommendations for improving the national disaster risk management system. In this study, disaster damage data from 1957 to 2020 acquired from national statistics in Korea were applied to understand the distribution of disasters caused by natural and social hazards in Korea. If similar data are available, the method provided in this study can be readily applied to other countries as well. For this purpose, a full description of the algorithm used in this study was provided.

Theoretical Background

Complexity Theory

Complexity theory has been applied to explain complex natural phenomena such as meteorology and financial phenomena such as the stock market. For example, biologists have used complexity theory to mathematically describe ecosystems that are nonlinear dynamic systems (Farber, 2003). The theory is also useful in explaining the characteristics of disasters triggered by various and complex causes. As described in the butterfly effect suggested by Lorenz (1963), modern society is connected by complex networks, and thus even a tiny hazard can cause significant damage. In addition, mega-disasters can happen anytime, and secondary emergencies may result in a more severe impact than the primary disaster. Epidemic crises such as COVID-19 and Ebola virus, the 2011 Fukushima nuclear accident in Japan, and the 2011 great flood in Thailand are typical examples of the complex system of disasters in modern society.

The earthquake that occurred in the Tohoku region of Japan on March 11, 2011, was the fourth strongest earthquake in Japan. The massive tsunami and aftershock that occurred at the same time as the earthquake caused more than 20,000 casualties. In addition, the earthquake caused damage to the nearby Fukushima nuclear power plant, resulting in a complex disaster with radioactive leakage. As a result of this accident, the air, soil, sea, and groundwater were exposed to radioactive materials, causing damage to Japanese society.

The 2011 Thailand floods caused great damage within Thailand and damaged the economy of several countries, including neighboring countries. A major flood occurred due to heavy rains for 3 months from the end of July 2011, and it caused the inundation of the central region of Thailand, which forms the industrial backbone of Thailand. Due to this flood, the production line of automobiles and electrical and electronic products was stopped. Since Thailand was the 12th largest automobile producer globally, the damage caused by the flood caused disruptions in supply to major automobile markets such as Japan, Europe, and the United States. In addition, the supply of hard disks became insufficient due to the flooding of hard disk manufacturing plants, which led to a shortage of semiconductor production by Intel. This insufficient production led to a shortage of supply in the global semiconductor market, which caused a rise in computer prices worldwide. This case shows that a disaster in one country can have a global impact.

Pelling (2003) argued that the complexity theory has significant implications for disaster response. For example, emergence, one of the characteristics of complex systems, shows the characteristics of disasters that may occur from unexpected causes (Pelling, 2003). In line with this, Drabek and McEntire (2003) insisted that emergent phenomena also occur during or after a disaster, when people create and change organizations to respond to disaster situations. Furthermore, Beck's (2004) risk society theory and Perrow's (2000) normal accident theory have in common in that they claim that the increase in risk in modern society is related to complex systems. Nonlinearity, self-similarity, fractal, self-organization, and emergent phenomena, which are the core of the complex system, are necessary elements to analyze disaster occurrence patterns and develop an effective response system.

In addition to these features, the power law distribution of disasters is also a feature in contemporary society that disaster study needs to pay attention to. The recent research about power law distributed disasters, such as Kim and Sohn (2018), Janczura and Weron (2012), and Becerra et al. (2006), revealed that the relationship between the frequency and intensity of disasters such as earthquakes and floods can be explained by the power law distribution, which is one of the typical characteristics of complex system. This feature will be explained in more detail in the next chapter.

Power Law Distribution

Recently, several studies have been published that various phenomena in complex systems follow the power law distribution rather than the normal distribution. Complex systems and the distribution of power laws draw much attention in recent research on disasters because disaster is characterized by complexity in which various factors act simultaneously. These characteristics can be expressed using a power law distribution in which the long tail appears (Etkin, 2015). Figure 1 shows the difference between the normal distribution and power law distribution. In the normal distribution, the highest frequency events occur around the mean. In contrast, high magnitude events happen when the frequency is close to the minimum value in the power law distribution. For example, there are several small earthquakes before one big earthquake, and the frequency pattern follows the power law distribution.

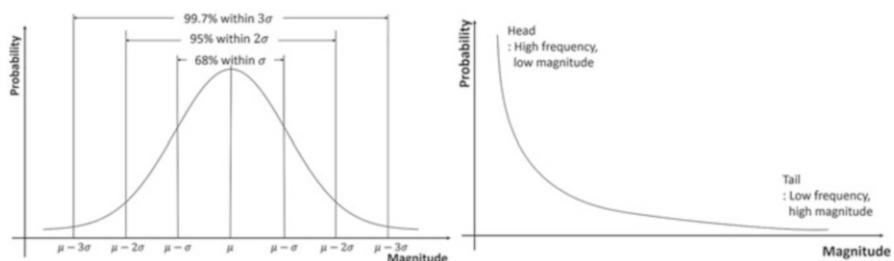

Fig. 1 Normal distribution (left) and power law distribution (right)

Similarly, the city's population, earthquake intensity, and power outage scale follow the power law distribution (Farber, 2003). In this way, it can be said that phenomena following the power law are not characterized by general or mean values (Clauset et al., 2009). Therefore, to prepare for large-scale disasters that do not occur frequently, the analysis should focus on the risks explained by the power law distribution rather than by the normal distribution.

Korean Case of Power Law Distribution

Korea Disaster Data

Disasters targeted in this study are disasters caused by natural and social hazards stipulated in Article 3 of the Framework Act on the Management of Disaster and Safety. In this study, the relationship between the frequency of disasters, personnel damage, and property damage is studied. Personnel damage represents the number of deaths and missing persons, and property damage indicates the amount of economic loss caused by disasters. To conduct the experiment, the number of fatalities and missing people, and the amount of economic loss due to natural and social disasters, was used. In the case of natural disasters, the data provided by the Yearbook of Natural Disaster were used, and in the case of social disasters, the data provided by the Yearbook of Social Disaster (Table 1) were utilized (MOIS, 2021). Data from the 60 Year History of Disaster Management published in 2010 by the former National Emergency Management Agency (NEMA) were used additionally. Finally, the amount of economic loss caused by disasters was converted to the 2020 price index announced by the Bank of Korea to standardize the value at a specific point in time. The conversion equation is shown in Eq. (1).

$$\text{Conversion Index} = \frac{\text{Base year price index}}{\text{2020 price index}} \quad (1)$$

Conversion amount = Conversion index × Won amount

Method to Derive the Coefficients of Power Law Distribution

In this study, the method of Becerra et al. (2006) was used as a model for estimating the relationship between the probability of occurrence of a disaster and the magnitude of a disaster. The probability of occurrence of a disaster can be expressed as Eq. (2).

$$p(x) = 1 - \frac{n(X \leq x)}{N} = \frac{n(X > x)}{N} \quad (2)$$

Table 1 Example of the Yearbook of Social Disaster data

Operation period	Disaster name	Occurring area	Headquarters' installation agency				City, County
			Central Disaster Countermeasures Headquarters	Central Disaster Management Headquarters	Province		
20.1.25. ~ 2.3	Toba pension explosion	161, Ilchul-ro, Donghae city	–	–	Gangwon-do	Donghae city	
20.4.24. ~ 3.10	Andong fire	Mountain 109 Ingeum-ri, Pungcheon, Andong city	–	Korea forest service	Gyeongsangbuk-do	Andong city	
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
20.12.1.	Baekdu Hanyang apartment fire	1119 Baekdu Hanyang apartment, Gumpo city	–	–	–	–	Gumpo city
Casualties							
Sum	Death	Injured	Missing	Amount of damage	Economic loss (Unit: 100 million KRW)	Disaster type	Current disaster management agency Note
7	7	–	–	Partial building loss	0.2	Gas explosion	Ministry of Interior and Safety
8	–	2	6	Fishing boat sinking	3.7	Marine ship accident	Ministry of Oceans and Fisheries
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
11	4	7	–	–	4.3	Multi-dense facility fire	National Fire Agency
							–

Here, X is a random variable of a disaster, x is the amount of damage of the corresponding disaster, $n(X > x)$ is the number of disasters with a scale exceeding x , and N is the total number of disasters. The disaster occurrence probability used in Eq. (2) is not a probability of occurrence for a specific scale disaster but a cumulative sum of the probability of a disaster to occur with a specific scale or larger. In this study, the relationship between the probability of disaster calculated through Eq. (2) and the magnitude was assumed to follow a power law distribution. Accordingly, the probability density function of Eq. (2) can be estimated using a power law given as Eq. (3).

$$p(x) = Cx^{-\alpha} \quad (3)$$

Here, $p(x)$ decreases as x increases, and α is a coefficient indicating the degree of decrease. In addition, C is a constant to make the maximum value of the cumulative probability function to 1. C is calculated in two different ways as shown in Eq. (4), depending on the case where the data used is continuous or discrete.

$$\begin{aligned} C &= (\alpha - 1)x_{\min}^{\alpha-1} = \frac{1}{\zeta(\alpha, x_{\min})} \text{ (Continuous)} \\ &= \frac{1}{\sum_{n=0}^{\infty} (n + x_{\min})^{-\alpha}} \text{ (Discrete)} \end{aligned} \quad (4)$$

The value to be estimated in the model of Eq. (3) is x_{\min} and α , which indicates the minimum value of the interval starting to follow the power law and the degree to which it decreases, respectively. In order to simultaneously estimate x_{\min} and α , the value of x_{\min} is sequentially increased during the estimation of α , and the suitability of the estimated x_{\min} and α value was tested using Kolmogorov-Smirnov statistics. When representing the graphic results, logarithm scale is taken because the number of deaths and the minimum and maximum values of the damage have a very wide range. By taking logarithm of the probability of occurrence according to the magnitude of the disaster, Eq. (3) can be converted into a linear equation as shown in Eq. (5), and the two variables following the power law show a linear relationship on the log-log graph.

$$\log p(x) = C - \alpha \log x \quad (5)$$

Program Implementation

To implement the program utilized in this study, it is required to organize the disaster data first. The natural disaster data and the social disaster data provided from the Yearbook of Natural Disaster and Yearbook of Social Disaster, respectively, must be sorted in a single Excel file along with the data from 60 Year History of Disaster

Table 2 The input file format used in the calculation of power law coefficients

Year	Start point	End point	Disaster type	Disaster detail	Cause	Personnel damage	Property damage (unit: 1000 KRW)	Property damage (converted)	Source
1957	1957 0806	1957 0806	Natural	Heavy rain	Heavy rain in Nakdong River	–	54,200,000	2,477,265,200	60 year history of disaster management
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
1998	1998 1029	1998 1029	Human-induced	Fire	Fire at Beomchang cold plaza	27	330,520	374,810	Yearbook of social disaster
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
2020	2020 0319	2020 0320	Natural	Forest fire	Ulju-gun Forest fire	2	2,800,000	2,800,000	Yearbook of natural disaster

Management. The types of information included in the input Excel file are year, starting date, ending date, type of disaster, whether it is a natural disaster or social disaster, disaster type in detail (e.g., flood, fire), cause of the disaster, number of personnel damage, amount of property damage, property damage converted to a specific point of time, and the source of the data (Table 2). In the case of natural disasters, the frequency of disasters was analyzed with respect to death toll and the amount of economic loss, while for social disasters, occurrence frequency was examined only with the number of casualties.

Figure 2 shows the pseudocode for calculating the coefficients explained in Eqs. (1) to (5). By reading the input data in a similar format as shown in Table 2, the user then selects the type of analysis. The corresponding data is extracted from the input file and sorted in ascending order for power law estimation according to the selection. The parameters of estimation x_{min} , α , C are performed by iteration of gradually increasing the value of x_{min} . At each iteration, the corresponding α value is calculated and the suitability of x_{min} and α are verified by Kolmogorov-Smirnov test. After the iteration process, the correction coefficient value C is computed according to the corresponding case from Eq. (4), depending on whether the damage data is continuous or discrete. The algorithm can be readily applied to countries with similar data to derive the relationship between the scale of disaster damage and disaster frequency.

Results

To analyze the relationship between the damage and the frequency of natural and social disasters in Korea using power law distribution, disaster damage data between 1957 and 2020 were utilized. The data was classified into natural and social disasters, and each disaster's property damage was converted into economic value

Power Law Analysis Program

Input : Disaster data input excel file(Table 2)

Output: Power law estimation parameters(x_{min}, α, C), plot of power law estimation

- 1) **Read input file**
input_file.xlsx
- 2) **Select analysis type**
 - case 1 = "natural disaster" & "property damage"
 - case 2 = "natural disaster" & "personnel damage"
 - case 3 = "social disaster" & "personnel damage"
- 3) **Get data for corresponding case**
 - if case 1:
indexes = find("natural disaster" from 4th column of input file)
take corresponding values from 9th column of input file
for i ∈ indexes:
 data = input_file(i, 9)
 - if case 2:
indexes = find("natural disaster" from 4th column of input file)
take corresponding values from 7th column of input file
for i ∈ indexes:
 data = input_file(i, 7)
 - else case 3:
indexes = find("social disaster" from 4th column of input file)
take corresponding values from 7th column of input file
for i ∈ indexes:
 data = input_file(i, 7)
- 4) **Estimate power law analysis parameters(x_{min}, α, C)**
 - Sort data by ascending order
 - if case 1(continuous case):
 - for idx in range 1:length(data):
 gradually increase x_{min}
 estimate α using direct MLE(maximum likelihood estimation)
 check suitability of x_{min} and α by Kolmogorov-Smirnov test
 - get correction coefficient $C = \frac{1}{\zeta(\alpha, x_{min})}$
 - else case 2 | case 3(discrete case):
 - for idx in range 1:length(data):
 gradually increase x_{min}
 estimate α using direct MLE(maximum likelihood estimation)
 check suitability of x_{min} and α by Kolmogorov-Smirnov test
 - get correction coefficient $C = \frac{1}{\sum_{n=0}^{\infty} (n+x_{min})^{-\alpha}}$
- 5) **Plot power law analysis**
Plot with estimated parameters(x_{min}, α, C)

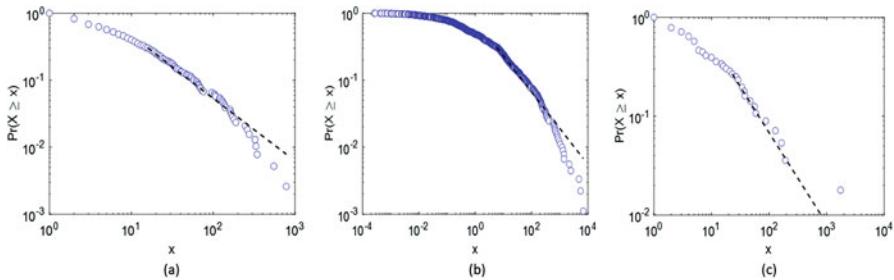

Fig. 2 Pseudocode of power law analysis program

in 2020. Assuming the relationship between the magnitude of the disaster and the probability of occurrence follows the power law as shown in Eq. (3), x_{min} and α values were estimated. In the case of the number of personnel damage, it has a discrete characteristic in which values are an integer, while the amount of property damage is continuous data with decimal points. Equation (4) was applied to obtain the correction constant C .

Table 3 and Fig. 3 show the results of estimating the relationship between the disaster damage magnitude and the frequency of the corresponding disaster using the power law distribution. Table 3 shows the values of x_{min} , α , and C obtained through the estimation procedure. Figure 3 shows the difference between the actual

Table 3 Estimated parameters of power law analysis

	Natural disaster			Social disaster		
	x_{\min}	α	C	α	x_{\min}	C
Personnel damage	16	1.93	-565.9087	23	1.92	-79.3563
Property damage	5,803,300	1.5408	-1451.7677			

**Fig. 3** (a): Relationship between frequency of natural disasters and casualties, (b): relationship between frequency of natural disasters and economic loss, (c): relationship between frequency of social disasters and casualties

probability of the disasters and the estimated probability of occurrence. In Fig. 3, the circles represent the value using the actual frequencies of disasters and the dashed lines represent the estimated frequencies. Figures 3(a) and (b) show the probability of occurrence according to the size of economic loss and the number of personnel damage caused by natural disasters, respectively. Figure 3(c) shows the probability of occurrence according to the number of personnel damage due to social disasters. In most cases, the estimates and the actual frequencies of disaster match well, confirming our basic assumption that the frequency and magnitude of disaster follow the power law distribution. In the case of economic loss caused by natural disasters, the estimated probability tended to be overestimated compared to the actual probability of occurrence.

The α value of the estimated from power law distribution indicates the degree to which the probability of occurrence decreases according to the magnitude of the disaster. If the value of α is large, the probability of occurrence decreases rapidly compared to the magnitude of the disaster. If the value of α is small, the probability of occurrence decreases gradually compared to the magnitude of the disaster, indicating a relatively vulnerable state. In Korea, the α value between the number of the death toll and the probability of occurrence of natural disasters was 1.93. Becerra et al. (2006) analyzed the α value for each continent using the same analysis method (world average, 1.73; North America, 2.13; South America, 1.68; Asia-Oceania, 1.69; Africa, 1.66; EU, 1.73). Since the α value in Korea is relatively high compared to other continents, it can be argued that the level of preparation for natural disasters in Korea is relatively high concerning the death toll, even with high population density. The high α value in North America can be explained due to the high-income level, high level of disaster preparedness, and low population

density. On the other hand, EU countries with high-income levels similar to North America showed a low α value of 1.73, similar to that of low-income countries. This result may be due to the very high population density of European countries.

Conclusion

This study analyzed the relationship between the frequency of natural and social disasters and the degree of damage using official damage data published by the Korean government. The statistical distribution of natural and social disasters that occurred in Korea from 1957 to 2020 follows the power law distribution. The result indicates that a paradigm in the national disaster response system must be re-established to efficiently respond to these large-magnitude disasters. Specifically, our results were compared with those of Becerra et al. (2006), which applied the same model to analyze the relationship between the number of casualties from natural disasters around the world. The resulting α value in Korea was high at 1.93, indicating the degree to which the probability of occurrence decreases according to the scale of disasters. Our study identified that the level of preparation for natural disasters in Korea is relatively high concerning the death toll, even with high population density.

Policy makers dealing with social issues, such as welfare and education, tend to focus on the issues located in the average zone because most demands are concentrated on average events. However, in the case of disasters, extreme events, sometimes considered anomalies, have a more significant impact than average events. That is, the extreme catastrophic events are in the long tail of the power law distribution. Therefore, it is necessary to have a response system for an event that has a very low probability of occurrence but has a huge impact. To this end, efforts should be made to establish an inclusive risk governance system in which all stakeholders, including the central government, local government, and civic groups, participate and to allocate sufficient budget and manpower. Creating a safe and resilient country is possible only when the efforts and aspirations of every citizen are combined and continuous efforts are made.

Abstract

Disaster response planning has progressed substantially; however, it remains frustratingly bogged down as some major impacts were not anticipated. The traditional disaster response method of predicting risks in advance and executing it in an emergency has progressed substantially. However, recent catastrophic events, such as the 2011 East Japan earthquake and the ongoing COVID-19

pandemic implied that modern society is getting vulnerable to disaster due to the increasing features of complexity, interconnectedness, and uncertainty, which often results in unexpected or emerging risk. To respond well to these unexpected events, this study explored the emergence of systemic disaster risk resulting from risk environment and its change by the intersection with response measures. As a result, the authors proposed a multi-dimensional systemic response framework, consisting in risk management flow, strategic response map, and multi-dimensional emergency planning, which can help countries respond effectively to the systemic disaster risk that threatens the safety of modern society. The response framework adopts the notions of risk types from a response perspective, anticipated risk, emerging risk, amplified risk, lingering risk, and mitigated risk, and applies the risk management flow to address various risks in an emergency.

Systemic disaster risk · Response management · Risk management flow · Multi-dimensional systemic response framework

Introduction

The enormous damage caused by large-scale disasters, such as the 2011 Thai flood, the 2011 East Japan earthquake, and COVID-19, reminded us that understanding the nature of disaster risk is critical for establishing an effective response system since this type of event is often not anticipated in the classical risk analysis. The World Health Organization (WHO) announced that the number of confirmed cases of COVID-19 reached 659,108,952 as of January 10, 2023, among which the number of deaths was 6,684,756. On top of that, COVID-19 has had a systemic impact on all sectors worldwide. For example, the economic indicators recorded the deepest global recession since the end of World War II, and it was expected for a 100 million additional children to fall below the minimum proficiency level.

The traditional way to respond to disasters is to probabilistically predict risks in advance through the identification of hazards, vulnerabilities, and exposures and to respond by establishing a response plan (IRGC, 2018). Implementation of well-planned countermeasures by trained and responsible authorities can effectively reduce most conventional risks. However, unexpected risks often appear and cause huge damage due to increasing tendencies in modern society, such as complexity, interconnectedness, and uncertainty. Clearly, there are ripple effects on the rest of society and its response mechanism which are related to the interconnectedness permanently increasing interdependence of modern society. Therefore, the effective response system for disaster risk in modern society should be established based on the analysis of the dynamic process of risk change.

This chapter aims to investigate the nature of systemic risk and the evolutionary process of risk and identify key lessons that political leaders and emergency managers can apply during crises. Finally, the authors propose a multi-dimensional

response framework to systemic disaster risk. Section “[Evolution of Systemic Approach for Disaster Risk Management](#)” explores academic and practical achievements in understanding the features of systemic disaster risk. The authors explore the concept of systemic risk in line with the Sendai Framework for Disaster Risk Reduction (SFDRR), the concept of the black swan and cascading disasters, and the systemic approach in safety science. Section “[Understanding the Features of Systemic Disaster Risk for Response Management](#)” investigates the features of systemic risk and its cases and identifies notions of risk types. Section “[Multi-dimensional Systemic Response Framework](#)” proposes a multi-dimensional response management framework, which consist in risk management flow, strategic response map, and a multi-dimensional emergency plan.

Evolution of Systemic Approach for Disaster Risk Management

Understanding Risk in Line with Sendai Framework for Disaster Risk Reduction

The Sendai Framework for Disaster Risk Reduction 2015–2030 (Sendai Framework) was adopted at the 2015 Third UN World Conference on Disaster Risk Reduction (WCDRR) to replace the Hyogo Framework for Action 2005–2015: Building the Resilience of Nations and Communities to Disasters (HFA). Based on the evaluation and review of the implementation of the HFA, the Sendai Framework suggested new strategies and action-oriented elements in order to cope with all types of disasters regardless of the size, frequency, and progression of damage (UNISDR, 2015). While the HFA emphasized the effect of disaster risk reduction (DRR) on the development and poverty eradication, each nation’s responsibility for DRR, the need for support for developing countries vulnerable to natural disasters, and the importance of international cooperation (UNISDR, 2007), the Sendai Framework aims to comprehensively understand and manage disaster risk in all dimensions of hazard, vulnerability, and exposure as well as to strengthen the disaster risk governance (UNISDR, 2015). To this end, the Sendai Framework adopted the four priorities: understanding disaster risk, strengthening disaster risk governance, investing in DRR for resilience, and improving disaster preparedness and building back better (UNISDR, 2015).

As emphasized in the Sendai Framework, an effective disaster risk management should be based on understanding the risk at all levels of vulnerability, capacity, exposure to people and assets, hazard characteristics, and the environment. In this sense, the 2019 Global Assessment Report on DRR investigated the endeavor and progress in understanding and managing systemic risks. The report found that great progress has been achieved in previous decades in identifying risks related to specific hazards. However, it also insisted that assessing systemic risk should be done through a comprehensive and multidisciplinary approach. This has an important policy implication for designing effective response system. Assessing disaster risk focusing on specific hazard is not enough for coping with the systemic risk in

modern society since large-scale disasters often occur by the intersection of various system elements. It requires an engagement of a multitude of expertise from all fields of knowledge and all sectors of society.

Black Swan and Cascading Disasters

To prepare a response plan for catastrophic events having low frequency and high impact became an emerging issue in crisis and emergency management. Recent research found that the magnitude of damage and the frequency of disasters follow the power-law distribution and that the catastrophic events are in the long tail of the power-law distribution. Nassim Taleb called these catastrophic events “Black Swan,” which, judging by our limited experience, are unlikely to occur (Taleb, 2007). These extreme events were also referred to as “Dragon King” by French physicist Didier Sornette. He argued that these events are so extreme and different from small events that accompany them (Sornette, 2009). Since Dragon Kings do not occur frequently, it is very hard to standardize the response method, resulting in the difficulty in allocating required resources in advance.

Pescaroli and Alexander improved the conceptualization of catastrophic events having low frequency and high impact by focusing on the systemic environment in which these catastrophic events occur. They emphasized the need to respond to cascading disasters where the cascading effect is increasing and the secondary emergencies have a much stronger impact. Based on the investigation of various catastrophic events along with their cascading effects and vulnerability paths, they defined cascading disasters as “extreme events, in which cascading effects increase in progression over time and generate unexpected secondary events of strong impact” (Pescaroli & Alexander, 2015). Some cascading disasters can be more easily anticipated even in a complicated situation. For example, a major earthquake on a known fault may generate a tsunami that will displace populations, create a health crisis (overwhelming hospitals and causing epidemic), and cause socioeconomic problems (unemployment and intrafamilial violence). Many cascading disasters are more challenging to foresee, especially in a complex system. The difficulties of responding to those cascading disasters in complex systems may arise from the nonlinearity (e.g., the fear of a few persons can generate the entire group to completely irrational behaviors), the emergence (e.g., the sudden need of a very specific equipment such as a respiration may trigger a new response), and the interdependence (e.g., one ship in the Suez Canal blocked 13.5% of global goods for weeks with ripple effects for months).

Normal Accident and Systemic Approach in Safety Science

Perrow (1984) investigated the Three Mile Island accident that happened in 1979 at the nuclear power plant located in Pennsylvania and found that complex systems, such as nuclear power plants, hold a high probability of unavoidable accidents, called normal accidents, regardless of safety measures and devices. He insisted that a

system accident or normal accident may involves the unanticipated interaction of multiple failures, reflecting the characteristics of high-risk systems (Perrow, 1984). According to Perrow, accidents in modern society are closely related to complex technical and mechanical structures with embedded risks in our lives. In a highly complex system, individual technologies interact closely and inseparably through an endless loop. This complex system is prone to catastrophe whenever one of the interwoven elements becomes dysfunctional. Also, in tightly coupled systems, a disaster can be caused by complex interactions in which a ripple effect spreads due to a series of errors when a single element fails. The normal accident theory has an important policy implication for response management since it understands the systemic risk as a matter of organizational characteristics embedded in a societal system. The normal accident theory contributed to understanding the occurrence of accidents and human behavior patterns in the context of complex social-technical systems and influenced AcciMap, System-Theoretic Accident Model and Processes (STAMP), and Functional Resonance Analysis Method (FRAM) that tried to interpret accident analysis as a systemic model. The remarkable feature of the systemic approach is that it does not generate a specialized “accident model” consisting of defects and failures to find the cause of the accident. Neither system operates to cause an accident, nor does it interact to cause an accident at the moment when an accident happens. The system may deviate from the norm while functions interact to maintain the system, rather than failures are caused by the interaction of faults. Understanding system as a whole is another feature of the systemic approach.

Jens Rasmussen was a pioneering scholar who took a systematic approach for accident analysis. The research by Rasmussen and his colleagues is at the forefront of a new perspective on understanding “error” in that it “emphasizes the role of a wide range of environmental and political factors as well as organizational problems in the process of elucidating the cause of an accident” (Waterson et al., 2017). He advocates a shift of focus from the error to the dynamic interactions and mechanisms leading up to the error. Rasmussen illustrates this with his dynamic safety model of three boundaries forming a safety envelope that constitutes the workspace within which the system can work safely. The three boundaries are the boundary to economic failure, the boundary to unacceptable workload, and the boundary of functionally acceptable performance or the boundary to performance failure.

The main concepts of the “dynamic safety model” and the “risk management framework” proposed by Rasmussen are reflected in the AcciMap. The AcciMap shows the causes of accidents hierarchically according to the hierarchy of causality. The most direct cause (e.g., the subject of an accident or the condition of its occurrence) is indicated at the bottom, and the most fundamental but indirect reason (e.g., government regulation or political/social environment, etc.) is displayed at the top. It analyzes the cause of an accident according to the hierarchy, including government (e.g., political science, law, economics, sociology), regulators and associations, company, management, staff, and work (Rasmussen, 1997; Rasmussen & Svedung, 2000). The advantage of AcciMap is to find problems of the overall system and come up with solutions for improvement by linking the various factors that influence the occurrence of the accident into a single logical diagram.

In 2004, Leveson presented the System-Theoretic Accident Model and Processes (STAMP). The model describes systems as a “hierarchy of control based on adaptive feedback mechanisms” and explains how a failure to control system safety produces accidents in design and operation. Leveson’s STAMP adopted AcciMap’s hierarchy and regarded the system as the framework of the control system. The basic principle is that all systems have a built-in control relationship. STAMP assumes that if the control is done correctly, an accident does not occur, and if an accident occurs, a problem can be found in the control relationship. Leveson understands the system as a multilayered control structure based on an adaptive feedback mechanism. STAMP regards an accident as a matter of “control” rather than a matter of “failure.” It views an accident as a process in which several events are continuously and dynamically combined. In other words, in complex and intensive modern systems, accidents can occur even by the interaction between safe elements, and thus Leveson emphasizes that the focus of accident analysis should be on “securing the dynamic stability of the system” rather than “preventing failure” (Leveson, 2004, 2011). Since STAMP emphasizes hierarchical control to ensure the safety of system operation, it underlines that field workers and all actors, including related safety managers, executives, and politicians, participate in safety management. Therefore, it can identify complex accident causes that the existing linear causal model cannot explain.

In 2004, Hollnagel introduced the Functional Resonance Analysis Method (FRAM), which graphically illustrates systems as a collection of interrelated sub-systems and functions that perform at variant degrees. And when those variants’ resonance merge, they produce an emergent variation that is uncontrollable. Hollnagel’s FRAM takes functionality as its core concept, arguing that the system’s functions interact. FRAM focuses on finding out what is necessary for a system to operate well and which functions had not been implemented when an accident occurred (Hollnagel, 2012).

The four basic principles of FRAM are failure and success equivalence, approximate adjustment, emergence, and functional resonance. First, the equivalence principle of failure and success means that failure and success do not have different origins but that things can go well or go wrong for the same reason. Second, the principle of approximate adjustment is that the performance of social and technological systems, including individual humans or groups, is adjusted to external environmental conditions. Third, many consequences that appear suddenly or whose causes are unknown can be explained as emergencies. Finally, the relationship and interdependence between functions within a system should be understood as arising from functional resonance in a specific situation (Hollnagel, 2004). To explain the relationship between complex system functions, Hollnagel identifies the relationship and connectivity between functions through the following six elements: Input (I), Output (O), Preconditions (P), Resources (R), and Time (T), Control (C). FRAM tries to figure out which functions are essential through these six elements, how those functions should be performed, and if the functions were not performed in a specific situation, why they were not performed. The results of the analysis indicate what must be done to remain safe in the future. Analysis by FRAM does not start with finding the direct cause of the accident but with finding which function must be

performed. If such a function was not performed well, it tries to explain why it was not performed (Hollnagel, 2004).

The advantages of the systemic model gave the following implications to the multi-dimensional systemic response framework. First, the hierarchical structure in the AcciMap and STAMP implies that the systemic response measures should have hierarchical structures. Response policy should be set up in the central level where the roles of primary agency and support agencies are clearly delineated, and in the local level, the response measures should be implemented in a timely way through one united agency. Second, the interconnection between functions in the FRAM has the implications that the response strategy should consider the intersection between risk environment, risk type, and response measure. Third, it is crucial to find hidden risks by focusing on securing system functionality, rather than continuously chase failures.

Understanding the Features of Systemic Disaster Risk for Response Management

Concept of Systemic Disaster Risk

Studies on systemic risk and cascading disasters have been actively conducted in the DRR academia and the UN system. The investigation related them with complex networks and their association with an increasingly interconnected world (Pescaroli et al., 2018). COVID-19, which has hit the world from 2019 to the present, is characterized by a lack of knowledge about the virus, complex socioeconomic impacts, and high uncertainty due to a second emergency with high impact. COVID-19 has also affected several sectors, such as economic downturn, reduced educational opportunities, food security issues, and protection of human rights (United Nations, 2020). The recent accomplishment about the conceptualization of systemic risk was achieved by the Global Assessment Report on Disaster Risk Reduction 2019 (GAR 2019), which explored the nature of systemic risk in combination with the complex networks and increasingly interconnected world (McGlade et al., 2019). The GAR 2019 defined the systemic risk as “risk that is endogenous to, or embedded in, a system that is not itself considered to be a risk and is therefore not generally tracked or managed, but which is understood through systems analysis to have a latent or cumulative risk potential to negatively impact overall system performance when some characteristics of the system change” (UNDRR, 2019).

Schweizer and Renn (2019) explored the nature of systemic risk and suggested its five core elements: complex characteristics, having a transboundary effect, a stochastic relation between the triggers and their effects, a nonlinear relation including tipping points, and often being underestimated by policy makers and the citizen. This concept considers that when a problem occurs in one element or cluster of a system, it causes a chain failure in other elements or clusters in the system. A risk becomes systemic when a society’s essential systems, such as critical infrastructures and healthcare system, are potentially threatened (OECD, 2003). This cascading effect

can cause a severe error of the system or lead to a situation in which the entire system fails.

The COVID-19 pandemic made clear that viruses can be potential risk drivers for health systems and at the same time can threaten multiple other systems. The pandemic has systemic features. It generated a health crisis, but also triggered an economic crisis, an environmental crisis, and a humanitarian crisis (UNDRR, 2021). In addition to healthcare, COVID-19 affected all those systems upon which society depends on, including transport, energy, telecommunications, information management, trade, health, finance, education, chain supply, etc. In addition, the pandemic risk can be intersected with natural events, such as climate change and natural disasters. Nuclear accidents, which can release radioactivity along with damage to the plant systems and potentially impact the broader economy and public health, have been recognized as a typical “systemic risk” and have been discussed as the leading topic in disaster risk reduction and response management (Robin & Anne, 2012). The nuclear industry has always considered many dimensions of safety-related risk to prevent nuclear accidents, and the integrated risk management approach has been factored into the design and operation of nuclear power plants under these high safety standards. And the approach to risk management in the nuclear industry has evolved to become more reliable based on probabilistic risk modeling and lessons learned from the previous few accidents (IAEA, 2001). The nuclear sector has adopted a systematic approach to identifying the potential risks and finding strategies to manage the risk, and these strategies include a design with a conservative safety margin and backup system, high-tech, and safety culture, etc. along with an independent regulatory framework.

Based on the review of previous research and concept in various sectors including UNDRR, the authors found out that the systemic disaster risk is highly likely to cause the failure of the system as a whole due to a series of complex cascading interaction and that the likelihood of the catastrophic events can be described as a function among systemic disaster risk, response management and the threshold of the society. Therefore, this study conceptualizes the systemic disaster risk as the likelihood of a large-scale loss of life, injury, or destroyed or damaged assets in a system, society or a community as a result of the variability in the functioning of system elements and/or the interaction between elements in the society.

Notions of Risk Types for Systemic Response Management

From the response management perspective, disaster risk can be categorized into five types: anticipated risk (AtR), emerging risk (ER), amplified risk (ApR), lingering risk (LR), and mitigated risk (MR). Since this category was developed based on the study of systemic risk by UNDRR and academia, it can be applied to systemic disaster risk irrespective of hazard type. First, the AtR can be assessed qualitatively or probabilistically as a function of hazard, vulnerability, exposure, and capacities of the society. In general, the responsible authorities prepare response plans based on the anticipated scenario and implement standard operating procedure through

precise situational awareness. Next, ER is seldomly described in the disaster response plan, and thus the responsible authorities have difficulties in coping with the ER. At the very early stage, the ER is mainly caused by insufficient information and complexity, which often causes situational awareness error. It can be caused by societal endogenous factors, originating in ecology and socioeconomic or cultural behavior. Additionally, ER may occur when appropriate response measures reduce the target risk but create new types of risk in a highly connected society. Strengthened social distancing, for example, reduces the risk of infection, but leads to economic stagnation and weakened education. The third risk type is ApR that emerges because of inappropriate response measures. The inappropriateness may come from mal preparedness, such as an insufficient resource by lack of skilled responders, delayed execution due to a situational awareness error, and complex socioeconomic impacts by the original risk. The responsible authorities should pay very special attention to ER and ApR since such risk is highly likely to bring about cascading disasters, which may result in a national crisis. Fourth, LR is sustained when the pre-planned response measure does not mitigate all the target risk. LR needs to be monitored closely by the responsible authorities because it may cause a huge impact when coupled with certain conditions. The last one is MR, which is the objective of multi-dimensional systemic response. The best scenario for response management is to mitigate the original risk by taking all available response measures at the very earliest stage. However, there are increasing trends that original risk does not dissipate and becomes worsened or new types of risk emerge in a tightly interacting and interconnected society. To mitigate these types of risk, the responsible authorities must not stick to the existing plan but take an adaptive response by adjusting the response plan and mobilizing all available resources under a higher political leadership (Table 1).

Table 1 Risk types and their features from a response management point of view

Risk type	Features
Anticipated risk (AtR)	Assessed qualitatively or probabilistically before the event Used to define the scope of a disaster response plan Necessitate the implementation of pre-planned response measure in case of emergency
Emerging risk (ER)	Not described in the response plan and, due to the high uncertainty and novelty, hardly anticipated at the initial stage Occurs due to endogenous factor and/or when appropriate response measure mitigates the target risk, but creates new risk while coupled with high uncertainty, interconnectivity, and complexity of the society Necessitate the early assessment, rapid re-planning, and adaptive response
Amplified risk (ApR)	Results from the implementation of inappropriate countermeasures Necessitate early assessment, rapid re-planning, and adaptive response
Lingering risk (LR)	Remains even after the countermeasures were taken Necessitate close monitoring and adaptive response as needed
Mitigated risk (MR)	Goal of the multi-dimensional systemic response

Multi-dimensional Systemic Response Framework

This chapter proposes a multi-dimensional systemic risk response framework that political leaders and emergency planners can use to prepare well and respond effectively to catastrophic events and cascading disasters caused by systemic risk. The framework consists of five core elements: (a) identifying risk management flows and its components of risk environment, risk types, and appropriate response measures, (b) developing a strategic response map, (c) developing a multi-dimensional emergency plan using RMF and SRM, (d) applying the multi-dimensional systemic response to cascading disasters, and (e) taking the pre-planned and/or adoptive response measure at a very early stage and according to situational change and risk flow.

Identify Risk Management Flow

This effective response system requires a clear understanding of what types of risk appear due to the risk environment comprising hazard, vulnerability, exposure, and other features of the society and how those risks have been changed by the interventions with the responsible authorities and citizens. Kim et al. (2021) developed the concept of the risk management flow to help political leaders and emergency planners identify the risk environment, risk types, and the appropriate response measures systematically. In the study of Korea's response to COVID-19, Kim et al. (2021) stated that the risk environment should include not only traditional elements of hazard, vulnerability, and exposure but also high uncertainty, interconnectivity, and complexity of the society. The study also found that various types of risks, such as emerging risk and amplified risk, had appeared and been affected, for better or worse, by the response measures taken by the affected society (Kim et al., 2021). The risk management flow (Fig. 1) shows that the risk environment, risk

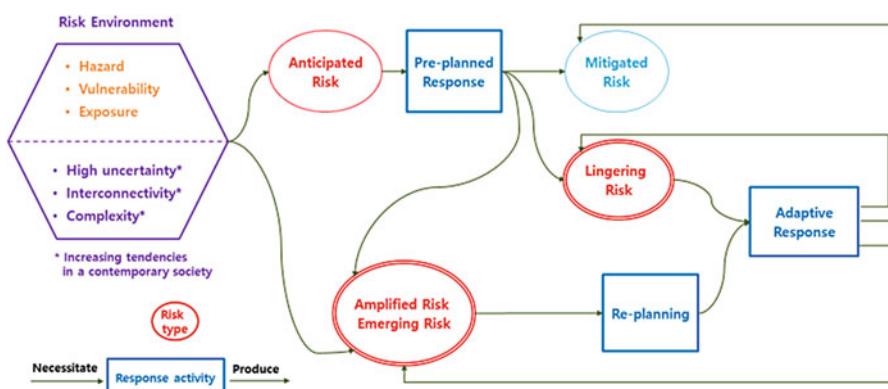

Fig. 1 Risk management flow revised from Kim et al. (2021)

types, and response measures are related nonlinearly and illustrates which risks emerge from the risk environment and how those risks are affected, better or worse, by the response measures.

The conventional risk management is to assess risk probabilistically by estimating hazard, vulnerability, and exposure. Such well-defined risk works as a strong basis for disaster response plan. However, the increasing features of modern society, such as high uncertainty, interconnectivity, and complexity, tend to generate unanticipated risk that cannot be dealt with by the pre-planned response measures. Therefore, the risk environment for systemic disaster risk should consider both the increasing features and conventional risk factors, such as hazard, vulnerability, and exposure.

Develop Strategic Response Map Using Risk Management Flow

The first step is to predict and draw anticipated risk (AtR) from the risk environment composed of risk factors, hazard, vulnerability, exposure, etc. AtR is a risk that can be determined in advance by analyzing past similar events and scientific knowledge and often work for a basic guideline for developing a disaster response plan. The second step is to estimate the emerging risk (ER) of which the probability is unknown. In general, ER has not been seen in the past. ER refers to a risk that is impossible or unnecessary to allocate resources in advance because the occurrence is unpredictable or extremely unlikely. However, its secondary emergency is severe unless it is tackled by appropriate measures.

The next step is to derive the response measures necessary to deal with ER and AtR that may appear early and then connect them with the corresponding risk. Response measure means the actions to be performed to reduce the risk in the organizational unit. In general, response measures need to be described in the form of a verb. For example, when there is a risk of the influx of a new coronavirus from overseas countries, the appropriate response measures are to strengthen the monitoring of inbound travelers at the airport and to operate an emergency response center. The response measures for ER and AtR occurring at the early stage are often different. ER requires either modifying the existing plan to match reality or finding and implementing an entirely new response plan since there is no pre-prepared response plan. For AtR, the responsible authorities should promptly implement pre-planned response measures that were described in the disaster response plan and mastered through training.

The response measures implemented to cope with ER and AtR produce the four results. First, if an appropriate response measure is implemented in a timely manner by mobilizing sufficient human and financial resources and equipment, the situation is terminated by reducing the risk according to the best-case scenario set in the disaster response plan. However, the responsible authorities should be prepared for the possibility that the best-case scenario will not work out. The initial response may be delayed or a response measure that is not suitable for risk resolution may be implemented. This often occurs in situations where situational awareness errors are

likely to occur due to insufficient information in the initial phase. For example, in the early stages of COVID-19, the infected continued to engage in social activities without being informed by the responsible authorities, which resulted in a wider spread of the new virus. This was caused by a lack of information and high uncertainty of the hazard. If such an inappropriate response is implemented, the risk will likely be amplified. This second result type may cause a severe secondary emergency, and thus an adaptive response should be made by quickly modifying the existing plan. Third, response measures reduce the target risk but may create new risk when it is closely coupled with complexity, interconnectivity, and high uncertainty of the society. For example, strengthening social distancing may lead to an economic downturn while reducing the infection risk. The responsible authorities should monitor these unanticipated risks when implementing the countermeasures and take rapid action when the new risk emerges. Finally, responsible authorities should prepare for the situation that the implemented response measure has been effective to some extent and the risk is partially mitigated. Lingering risk by itself does not cause much damage, but it can cause significant damage if conditions are met at some point. The responsible authorities should not estimate the situation optimistically but should find lingering risks and implement adaptive measures to mitigate them. Figures 2 and 3 exemplify the application of the strategic response map to two systemic disaster risk: pandemic crisis and nuclear power plant accident.

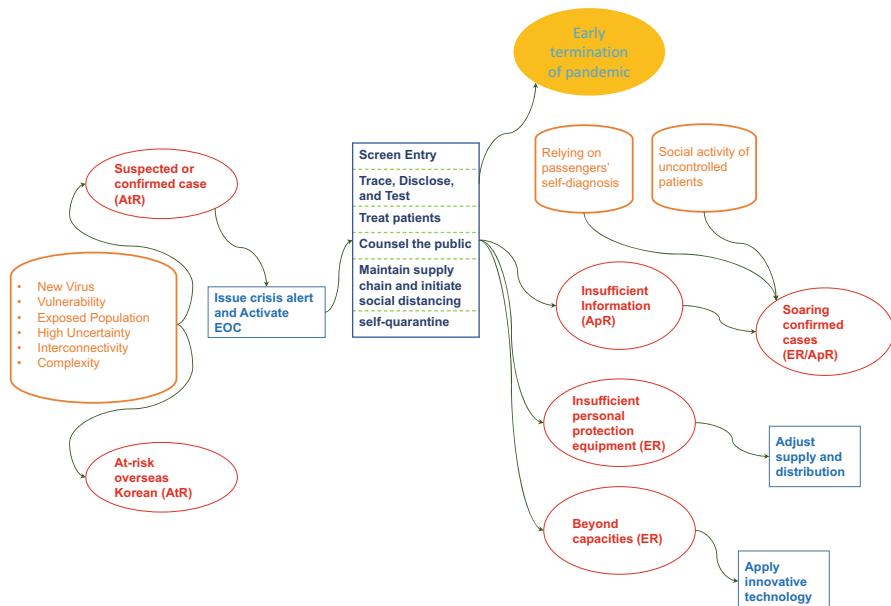

Fig. 2 Strategic response map for pandemic crisis retrieved from Kim et al. (2022)

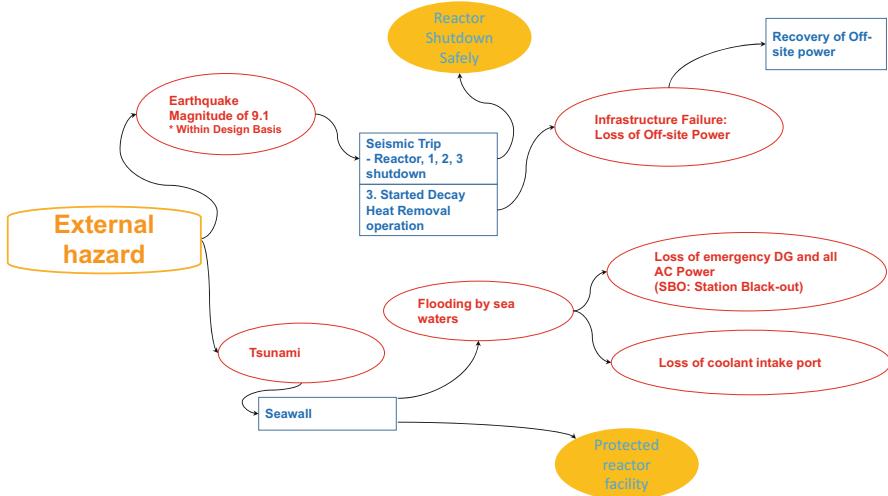

Fig. 3 Strategic response map for nuclear power plant accident

Develop a Multi-dimensional Emergency Plan Using RMF and SRM

To properly apply the SRM to the actual situation requires clear roles and responsibilities, necessary resource allocation, repeated training and mastery, and a legal and institutional environment to be equipped before the event. On top of this, the capability to flexibly modify the response plan needs to be cultivated in the training process when the real-world case does not go as planned due to the increasing features of contemporary society, such as complexity, interconnectedness, and uncertainty. The extent of damage or disaster pattern is often determined by how to respond in the early stage. The responsible authorities, including the primary agency and all support agencies, should develop emergency operation plans that include the requirements presented above and train themselves assuming real situations. In this multi-dimensional emergency plan using SRM, response measures should include the following four dimensions: actions, responsible authorities, resources, and enabling environment. These four elements included in the RM must be completed by the primary agency and all support agencies, such as the Ministry of National Defense and the National Police Agency, respectively. The countermeasure means pre-planned policies to mitigate the predicted risk. The countermeasure in general needs to be taken by the primary responsible agency. Next, the responsible authorities should be described, including the primary agency to take the countermeasure and all support agencies. The resource include equipment, financial resource, and an expert list, which needs to be allocated to implement the countermeasure. Finally, the emergency plan should include the legal base for implementing countermeasures and allocating resources.

Conclusion

Disaster response planning has progressed substantially; however, it remains frustratingly bogged down as some major impacts were not anticipated, resulting in millions affected by the 2011 Thai flood, the 2011 East Japan earthquake, the 2010 Haiti earthquake, and the ongoing COVID-19 pandemic. The traditional disaster response method is to analyze risk factors and vulnerabilities, predict risks in advance, establish a response plan, and execute it in case of an emergency. The prompt implementation of the planned countermeasures by the responding agency is effective in reducing most risks and can be realized by response manuals and trained responders. However, the modern society see the increasing features of complexity, interconnectedness, and uncertainty, which often results in unexpected or emerging risk.

This study aimed to improve the response management by better anticipating unexpected impacts which will increase as modern society becomes even more interconnected and interdependent. To this end, the authors proposed a multi-dimensional systemic response framework, consisting in risk management flow, strategic response map, and multi-dimensional emergency planning, which can help countries respond effectively to the systemic disaster risk that threatens the safety of modern society. The response framework adopts the notions of risk types from a response perspective, anticipated risk, emerging risk, amplified risk, lingering risk, and mitigated risk, and applies the risk management flow to address various risks in an emergency.

Developing strategic response map and multi-dimensional emergency plan and applying the response framework in a national crisis will help countries prepare for and respond to systemic disaster risk, which will result in reducing the uncertainty of disaster response. The authors hope that political leaders and emergency managers will use the multi-dimensional systemic response framework to identify emerging issues, make evidence-based decisions, and integrate administrative efforts through democratic processes.

Abstract

Disasters have been regarded as a source of lesson-drawing and major driver of policy change. This study aims to propose a policy change model related to catastrophic events and test its usefulness. The PCAD model suggested in this study can handle dynamic interactions among various actors. The authors applied the PCAD model to the five cases of policy change in Korea and the United States and identified four policy lessons. First, policy change after disasters is likely to happen by the interaction of the following four streams: citizens' interest and demand for institutional reform, problem identification, political leadership, and administrative effort. Second, large-scale disasters do not necessarily entail changes in disaster response organizations and laws. Disaster response organizations and laws can be improved only when the citizens, governments, politicians, and the media pursue change with a strong will. Third, in general, policy changes cannot solve all the problems embedded in the society, implying that vulnerability remains and thus a catastrophic event can occur when certain conditions are met. Finally, the government should prioritize enhancing the national disaster response system so that it can appropriately respond to all types of risks.

Policy change · Major disaster · PCAD · Institutional form

Introduction

Catastrophic events causing tremendous casualties and property loss are likely to bring about a national crisis. In other perspectives, they can provide an opportunity to lead policy changes for resilience building by enhancing disaster-related laws and strengthening organizations for disaster risk management. Policy change takes various forms, ranging from an intense form, including the constitutional amendment or the enactment of laws, to a slightly weak form, such as the behavioral change of public officials and the change of administrative order.

A large-scale disaster tends to bring about media attention and citizen's request to improve the disaster risk management system. The typical examples include the establishment of the Department of Homeland Security after the September 11 terrorist attacks in 2001, the strengthening of FEMA's roles and responsibilities after Hurricane Katrina in 2005, and the establishment of the Ministry of Public Safety and Security after the Sewol sinking accident in 2014 in the Republic of Korea. However, all the attention and requests do not lead to policy change. When the attention and requests are supported by enabling environments, such as administrative efforts and political will, policy change tends to happen.

Some academic achievements are Birkland's Event-Related Policy Learning model, Kingdon's Multiple Streams Framework model, and Kim's Disaster-Triggered Policy Change model. Based on these achievements, this chapter aims

to investigate the policy change process in the wake of major disasters, and to draw policy implications that each government can apply to establish a sound disaster risk management system based on the lessons from major disasters.

A Conceptual Framework for Policy Change in the Wake of Major Disasters

Policy Change, Window of Policy, and Focusing Events

Policy change refers to recognizing the problems of existing policies and environmental changes, preparing policy alternatives, going through the policy agenda formation process, and then modifying and confirming a policy alternative. Factors that promote policy change include changes in the policy environment, changes in public demand, and unexpected events. On the other hand, factors that hinder policy change include psychological resistance, political coalition against change, political burden, and high cost.

Policy change has diverse types. The most apparent form of policy change is the revision of a constitution, the drafting of significant laws, or the complete revision of existing acts. Weak forms of policy change include changes in the behavior of “street-level bureaucrats” or amendments to regulations. The representative models to explain policy change include Hofferbert’s Policy Output Change Framework (POCF), Sabatier’s Advocacy Coalition Framework (ACF), Hall’s Paradigm Change Framework, Kingdon’s Policy Stream Framework (PSF), Birkland’s Event-Related Policy Learning (ERPL) model, and Kim’s Disaster-Triggered Policy Change (DPC) model. Among the various policy change models, this study focuses on the research of Kingdon, Birkland, and Kim since these models are suitable for analyzing the policy change process that occurs because of the interaction between several factors that occur after a major disaster. Etkin (2014) argued that when a major disaster happens, the interest and criticism of the public, the media, and the National Assembly explode, and policy changes occur through the appearance and interaction of numerous policy alternatives and many players. He also insisted that the Garbage Can Model (GCM) suggested by Cohen et al. (1972) could explain this process precisely.

Kingdon proposed the PSF model to better explain the roles according to the interests of various participants by further enhancing the GCM. Since Kingdon proposed the PSF, also known as the “policy window” theory, as a model for policy agenda-setting, the model has been applied to various areas, such as policy change, policy formation, policy execution, and policy evaluation. Policy change occurs when the three flows of policy problems, politics, and policy alternatives are combined while flowing independently according to their own rules. Kingdon argued that a policy window would open during the flow of three streams when a dramatic event and a political event occur in the process of the three streams and act as a triggering device. When each stream develops independently and combines at critical junctures, this combination creates an agenda change (Kingdon, 2010). The

problem stream refers to the interest of government officials on various issues (Kingdon, 2010). The flow of politics consists of the national mood, public opinion, election results, change of administration, partial or ideological distribution within the parliament, and pressure from interest groups (Kingdon, 2010). Politics has a strong influence on setting new agendas (Kingdon, 2010). Policy alternative flow refers to the process in which various policy alternatives are established through the policy community, including researchers, parliamentary staff, planning, evaluation and budget office staff, and interest group analysts (Kingdon, 2010). The policy window opens for a short time when the conditions for putting a given topic on the policy agenda are met (Kingdon, 2010). A significant change in public policy can happen when such a policy window opens (Kingdon, 2010).

To explain the triggering impact of policy change, Kingdon (1995) introduced the concept of a focusing event on the study of the agenda-setting phase of public policy. He insisted that social shock events including crises and disasters should be an essential factor inducing policy change. Kingdon's study on policy change including the concept of policy window, multiple streams, and focusing event laid the foundation on the research of institutional reform and legal enhancement in the wake of major disasters by Birkland and Kim. Birkland (1997, 2006) applied the concept of focusing events on disasters and accidents and found that the focusing event could affect the setting of the agenda. Birkland (1997, 2006) insisted that a focusing event, such as a major disaster, could function as a triggering device, influencing policy flow by attracting attention to ideas that were not formed before the event. He also argued that a new opportunity could occur to review policies considered politically unappetizing or unnecessary. Birkland analyzed whether disasters could cause policy change beyond agenda change and how much their impact would be. He found that policy change might be triggered by focusing events, such as major accidents, natural disasters, and catastrophes due to terrorist attacks. He also proposed the concept of "potential focusing event," noting that a disaster does not necessarily lead to policy changes that the possibility relies on various conditions.

The ERPL model proposed by Birkland (2006) assumes a linear relationship that goes through the following stages: the occurrence of an event, increased agenda attention, group mobilization, discussion of ideas, and adoption of a new policy while considering the possibility of learning outcomes being forgotten (Sapat et al., 2011; Birkland, 2009). He analyzed the process of the establishment of the Department of Homeland Security after 9/11 through the ERPL model. After the 9/11 terrorist attack, the focusing event and interest in an agenda based on safety, such as homeland, aviation, and cyber safety, increased. The report of the Hart-Rudman Committee was adopted, which included the concept of homeland security by collecting opinions from various sectors of society. Afterward, the Department of Homeland Security was established by integrating the core functions of improving aviation security and improving confidentiality and information sharing, border patrol, and the Immigration and Naturalization Service.

Kim (2018) found that the magnitude of disasters, such as death tolls and property loss, and their frequency followed the power-law distribution by analyzing a total of 1019 disasters that occurred in Korea from 1948 to 2015. Among 1019 disasters, the

number of potential focusing events was 38 and focusing events were recorded to 22. He also found that all the catastrophic events causing huge human loss were in the long tail of the power-law distribution. In addition, Kim (2018) scrutinized how large-scale disasters affected the change of disaster-related laws and organizations coordinating disaster risk management in Korea. To this end, he referred to Birkland's argument that the learning process takes place in the executive and legislative branches after a focusing event like a large-scale disaster. The possibility of policy change increases because of this learning. He also referred to Kingdon's multi-stream concept, considering policy change because of the interaction of various flows that occur after a large-scale disaster.

By using these concepts, he analyzed the process of improving disaster-related laws and emergency response institutions after the collapse of the Seongsu Bridge in 1994 and the collapse of the Sampoong Department Store in 1995. On October 21, 1994, the Seongsu Bridge in Seoul collapsed, resulting in 49 casualties. The day after the accident, President Kim ordered the revision of the construction-related laws and the expulsion of the insolvent construction company. Three days after the accident, President Kim issued a special discourse apologizing to the public. The National Assembly enacted the Special Act on Safety Management of Facilities (Act No. 4922) on January 5, 1995, as a result of various debates about the measures to prevent a recurrence. The government implemented safety inspections on public facilities, including all the bridges across the Han River, and conducted reinforcement work for aging facilities (Kim and Sohn, 2018).

On June 29, 1995, the Sampoong Department Store located in Seoul collapsed, resulting in 1439 casualties (502 dead and 937 injured) (NEMA, 2009). After the collapse of the Sampoong Department Store, President Kim declared the site and the surrounding area as a special disaster zone and promised to establish a safety culture and expel poor construction. The National Assembly held a special committee to investigate the accident 2 weeks after the accident, adopted the state investigation plan for the Sampoong Department Store collapse, and conducted a state investigation (July 12, 1995–August 11, 1995).

The frequent occurrence of large-scale accidents in the 1990s increased public interest in technological disasters. Reflecting this, on July 18, 1995, the Disaster Management Act was enacted to manage human-caused disasters comprehensively. On October 19, 1995, an organization dedicated to human-caused disasters was established in the Ministry of Home Affairs and the rescue organization was strengthened.

KL's Policy Change After Disaster (PCAD) Model

This study proposes a Policy Change After Disaster (PCAD) model to explain the dynamic interactions of various elements in the wake of a catastrophic event, leading to a policy change, such as institutional reform and legal enhancement. The model was developed based on the achievements by Kingdon, Birkland, and Kim, which includes a window of policy, focusing event, and risk environment. Using the PCAD

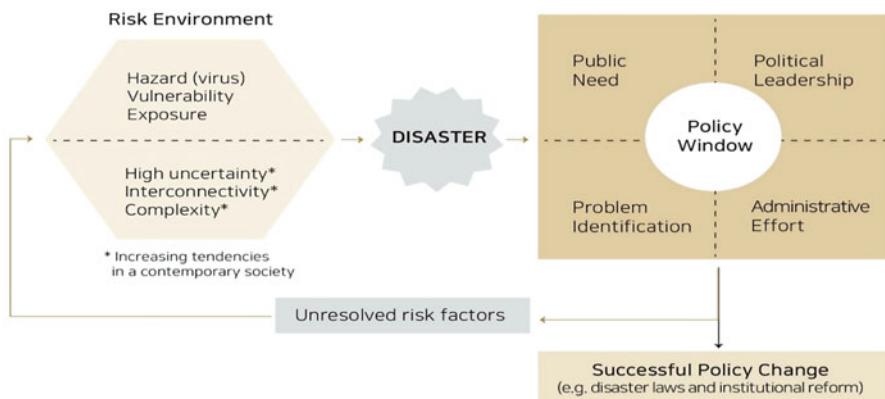

Fig. 1 Policy change after disaster model

model, the authors investigated the improvement of disaster risk management institutions and disaster-related laws after Typhoon Rusa (2002), Typhoon Maemi (2003), Daegu subway fire (2003), and Sewol Ferry sinking accident (2014). Based on the study, the authors insist that after a catastrophic event, the public need, political leadership, administrative effort, and problem identification arise. The policy window opens, resulting in the change of organizations and laws for enhancing disaster risk management. More specifically, a catastrophic event is highly likely to happen when natural, technological, or social hazards are coupled with vulnerable environments, such as a population concentrated in a low-lying river basin, a mal-constructed building(s), and settlements in areas at risk of landslides. Such a large-scale disaster draws the public's attention and increases the interest of the media, which would be followed by the flow of politics such as the President's special statements and firm instructions, the urging of the National Assembly for improvement measures, the flow of policy alternatives including the activities of the Prime Minister or related ministers, the preparation of the government's improvement measures, and the flow of problem including audit reports and investigations on the cause of accidents. Policy changes occur as a window of policy opens and improvement measures are adopted and implemented. Since such a policy change cannot solve all problems, the vulnerable factors remain and trigger a focusing event when certain conditions are met. Therefore, continuous monitoring of weak factors and activities to increase society's resilience is needed. Figure 1 shows the Policy Change After Disaster (PCAD) model developed by Kim and Lee.

In August 2002, Typhoon Rusa caused property damage of KRW 6.1 trillion and 270 casualties, the largest damage to Korea since Typhoon Sarah in 1959 (NEMA, 2009). The very next year, in September 2003, Typhoon Maemi, which recorded the lowest central atmospheric pressure of 950 hPa since Korea's meteorological observations, caused property damage of KRW 4.4 trillion and 148 deaths and missing persons (NEMA, 2009). On February 18, 2003, a large-scale fire caused by arson occurred in the Daegu subway, causing 192 death, 21 missing, and 151 injured. The

authors investigated how the changes in disaster risk management policy had been affected by public needs, problem identification, political leadership, and administrative effort that the PCAD model identified as critical elements for policy change in the wake of catastrophic events.

Public Need

As Typhoon Rusa was expected to make landfall, 7 cases were reported before the disaster, 26 cases during the disaster stage, and a total of 299 cases after the disaster. In the case of Typhoon Maemi, 56 cases were reported during the typhoon period and 129 cases during the week after the typhoon occurred. This increase in media reports shows that Typhoon Rusa and Typhoon Maemi were the subjects of social attention.

When the Daegu subway fire accident occurred on February 18, 2003, all broadcasting stations delivered breaking news and broadcasted the situation. On the day of the accident, 60% of the news reported the accident as a distinctive feature. From February 18, 2003, to March 4, 2003, significant broadcasters reported the accident a total of 457 times. Among them, 140 cases (20.4%) of accident investigation, 97 cases (20.4%) of safety measures, 85 cases (17.9%) of human casualties, and 40 cases (8.4%) of other subjects were recorded. This showed the high demand of the public for the improvement of managing human-caused disasters (Song & Lee, 2003).

Problem Identification

Several organizations, including the Board of Audit and Inspection, analyzed the reasons for the large-scale damage caused by Typhoon Rusa and Typhoon Maemi. The investigation reports included organizational problems such as insufficient coordination of disaster management along with technical problems such as the insufficient implementation of measures to secure dam safety in preparation for extreme weather events, the poor flood control policies, and regulations related to river zones (Board of Audit and Inspection of Korea, 2003a). The report of the Board of Audit and Inspection on the Daegu subway fire analyzed that several complex factors, such as insufficient disaster management system, insufficient morality of train manufacturers and supervisors, lack of training of train crew, and inferior flame retardancy performance of interior materials of trains, interacted and brought about the catastrophic impact (Board of Audit and Inspection of Korea, 2003b).

Political Leadership

When Typhoon Rusa started a path of destruction, President Kim held an emergency ministerial meeting to designate the area damaged by the typhoon as a special

disaster area and restore the damage as soon as possible. When massive damage occurred due to the Daegu subway fire (February 2003) and Typhoon Maemi (September 2003), the President ordered a rapid restoration of the damage and improvement of the disaster management system.

In the National Assembly, after the Typhoon Rusa, Typhoon Maemi, and Daegu subway fire, a special committee was formed and operated to find out the cause of the damage and requested the government to take measures to prevent the recurrence of the damage as soon as possible.

Administrative Effort

After Typhoon Rusa, the Daegu subway fire, and Typhoon Maemi, the government closely cooperated with the affected local governments to provide central support for damage management and prepared a plan for improving the disaster risk management system to prevent the recurrence of accidents. To prepare measures to prevent repeated floods every year, the Flood Damage Prevention Countermeasures Planning Group was established in 2002 and established comprehensive flood prevention measures. In 2003, the National Disaster Management System Planning Group was launched, and the relevant ministries and experts from academia and business sectors participated in developing a comprehensive plan for effective disaster risk management.

Major Policy Change

The major policy changes made after Typhoon Rusa and Typhoon Maemi and the Daegu subway fire were the enactment and revision of the Disaster Management Act and the strengthening of the emergency response organization. After Typhoon Rusa, in September 2002, the Natural Disaster Countermeasures Act was amended to create a “special disaster area.” In 2004, the Framework Act on the Management of Disasters and Safety was enacted to integrate the Natural Disaster Countermeasures Act dealing with natural disasters and the Disaster Management Act dealing with human-caused disasters. In 2005, the Natural Disaster Countermeasures Act was completely revised by introducing new systems to improve the prevention and recovery of natural disasters dramatically. Significant institutional reform was the establishment of the National Emergency Management Agency (NEMA) in 2004. The NEMA was the first independent organization in charge of natural disasters, human-caused disasters, fire prevention, and civil defense (Fig. 2).

Public Need

The sinking of MV Sewol occurred on April 16, 2014, and 304 out of 476 passengers and crew died in the disaster. Among the 304, around 250 were students from Danwon High School in Ansan City. After the incident, 132,186 articles (as of

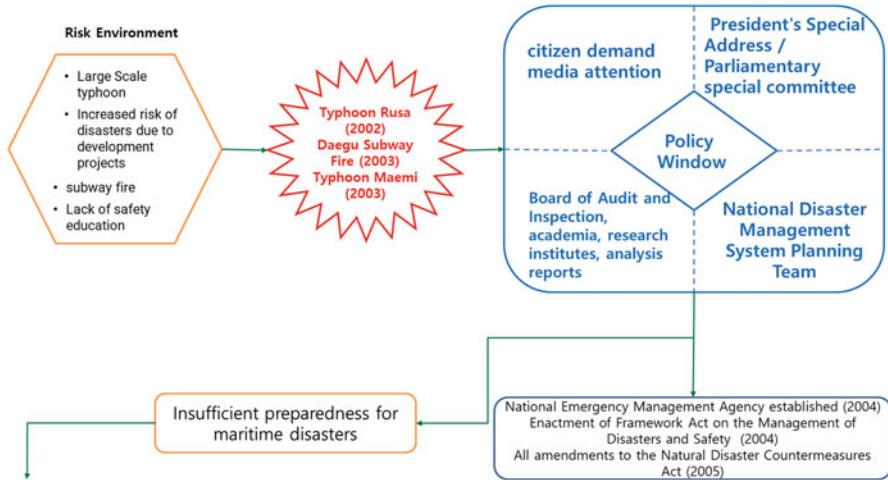

Fig. 2 Policy changer after Typhoon Rusa, Typhoon Maemi, and Daegu subway fire accident

2014) containing the keyword “Sewol” were reported, with more than 300,000 SNS records. After the media reported the sinking, the media reported in detail the cause of the accident, the rescue situation, and the current state of damage, and the public’s attention was focused.

Problem Identification

Several organizations, including the Board of Audit and Inspection, investigated and analyzed the cause of the Sewol ferry sinking. The ship’s resilience was weakened at the time of operation due to an unreasonable expansion and remodeling. Also, on the day of the accident, there was a problem in restoring the balance of the ship because it was loaded with about twice the maximum cargo capacity and did not comply with ballast regulations. The crew renounced their duty to save the lives of passengers without a proper initial response. In addition, systemic problems were also identified. As regulations on vessel operations were eased several times, vessel safety inspection standards were weakened, and the Enforcement Decree of the Seafarers Act allowed the captain to act on behalf of others so that an inexperienced navigator at the time of the accident was in charge of the operation. In addition, the Coast Guard’s poor initial response and shortage of diving rescue personnel were also revealed.

Political Leadership

On May 19, 2014, President Park announced a public discourse related to the Sewol ferry disaster. At this time, the President made an official apology, announcing the dissolution of the Coast Guard, and announcing that the maritime rescue and

maritime security sectors would be transferred to a newly established ministry. The National Assembly formed a special committee to investigate the sinking of the Sewol and worked hard to find out the truth of the tragedy, to support divers and to boost morale, to prepare measures to support victims' families, and to enact a special law for the Sewol ferry.

Administrative Effort

At around 9:10 a.m. on the day of the accident, the Korea Coast Guard activated the rescue headquarters, and the Ministry of Oceans and Fisheries formed the Central Disaster Management Headquarters to deal with the accident. And around 9:45 a.m., the Central Disaster and Safety Countermeasures Headquarters was in operation. On April 20, 2014, the Prime Minister held a meeting of relevant ministers and decided to declare Ansan City, where Danwon High School is located, and Jindo County, where the accident occurred, as special disaster zones, and the agenda was immediately approved by the President. At the meeting of the Central Disaster and Safety Countermeasures Headquarters held on April 23, the government first provided financial and state support for physical and mental treatment expenses for the injured, Danwon High School students, faculty, and rescue workers who did not board the Sewol ferry. For the cost, it was decided to exercise the right to indemnity against the Chonghaejin Shipping Company and others. And recognizing the problem that private diving rescuers who went to search for victims were not being paid wages and were working for a long time in a dangerous environment, on June 17, 2014, the government prepared a payment plan to pay them immediately.

Major Policy Change

As the amended Government Organization Act came into force on November 19, 2014, the Ministry of Public Safety and Security, a ministerial-level ministry directly under the Prime Minister, was newly established to take charge of the national disaster and safety management. The Korea Coast Guard and National Emergency Management Agency was renamed to the Maritime Police Safety Headquarters and the Central Fire Department, respectively, and belonged to the Ministry of Public Safety and Security. The Ministry of Safety and Public Administration, which had been in charge of the overall disaster and safety functions, was reorganized into the Ministry of Government Administration and Home Affairs in order to take charge of local autonomy, government organization management, and other administrative affairs. In addition, the Special Act for Investigation of the Facts of the April 16 Sewol Ferry Disaster and Construction of a Safe Society, etc. (Law No. 12843) containing information on the formation and operation of a fact-finding committee for the investigation into the truth of the Sewol ferry disaster was enacted on November 19, 2014. On January 28, 2015, the Special Act for Relief and Support for Damages from the 4·16 Sewol Ferry Disaster (Act No. 13115) was enacted. And

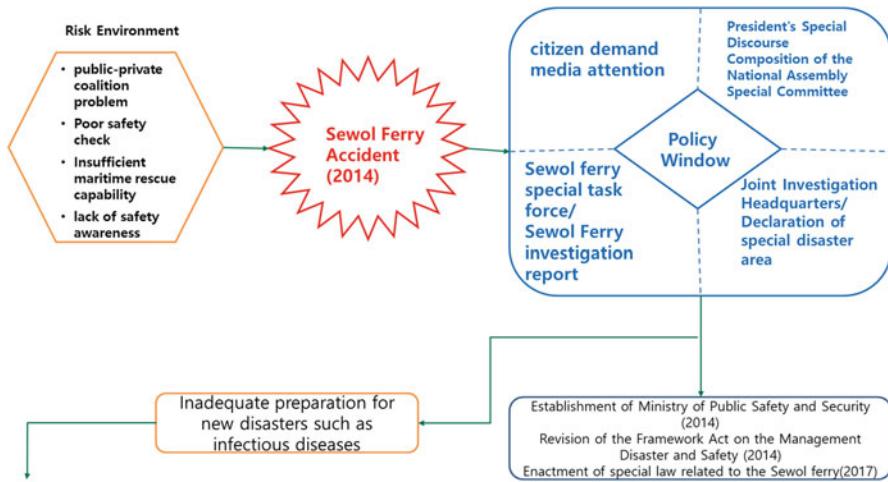

Fig. 3 Policy changer after Sewol ferry accident

on March 21, 2017, the Special Act on the Establishment and Operation of the Sewol Ferry Hull Investigation Committee (Act No. 14734) was enacted, which stipulates matters related to the hull investigation after the Sewol ferry salvage (Fig. 3).

Public Need

On August 29, 2005, Hurricane Katrina struck the southeastern United States. Louisiana's governor declared a state of emergency for the state before the hurricane landed, and asked President Bush to declare a federal state of emergency. This has enabled FEMA to organize and mobilize resources to help New Orleans residents. The Mayor of New Orleans issued a voluntary evacuation order on August 28, and the Superdome was opened for residents who could not leave. After the direct hit of the hurricane, FEMA mobilized 1000 Homeland Security officials to provide assistance to the city. Despite these efforts, devastating damage including a total of 1836 fatalities and \$125 billion damage occurred. According to Birkland (2006), on November 10, 2005, a search for legislation containing the word "Katrina" in the Thomas database of the Library of Congress found that 48% of 293 items billed with Hurricane Katrina in the title. Also, 24% had the word "relief" in the title, and 9% and 5% mentioned "recovery" and "reconstruction" in the title, respectively. The word "preparedness" appeared in three bills (1%). However, the word "mitigation" did not appear in any legislation. Birkland (2006) pointed out that the absence of any mention of mitigation or preparedness meant that 2 months after the disaster, it was not a major concern of Parliament. It was one of the largest hurricanes in US history and attracted worldwide attention. At that time, the US media focused on official announcements, such as reporting the scale of the victims and the criticism of politicians in the affected area for the delayed relief activities.

Problem Identification

After the 9/11 terrorist attacks in 2001, policy attention and budgets were concentrated in the area of homeland security, and preparations for natural disasters were neglected. FEMA focused on relief after the damage occurred, and its expertise and role in risk reduction and disaster response were weakened. Based on this awareness of the problem, the US Senate Committee on Homeland Security and Governmental Affairs prepared the Hurricane Katrina Investigation Report. In this report, what the government did well and what it did wrong was identified, and it was recommended to reorganize the national disaster management system to respond quickly and effectively in the event of a similar disaster. Specifically, it was to create an organization with full authority to take charge of disaster preparedness and response and to empower local and state governments to respond. The problems pointed out in the US Senate's 2006 report (*Hurricane Katrina: A Nation Still Unprepared*) are as follows. First, all government-level roles that had to plan and prepare for the ripple effect caused by Katrina failed. Second, it failed to draw attention to the growing large-scale disasters before the hurricane strikes, and it also failed to predict the landing date. Third, the government leadership failed to comprehensively consider the various response factors before the hurricane attack and did not recognize the problems of the existing response plan when faced with the worst-case scenario. Fourth, government agencies at all levels failed to formulate a plan to evacuate the elderly, sick, and disabled people in New Orleans in a timely and effective manner and failed to secure the means for evacuation. In addition, it failed to evacuate many citizens who did not have personal means of transportation. Fifth, the government has not acted on the lessons from the large-scale disasters of the past. It did not recognize that large-scale, well-equipped, and coordinated efforts to maintain order and repair damage were essential after catastrophic human-caused or natural disasters have occurred. Finally, the government failed to provide adequate medical assistance and temporary shelter in a timely manner for the numerous victims of large-scale hurricanes.

Political Leadership

At the time, while on vacation in Texas, President Bush looked around the scene through the window of his presidential airplane, receiving public criticism for doing so. President Bush was late to the scene and publicly praised Michael Brown, the director of FEMA, for being very proactive to respond to emergency. However, Brown failed to accurately grasp the situation and failed to respond appropriately, so he was fired 10 days after the incident. President Bush's approval rating plummeted to 30%, and his image changed from "strong leadership" to "incompetence."

President Bush recognized that the government's initial response to the disaster had failed. Therefore, he went on TV to apologize for the government's failure to

respond to the disaster and his actions. In 2006, the US Senate submitted a report on Hurricane Katrina: a nation still unprepared: special report of the Committee on Homeland Security and Governmental Affairs, which presented problems in the response process to Katrina and recommendations based on it.

Administrative Effort

The United States prepared a report containing 17 lessons learned and 125 recommendations and started work to prevent a recurrence and put it into practice through the Post-Katrina Emergency Management Reform Act of 2006. The Act authorizes FEMA to coordinate and support the federal government's disaster prevention, preparedness, response, and recovery activities. In addition, FEMA was given the authority to perform disaster management tasks, such as supporting transportation facilities in the event of a major disaster and identifying the unmet needs of victims. As such, FEMA has been given new authority for disaster management and has been able to bridge the gap for effective disaster response. The National Response Framework (NRF) has replaced the National Response Plan. The NRF aimed to improve consultation between state and local governments and to provide flexibility in disaster response. A "whole community" approach was taken in which all participants in the community can work together. The framework included new partners such as public health institutions, logistics, and supply chain management.

Major Policy Change

The Post-Katrina Emergency Management Reform Act defined the Federal Disaster Management Agency as a disaster response-focused agency that leads national efforts to prepare for or protect against natural, terrorist, and manufactured disasters. As a result, the status of the Federal Disaster Management Agency, which had been weakened under the Department of Homeland Security, was elevated, and the agency's independence was recognized to a substantial extent. In addition, the National Disaster Management Center was installed to unify disaster countermeasures, and a separate search and rescue team, the Urban Disaster Search and Rescue (US&R) Task Force, was also established and operated. In addition, the procedure was simplified so that direct federal intervention could be carried out quickly without intermediate processes, and disaster preparedness functions were strengthened to minimize damage in the event of an accident. In particular, the extent of private participation in the National Response Plan (NRP) has increased. From the planning stage, the scope of private participation was set in detail, and it was made so that it could be used at any time. For example, a large discount store near the disaster site is set in advance, and drinking water and food are automatically supplied immediately (Fig. 4).

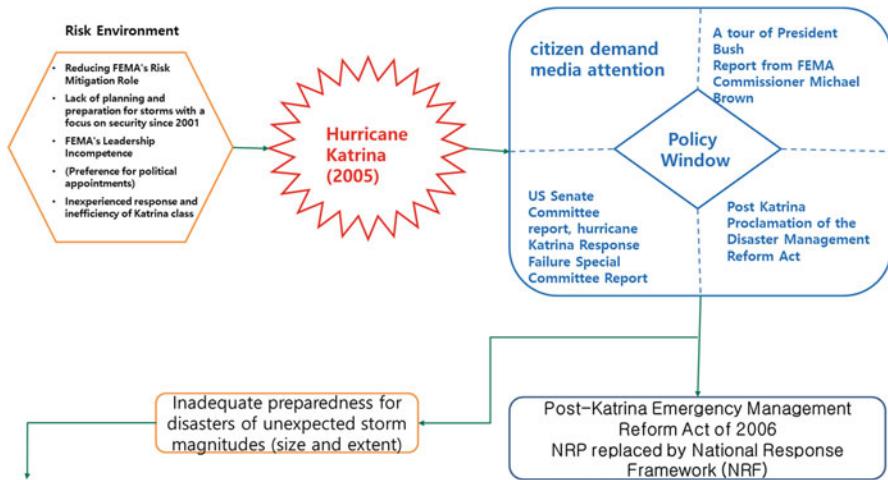

Fig. 4 Policy changer after Hurricane Katrina

Policy Implications

Understanding the process of policy change for disaster response after a major disaster that caused many deaths and massive property damage is essential to achieving a resilient society. By applying the PCAD model to cases in the United States and Korea, the authors were able to understand that disaster-related laws and emergency management organizations change along the path of various factors after a large-scale disaster, which can be considered a focusing event, occurs. In general, a catastrophic event will be followed by four main streams: citizens' interest and demand for institutional reform, problem identification, political leadership, and administrative effort. As these streams flow and interact with each other, policy changes occur as the policy window opens. Catastrophic events do not necessarily entail changes in disaster response organizations and laws. When citizens, governments, politicians, and the media, who have been greatly impacted by large-scale damage, pursue change with a strong will, the disaster response organization and laws can be improved. In Korea, after Typhoon Rusa in 2002, Typhoon Maemi in 2003, and the Daegu subway fire in 2003, the National Emergency Management Agency, the first independent disaster management agency, was established as a deputy minister-level organization, and the Basic Act on Disaster and Safety Management was enacted to integrate the management of natural disaster and human-caused disaster. And the Sewol ferry sinking incident in 2014 corresponded to the establishment of the Ministry of Public Safety and Security, the first ministerial-level disaster management organization. In the United States, significant functional reinforcement of the FEMA was achieved after the enormous impact caused by Hurricane Katrina in 2005, and the Post-Katrina Emergency Management Reform Act was enacted in 2006. These policy changes are typical examples of the PCAD model.

It is crucial to understand the content and direction of policy changes that occur after a large-scale disaster. Policy changes after a large-scale disaster should aim to establish a national disaster response system that can sufficiently respond to risks that can cause huge damage. Recent studies show that large-scale disasters that are considered extreme because of their low frequency are no longer extreme. In modern society, large-scale catastrophes with great social impact can occur at any time. Therefore, policy changes made after a disaster should aim to establish a disaster response system that thoroughly prepares for unpredictable large-scale disasters, on the premise that they can occur at any time. First, safety inspections and diagnosis of high-risk facilities such as old industrial complexes should be thoroughly conducted to reduce the probability of large-scale accidents. It is also important to increase the government's initial response capacity so that an accident does not develop into a national crisis. Regular training should be strengthened so that an exact situational awareness, prompt reporting, and appropriate measures by first responders can be made. Lastly, it is necessary to develop a response scenario for a national crisis that may occur and establish a system in which all relevant organizations can form a cooperative network to respond effectively.

Policy changes should be made in the direction of integrated management of all types of disasters according to the principle of comprehensiveness. An effective response to a national crisis requires strong leadership and authority to coordinate and control all ministries and local governments. The role of an overall coordination institution is essential in facilitating all actors, such as the central government, local governments, and civic groups, to participate in the entire process of the disaster management cycle and uniting the disaster management capabilities of all actors as a unity of effort. FEMA and DHS in the United States and NEMA and MPSS in Korea are representative examples of the overall coordination institution for disaster risk management. The important tasks of these coordination institutions include minimizing damage by efficiently mobilizing all resources according to the principles of standardization and flexibility by on-site response agencies, local governments, and line ministries to support the victims, restore damaged facilities, and provide disaster relief when a disaster occurs. To perform these tasks, the coordination agency must have the authority to comprehensively coordinate disaster responses among line ministries, local governments, and public institutions for all types of disasters, and trained officials to make prompt decisions under crisis.

Establishing risk governance in which all members of society participate which is essential to realizing a resilient society. Risk governance should be established to strengthen accountability in all sectors and strengthen cooperation among stakeholders. Reinforcing disaster response agencies and laws alone is not sufficient to cope with disasters in modern society, which are becoming increasingly complex and intensifying. Establishing risk governance that ensures the participation of all stakeholders is an essential element for establishing resilience at all levels of society. Such a system should be established based on the basic principles of governance such as responsibility, participation, norms, efficiency, and sustainability and should be established through disaster risk management systems and policies.

Conclusion

In this study, the Policy Change After Disaster (PCAD) model was proposed to explain the factors that induce policy change, such as institutional reform and legal reinforcement, after a disaster. The PCAD model was designed by adopting key elements of previous models, such as Kingdon's PSF (Policy Stream Framework) model, Birkland's ERPL (Event-Related Policy Learning) model, and Kim's DTPC (Disaster-Triggered Policy Change) model. The authors applied the PCAD model to investigate the five cases of policy change: the establishment of the NEMA in 2004 in Korea, the enactment of the Basic Act on Disaster and Safety Management in 2004 in Korea, the establishment of the MPSS in 2014 in Korea, the strengthening of the FEMA in the United States in 2006, and the enactment of the Post-Katrina Emergency Management Reform Act in 2006 in the United States.

The policy implications of the analysis are as follows. First, policy change after disasters is likely to happen by the interaction of the following four streams: citizens' interest and demand for institutional reform, problem identification, political leadership, and administrative effort. Second, large-scale disasters do not necessarily entail changes in disaster response organizations and laws. The authors found that disaster response organizations and laws can be improved only when the citizens, governments, politicians, and the media pursue change with a strong will. Third, in general, policy changes cannot solve all the problems embedded in the society, implying that vulnerability remains and that a catastrophic event can occur when certain conditions are met. Therefore, all actors, such as the central government, local governments, and civic groups, should monitor vulnerable factors continuously and strengthen activities to increase the resilience of society. Finally, the government should prioritize enhancing the national disaster response system so that it can appropriately respond to all types of risks. Responding effectively to national crises requires a central coordination institution having strong leadership and authority to coordinate and control all ministries and local governments. In addition, it is crucial for the coordination agency to have political leadership that makes it possible for all actors such as the central government, local governments, and civic groups to participate in the entire disaster management cycle. Policy changes after a large-scale disaster should be conducted in the direction of integrated management of all types of disasters.

Abstract

The idea of smart cities emerged from a global concern for capacity enhancement of existing cities and their quest for sustainability of resource use for the rising urban population. The demand for essential services has been going beyond the carrying capacity of city’s available infrastructural ability to deliver. Urban areas bear disproportionate load of providing electricity, water, banking, housing, health, food, transport, and other support systems. Any scarcity or nonavailability of these resources increases vulnerability of citizens to varieties of disasters. While resilience building against disruptions of basic supplies remains the central objective of smart cities, there is no denying the fact that smart cities create technology determined spaces, which overlook inclusivity, justice, and equity. The management of enormous flow of data is expected to enable city managers to plan, provide, and adapt to contingencies of modern urban lives but it does not at any point indicate that the critical infrastructure would prioritize these democratic principles over which sustainability is built. This culminates into unreliable and uncommitted disaster preparedness with high possibility of divisive and

exclusionary tendencies such as racism, speciesism, casteism, and prejudiced sexual orientations within which takes place an exclusion of poor, disabled, women, and weaker species who have no resources to control technology. Three questions become pertinent for any researcher on disaster management: first, what is the connect of smart city concept with disaster management? Second, is there greater resilience against disasters in a smart city? Third, which cities would be “smart enough” for disaster prevention?

Critical infrastructure · Resilience · Contingencies · Speciesism

Introduction: Understanding “Smart,” “Unsmart,” or “Smart Enough” Cities (The Connect with Disaster Management)

To understand “Smart,” ‘Unsmart,’ or “Smart Enough” Cities is not a difficult exercise under traditional archetype of urban habitats. To begin with an oft-quoted description of an “Unsmart” city, one visualizes a city full of traffic congestion, garbage, water shortage, illegal constructions, shrinking green areas, corruption with impunity and crime. In sharp contrast, a “Smart” city is presumed to have overcome all these problems of an unsmart city, is clean, responsive, safe, and has respect for the rule of law. One can see that the contrasting factor between the two is that of “institutional functioning” alone due to which the city’s preparedness turns into its smartness. It is due to some smart institutions that much of good disaster management is expected to come naturally in a smart city not through technology alone.

The much publicized contemporary concept of a smart city can be understood through its differentiation from the traditional concept. How the three main drivers of change are located within the two may reveal their real nature. These three drivers are, i.e.; government, citizens, and corporates. Modern smart cities differ from the traditional ones in that the push for reform in the former comes from corporates and in the latter from citizens’ organized campaigns and protests against government inaction, apathy, and negligence. Ironically, standards and indicators for smart city ranking are picked up not by governance experts who would have rated “institutional functioning” as the key indicator but ranking has become a sole prerogative of the “Corporates” or “business investors.” Some of the key corporates that have been creating ranking systems for “Smart” cities are the IMD-SUTD Smart City Index, AT Kearney Global Cities Index, Mori-Foundation Global Power City Index (GPCI), and SECI Index by Smart Eco City Ltd., and top Corporates designing “Smart” cities are CISCO, PWC, Siemens, IBM, KPMG, and their few peers controlling this exercise from the top. So, a smart city today is what tech corporates want it to look like. Nowhere does one find any mention of a trajectory of a growing smartness of an “Unsmart” city as cities picked up to clothe in smartness are the cities which are already “Smart enough.”

If there is a smart city then there definitely would exist an “Unsmart” city too. Have the corporates reached out to “Unsmart” cities, which reflect inertia to any change and has any effort been made to transform them to “Smart” cities? One would gradually come to an understanding that cities are “Smart” or “Unsmart” due to their “institutions” and their “citizens” and not due to corporates, and therefore high HDI ranking cities were “Smart enough” for providing resilience and human security. So, is “Smart” a tech-implantation in a complete absence of any discourse on “institutional reforms”? Should the locus standi of the Ministry of Urban Affairs where “Smart City Mission” is located be questioned and shouldn’t DARPG (Department of Administrative Reforms & Public Grievances), which works on administrative and institutional reforms, stand up to reclaim its authority over this corporate mission?

As mentioned earlier, traditionally, cities were considered smart for their institutional outreach, simplicity of laws, and participatory governance. They were rarely “absolutely smart” but mostly “smart enough” to be inclusive and equitable as they collectively moved to reform institutional gaps. On the other hand, the new found “smart city” is smart because it applies many newfound smart technologies from the tech world of nanotechnology, Artificial Intelligence (AI), Cloud Computing, Machine Learning(ML), Internet of Things (IoT), Robotics, and Big Data analytics. This system is rooted into a virtual World Wide Web that stores information, conversations, decisions, and notifications on websites presuming that people are smart enough to access and afford them all whenever needed but ignorance of e-information is not pardonable for citizens in automated smart technology. A natural concomitant to this situation is that governments are no more duty bound to reach out to everyone as long as they are uploading all information in time on public websites. It is presumed that internet-based public information is reaching everyone. The premise of governance changes in a smart city. Therefore, while governments achieve greater capacity for focused and targeted action during accidents, calamities, and disasters as forecasting capacity of early warning systems increase and speedier solutions are obtainable, it nevertheless, brings benefits to only those with internet connectivity. So far smart cities demonstrate no innovative wisdom in taking everyone together as is traditionally understood for generating city’s social capital for inclusive governance. The much-hyped technological innovation of “smart cities” remains a corporate fiction or a “glib phrase” (The Advertiser (1996) ‘A Grand but Last Hurrah’, Adelaide, Oct. 29) as remarked by a newspaper in Adelaide calling it a “spin doctor’s latest wheeze” or a politically motivated sweetened phrase to please people.

In the September 2010, the New York Summit meeting between Bill Clinton and the service spirited Chairman of Cisco Board, John Chambers initiated the idea of Smart Cities. The global technology leaders agreed to bring a technology for change and development. The concern to make cities sustainable through digitization and to utilize digital networks for making cities more resilient to turbulence, accidents, and disasters in highly populated densities of urbanizing world technology of IoT and AI came as practical solutions. Following this meeting, a \$25 million project was launched in 2010. One could witness the returns to IT companies in selling

technology for Smart City projects. Cisco alone grew from \$70 million in the mid-nineties to \$1.2 billion and then an astounding jump to \$47 billion within 5 years. The global market for smart cities (Global Smart Cities Market Report (2022)) stood at USD 1226.9 billion in 2022 and with a compound annual growth rate (CAGR) of 25.8% from 2023 to 2030 (Market Analysis Report 2023–2030) the market is likely to reach USD 2.8 Trillion by 2027 (Smart cities: Global Strategic Business Report (2023)).

Francis Pisani in his book *A Journey through Smart Cities: Between Datapolis and Participopolis* (2015) calls it a gold rush for information technology market as data managers and tech experts outshine the participatory trends of city democracy. In India where the Smart City Mission started in June 2015 with around 100 smart cities to be built by 2020 now seems to extend much further. In the neighborhood Sri Lanka and Bangladesh, digital transformation is leading to Smart City initiatives such as connecting 2500 schools for smart education as in the former and for developing ultramodern power grids, green economy, and skills in a merit-based economy of the latter. European Smart Cities aim to improve quality of life for their citizens and achieve energy and climate targets. There is a world of difference between models of Smart Cities in South Asian region and that in the developed countries of North America and Europe. Whereas, smartness is to be achieved in South Asia from an “Un-Smart” urban area, North America and Europe are starting from an inherently smart environment of high HDI, advanced infrastructure, and a skilled digital economy. Nonetheless, there is greater fear of losing indigenous skills and social capital as governance is deflected from citizens to corporates in developing countries due to fast-track implantation of Smart Cities. The big question mark remains whether these nebulous technology models could bring smart-disaster management as well. In a recent disaster (ABP Live, 30th March 2023) at Indore in India, which is India’s no.1 ranked Smart City, the much delayed and deficient response of government’s rapid action force, emergency equipment, and medical support demonstrated unsmart disaster management. This suggests that even if Smart Cities have phenomenal databases and digitization, delivery to the last mile requires human effort or as Yeafesh Osman, the Science and Technology Minister of Bangladesh, appropriately sums up as possible “only if hardware, software and human-ware simultaneously integrate each other” (Prothom Alo English Desk (2022)).

Is There Greater Resilience Against Disasters in Smart Cities?

Smart Cities are considered smart due to their smart technology. For example, a fast response to disasters as a bare minimum is what ought to be expected of expensive smart technology installed in a Smart City. When IBM was working on the Smart City of Rio de Janeiro (Halegoua, 2020, p. 253) in 2012, three adjacent buildings collapsed in the city’s downtown area but the speed and manner in which ambulances, rescue teams, evacuators, shut down of gas stations and power and subway stations was achieved and then social media platform used to secure vicinity for movement of rescue operations came down as one of the best spectacle of “Smart-

ness” expected of a city. A model of staying prepared irrespective of human frailties is a design being promoted by top tech ICT companies for “smart-ness.” However, for technology too there are limitations to its autonomy. One can identify four conditions being primordial to its optimum performance and resilience building:

1. City’s decision-making system should be smart (or SMART which is a mnemonic acronym suggesting five traits of good project management), i.e., specific (simple and sensible), measurable, achievable, relevant, and time-bound. It requires educated, trained, responsible, and sensitive administrative system, which is accountable and performance oriented. There should be a separate and independent supervisory team to be watchful of performance evaluation and rating. The base of Smart City is embedded within institutional governance and not technology alone. An administrative system that governs the city such as the District Magistrate, Town and Country Planner, Municipal Commissioner, and Police Chief is the key to “Smart” cities.
2. Availability of City “Sensors” (ICT and human) to be able to provide real-time data, which could be swiftly understood, interpreted, and applied to take decisions during adverse conditions. This may not be a simple task as here arises an obvious need for “Metadata,” which is an outcome of a huge amount of data obtained from heterogenous sources of critical infrastructures of smart cities. Metadata synchronizes, authenticates, and integrates large volumes of data (Big Data and AI) to provide a holistic visual of a disaster (Sun et al., 2020). This could be connected to the Cloud or IoT to be freely available whenever needed.
3. Autonomy of information dissemination without human trespass need to be assured. The ICT System should be able to provide real-time data independently and autonomously so that even a freak incident is responded to without waiting for humans to understand, plan, and execute. Social media sites like Twitter, Facebook, and IoT can be great transmitting platforms for real-time data. Global Forest Watch (GFW) is an initiative of the World Resources Institute with an open source web application to monitor global forests and provide free real-time data for managing forest fires and other concerns.
4. Data visualization is a stupendous achievement of AI and 3-D Google Earth visuals. When Geo Spatial data (Sud, 2020) and Remote Sensing is combined with the experience and history made available in the databases, disaster management authorities may become better placed to visualize many disasters such as floods, landslides, fire, etc., in early event detection. High Resolution Satellite Imagery like the Cartosat One and Ikonos for a multisectoral and panchromatic imagery used to detect minor forest fires through its high detection capacity could also be used in high density, vulnerable city areas to enhance capacities of fire personnel. This capacity to visualize brings cost-effectiveness, better quantification besides saving lives by generating ability for prediction and reducing cascading damages.

Many authors (Ford & Wolf Charles, 2020) reflect upon the technology–community relationship in smart cities as brought out in the above points. He describes Smart cities as “ICT using communities which autonomously sense, store,

and make current information on community conditions that is easily available to community leaders and citizen's." However, to ensure availability and accessibility of information to community leaders and citizens, Smart Technology can only work in a society where citizens are laced with appropriate training, education, and also softwares for a sophisticated control over technology.

Which Cities Would Be "Smart Enough" for Disaster Prevention?

It is presumed that "Smart" cities provide faster response to disasters nonetheless being by-products of neoliberal economy (Greenfield, 2013; Grossi & Pianezzi, 2017). They may discount equity and inclusive approach in their response. Raised upon cost-effectiveness and efficiency as beacon lights, exclusion may come inadvertently. Picking up from the legendary literature of Adam Greenfield these "Smart" cities are different from their forebears, which were sprawling areas extending toward hinterlands and gradually achieving smartness through administrative reforms embedded in Rule of law. Notwithstanding the fact that Smart cities were built through convergence of innumerable segregated projects, dedicated apps and interdependent infrastructure networks (Sun et al., 2021), capacity for disaster prevention ultimately relied heavily on available databases. How smart could these cities be in handling disasters depends on sophisticated integration of databases and human decision makers (Elvas et al., 2021).

Another requirement of smartness was availability of Early Warning Systems as part of technology network in a city. A quick survey of Early Warning Systems in some important world cities aspiring to become smart reveals many challenges and limitations of applied technology;

Dubai as everyone knows is smart enough to manage a very high footfall of foreigners. The Dubai Municipality with its emergency management system connected to Public Health and Safety Department ensures resilience building for making cities disaster proof. There are Special Task Forces for attending to Emergency Planning to prevent flooding of roads in rains, fire, and zoonotic and communicable diseases. Dubai Police coordinates many segregated departments such as Civil Defense health, transport, Electric and Water Authority, and Dubai Municipality for early response. Yet, this depends upon a committed and consistently supervised coordinated planning, mapping, regular public preparedness drills, and technology monitoring to bring out best results.

Israel's Jerusalem and Tel Aviv have advanced EWS systems. Nanometrics, a Canadian company which has installed EWS on earthquakes gives 10–30 s alert between the epicenter's first wave and the terminal wave that causes destructiveness. Another, Ottawa-based company, along with its partner Motorola Israel, has set up monitoring stations in the Dead Sea valley, the Jordan Valley, and the Haifa area, which are the earthquake zones. The command and control centers relay emergency alerts for people automatically. Interestingly, many smart enough cities in Israel used a simple gas balloon (Grossman, 2023) for a perfect evacuation plan rather than expensive technology-based EWS.

Technology in **Indian** cities is transforming organizations responsible for forecasting and issuing weather alerts such as the Indian Meteorological Department (IMD). It initially started with a two-stage alert system but is now issuing alerts in many stages from the “Pre- Cyclone watch” to the “post-landfall situation.” Addition of more stages in sending alerts and warnings has enabled crisis managers and district administration to make an early detection with enough time in hand to evacuate people to safer places. With the coming of smart technology, advancement has been fast toward Aircraft Meteorological Data Relay system, the Cloud Motion Vectors (CMVs), and the Very High Resolution Radiometer (VHRR) payload onboard INSAT –2E. This has been able to provide water vapor channel data, which is an important factor in monitoring climate change and weather systems. The remote sensing data obtained from earth observatory satellites alongside VIS and IR (visible and infrared imagery) strengthens early warning capacities of organizations, which in current discussion is the IMD. However, states with functionally responsible governance have utilized advanced technology for disaster management such as Odisha but states where negligence, apathy, corruption, and political influences disturb decision making such as Kerala (2018 floods in Singh et al., 2018) and Uttarakhand (Kedarnath glacial lake outburst 2013, Chamoli 2021 Glacial landslide disaster in Upadhyay, 2022) “Unsmart” cities sometimes continue to survive behind a tourist friendly welcome look of smart shopping and heritage conservation but when disaster strikes the real picture surfaces. Indore (Choukse, 2023), the no. 1 ranked smart city in India has recently been exposed for a temple disaster but more than that is the exposure of inactive administration, which repeatedly failed to act against illegal constructions in defiance of city’s building bylaws.

The case studies discussed in earlier paragraphs are picked up from “smart enough” cities and have highlighted certain requirements for achieving sustainability in a tech-centric “Smart” city discourse. Cities which are “smart enough” for disaster prevention could inculcate and engender the following indispensable requirements brought together from case studies across many “smart enough” cities”:

1. Respect for the “Rule of Law” and accountable administration.
2. Advocacy and Civic engagement as part of participatory governance.
3. Functional economy with appropriate logistics, market measurement, consistent job growth, and opportunities in the job market.
4. Absolute functionality, maintenance, and supervision of Smart city critical infrastructure especially toward its “early warning” capacity.
5. Feedback loops on accessibility to technology-based solutions and to decision making.

Conclusion

Cities are “Smart,” “Smart enough,” or “Unsmart” to begin with a discourse on what provides better disaster management. Smart cities are technology-driven and byproducts of neoliberal economy with cost-effectiveness and efficiency as their

beacon lights to being smart. This makes exclusion unavoidable in a perfectly modeled smart city. Three questions become pertinent for any researcher on disaster management, first, what is the connect of smart city concept with disaster management? Second, is there greater resilience against disasters in a smart city? Third, which cities would be “smart enough” for disaster prevention?

However, many cities are smart from the beginning and organically develop their critical infrastructure as needs arise. These, which the chapter refers to as “smart enough” cities also advance with administrative reforms, participatory governance, and rule of law that gradually makes them robustly smart. However, in contrast “unsmart” cities exist in large numbers but the controlling top Corporates have no indulgence in their development. Disaster management in some key cities has been discussed especially in the context of technology that provides sophisticated Early Warning Systems and it is concluded here that a “Smart city” is one which could balance technology with community needs, skills, training, and interests. Expensive technology implantation without responsible, trained, and accountable governance may not be capable enough to respond to disasters as smartly as suggested in smart city concept.

Abstract

Economic and social complications in addition to loss of many invaluable lives came with the COVID-19 pandemic. Amid the COVID-19 disaster, digital technologies and their applications became a powerful mitigating tool. Experience of several cities around the world indicates that smart city technologies enabled local and central governments as well as firms to provide various public and business services in a fast and effective way while complying with the social distancing, quarantines, and COVID-19 curfews. This chapter elaborates how the city-level adoption of digital technologies in Tehran, the most populous city in the West Asia, mitigated the pandemic impacts. Smartening initiative in Tehran commenced in 2015 and was accelerated by the COVID-19 spread. Contact trace, surveillance, telemedicine, and telework are among the key applications of smart city technological solutions in Tehran during the pandemic. This chapter categorizes these applications in different dimensions including mobility, environment, health, etc. In particular, MyTehran, a mobile application, which offers

public services and Corona+ program, supporting digital startups and firms working on relevant solutions to alleviate COVID-19 consequences, are notable instances of how smartening Tehran enhanced its resilience against the pandemic. Chapter's conclusion explains varied challenges that Tehran faces in the path of transition to a smart city prior to, throughout, and post-COVID-19 pandemic.

Keywords

COVID-19 · Smart city · Urban disaster · Smartening Tehran

Introduction

The rapid and prevalent spread of COVID-19 since late 2019 has impacted the world, and millions of people have been infected with the virus. In this situation, offering reliable data for citizens, disseminating health guidance, and preventing the occurrence and aggravation of economic problems are the main challenges of cities. The high rate of COVID-19 transmission has had broad social impacts, including restriction of crowd, social distancing, and quarantine, that the smart city having a significant impact on complying with such considerations (Jaiswal et al., 2020). The utilization of smart solutions and technologies, focusing on healthcare, quarantine management, and citizen relations, is a common activity in smart cities (World Economic Forum, 2020). The growth of cities and the increase of urban population have created problems including heavy traffic, waste management, pollution, car park space, etc. Smart city is an effort to make cities a better place to live, and its initial concept was to improve the performance of cities through ICT. The concept of smart city, of course, is not bound to ICT and includes various interactive and human aspects (Camero & Alba, 2019). The integration of systems and services to improve the efficiency and optimization of urban management is facilitated through the smart city technologies. Providing and receiving services in a smart city need less physical communication, which played an effective role in disease control and prevention during the COVID-19 pandemic (Yang & Chong, 2021).

Technology has transitioned a lot in day-to-day life. Until a few years ago, smart city managers and executives saw advanced technologies as a behind-the-scenes tool, not directly in the lives of citizens. With the expansion of smartphones, technology has now been directly penetrated into people's daily lives. Only through a smartphone, a citizen can access to up-to-date information on various topics from traffic transportation to health and safety services (McKinsey, 2018).

In addition to being the capital city, Tehran hosts government institutions, industrial centers, and economic markets, which made the response to these challenges more complicated. Additionally, issues such as air pollution, traffic, and declining urban revenues are other challenges for urban management. Smart city technologies contribute to city-wide sustainability transitions and the quality of life. Smartening Tehran seeks to transform the city into a dynamic environment in which interaction among entrepreneurs, citizens, and government institutions leads to

economic and social development (Farjood, 2019). While the Smart Tehran program was at its early phases, the COVID-19 outbreak challenged citizens and business owners. Providing online services, innovative Tehran program, and digital transformation in Tehran Municipality by offering online services led to the reduction of crowd and helped to mitigate COVID-19. Tehran residents widely adjusted to teleworking and e-learning as well as online good purchases and services. MyTehran integrated platform and applications such as Bike app made social distancing possible (Parastesh, 2021).

This chapter firstly describes the smart city and its dimensions. Then it explains the impact of smart technologies and their pertinent initiatives throughout the COVID-19 pandemic. The subsequent sections go into Tehran smart city efforts to manage and reduce the effects of COVID-19. Finally, the challenges and suggestions for smart-resilient Tehran, in the case of future disasters, are discussed.

Smart City Dimensions and Its Technological Applications

Technology, people, and government are key constituents of a smart city. Besides, smart city does not limit to installing ICT infrastructure, but its functions and features can be categorized into six dimensions (economy, transportation, governance, environment, citizens, and life) (Ismagilova et al., 2019) as explained in Table 1. These dimensions complement each other, and their alignment is quite necessary.

Smart technological solutions improve life quality and transition to sustainability. The smartening process includes various software and hardware dimensions. In addition, infrastructures such as social innovation, education, culture, knowledge-

Table 1 Dimensions of smart city. (Adapted from Ismagilova et al. (2019), Kirimtak et al. (2020), and Jiang et al. (2021))

Smart life: Life quality increases with the management of smart buildings, healthcare, and public safety. Interactive voice response to report citizens' safety problems and smart and low-cost healthcare is placed in this dimension

Smart citizens: Citizens interact with the smart city through crowdsourcing. It means they can share their innovative ideas. It is essential to educate citizens regarding the benefits and utilization of smart city services along with addressing their concerns

Smart economy: In the smart economy, ICT is widely used in various industries. The potential for economic growth in smart cities increases through e-commerce

Smart transportation: Managing traffic congestion is rather difficult in big cities. Smart transportation improves urban transportation by providing solutions such as Internet of vehicles, new routing algorithms and using data to control traffic

Smart governance: The open governance paradigm widely shapes ICT-based partnerships in cities. Elements like citizen-centered and crowdsourced deliberation consulting allow citizens to be providing the desired model of public services

Smart environment: In a smart environment, issues including air pollution, waste management, and green urban spaces are evaluated by ICT. Increasing urban population highlights the need to pay attention to resource infrastructure and pollution control for better urban management and increased quality of life

based economy, etc. are important in city smartening (Sharifi et al., 2021a). The combination of smart city systems, services, and technologies must be flexible to be providing a platform for creating innovation, economic development, and creating collaborative and interactive spaces (Albino et al., 2015).

Technology plays a pivotal role in preventing and controlling pandemics, including COVID-19. Smart cities collect and integrate data from different sources; this is very effective in controlling the spread of the virus, especially in large cities. Smart city projects, including smart community, smart government, smart healthcare, etc., have more influence in real-time data sharing, reducing face-to-face and close interactions, and optimal allocation of resources during the pandemic. Thus, improving infrastructure, raising awareness, and attracting citizens to participate in smart city projects are very important. Smart information includes information sharing on floating population and geographical location increasing disease control efficiency. In other words, dimensions of the smart city complement each other and form a whole which is called the smart city. As a matter of fact, smart city technologies help governments, communities, and hospitals to provide an effective response to COVID-19 in their specialized responsibilities (Yang & Chong, 2021).

The elements of smart cities can be classified into three levels. The first level is based on technology and consists of open data portals and sensors connected by high-speed social networks constantly monitoring variables of energy consumption, traffic flow, etc. and providing information to applicants. The second level is specific applications. At this level, application developers and technology providers turn raw data into alerts and insights. Smart city applications cover various fields, including security, mobility, healthcare, energy, waste, and community participation. The third level is general use. Most programs succeed and lead to behavior change if they are accepted (McKinsey, 2018). Another key technological application of the smart city is enhancing access to education on the Internet by digital technologies. Digital technologies have revolutionized the way of education. Today, almost all top universities offer easy to access online courses in a variety of fields (Deloitte, 2015).

Applications of Smart City Technologies Throughout the COVID-19 Pandemic

An occurrence of unpredictable crises increases the uncertainty and vulnerability of cities. To improve resilience of cities, technology and digital tools play a key role. The three main components of a smart city are technology, people, and institutions. In the COVID-19 crisis, cities are known as the focus of disease, because of their high population density and mobility frequency. The prevalence of COVID-19 accelerated the digital transformation of cities, changed the behavior of citizens, and also redefined lifestyle. By utilizing the capacity of social media, smart cities are involved in informing citizens, and by providing big data, they help urban managers to make better decisions. The ability to trace and monitor people based on artificial intelligence and big data and digitalization of services to reduce unnecessary movement are among the measures that are taken by smart city. Generally, COVID-19

affects various aspects of life, and technology-enabled smart city solutions play a facilitating and effective role in areas, including healthcare, business, and education (Hassankhani et al., 2021; BCG, 2020).

During the COVID-19 pandemic, the role of ICT in our lives became more prominent than ever before. Thanks to information and communications technology, it is possible to support and maintain the supply chain and distribution network of essential items such as food, medicine, health equipment, etc. Information and communications technology is a public health information dissemination channel as well as a platform for the development of integrated policy guidelines. Moreover, ICT is the basis for developing platforms and programs for tracking, testing, and treating COVID-19 in various cities around the world (ITU, 2020a).

Improving citizens' knowledge and awareness regarding the COVID-19 is achieved by accessing valid and official information. Governments are responsible for providing updated information for citizens and the international community by medical organizations as well as control and informatics centers (Gultom et al., 2020).

The need for the Internet as an important tool for connecting and accessing infrastructure and resources has been challenging for governments across the world during this time. For example, high-speed Internet is an essential tool for hospitals and medical institutions so they could be accessing the global information network and resources needed to combat the disease. Access to broadband connection is also crucial for continuing educational institutional activities and business services. In fact, the COVID-19 pandemic has created the need for new action to achieve meaningful connectivity and key digital services (including education, health, financial services, etc.) in the community.

Over the pandemic, many governments, including China, Russia, the Republic of Korea, and the United Kingdom, used artificial intelligence to monitor the quarantine and track the virus. Smart governance technologies proved effective in rapidly identifying infected citizens, controlling and surveillance, keeping social distance and quarantine, as well as strengthening urban resilience in disasters (Sharifi & Khavarian-Garmsir, 2020). In India, 50 cities have ICCC (Integrated Command and Control Center) or COVID-19 war room (World Economic Forum, 2020).

Smart city technologies including telemedicine provide access to medical services and experts through telecommunications systems in all stages of the disease from hospitalization to treatment (ITU, 2020b). Besides, smart city technologies are considered as a preventive measure by regulating public transportation. Many efforts have been made to reduce the spread of the disease in various cities, including disinfection of public transport with large numbers of passengers such as trains, subway wagons, buses, as well as public transportation stations (McKinsey, 2020). Smart city technologies turned out effective throughout the COVID-19 pandemic in regard to abiding social distancing. Compulsory use of masks (in some countries from the time of leaving home; in others in shops and on public transport or in closed and crowded places) and avoiding crowds are some instances in this regard (McKinsey, 2020).

Smart City Technologies' Application in the World to Mitigate COVID-19

Amid the outbreak of COVID-19, almost all big cities faced new challenges and problems. The recent pandemic has affected all aspects of human life. Therefore, dealing with it needs special facilities and arrangements. Finding timely and efficient response in addition to capacity building and reinforcement of the infrastructure were of high importance for city authorities due to two key purpose – i.e., mitigating the disease through tracking and monitoring individuals and providing online services to citizens. Furthermore, the necessity of coordination between different institutions; integration of policies and decisions; human resources issues regarding new training, privacy, and data security; and, finally, citizen participation in the implementation of new guidelines and requirements are other challenges that officials are faced with. The applications of smart city technologies in the management and control of COVID-19 are explained in the following section.

Smart healthcare: Telemedicine (TM), the exchange of medical information through innovative technologies, received more attention during the COVID-19 pandemic than ever before. Patient-physician interactive visual sessions and healthcare-related instruction are realized in TM with a high-speed network and dedicated digital software. Utilizing TM, apart from saving time and reducing unnecessary movement, makes it possible to provide services to quarantined people with less access to medical facilities. Other benefits of TM include reducing the cost of healthcare and the risk of medical staff affliction while increasing patient satisfaction and efficiency of the healthcare system in the situation of offline doctor and patient interaction (Bahl et al., 2020). Telemedicine is developed based on IoMT technology and enables the transmission of patient information through wearable devices and chatbots and the possibility of monitoring and tracking them. Robots reduce the risk of the COVID-19 without the need to mobilize human resources (Chamola et al., 2020). Smart robots have been used in India, the United States, and Denmark to disinfect objects and public places. In China, autonomous vehicles were deployed to deliver food and medical equipment to hospitals. The Phone Pal program in the United Kingdom is a successful experience in maintaining social interaction and communication and avoiding isolation to improve community resilience (Sharifi et al., 2021b).

Contact tracing and monitoring: Tracking is one of the key actions of smart cities to control the pandemic. Tracking infected people by following their movement patterns leads to identifying people in contact with them and infected areas. Moreover, tracking facilitates effective monitoring of quarantine implementation (Sharifi et al., 2021b). Due to the high transfer rate of COVID-19, location-based technology solutions for crisis management have been considered. According to WHO, tracking includes three stages of contact identification, contact listing, and follow-up. Location-based technologies record and store citizen behavior from sensors and smartphone capabilities (Abbas & Michael, 2020). In Singapore, the TraceTogether program was developed to monitor and track people. The app detects infected people via cell phone Bluetooth and alerts those in contact with the infected

(Das & Zhang, 2021). South Korea, one of the successful countries in crisis management, undertook extensive diagnostic testing among citizens aged 20–30, who are often asymptomatic carriers of the COVID-19. Korea did the tracing by three mechanisms, i.e., credit and debit cards, CCTV cameras, and mobile phones. Time-space map data is then provided from the collected data and reported to individuals in contact with a person infected with COVID-19 (Sonn & Lee, 2020).

Before the pandemic, artificial intelligence and smart cameras equipped with facial recognition technology were used to identify criminals and prevent crime. The pandemic intensified the need to use such technologies (Costa & Peixoto, 2020). In Wuhan, through the QR code system, data such as body temperature have been integrated with the contact history of people, and people's health status is divided into three groups: green, yellow, and red. Therefore, the decision regarding the quarantine of the citizens would be made quickly. Infrared cameras and face recognition systems are used to online monitor people with symptoms (AlTakarli, 2020). The self-quarantine safety protection program enabled by GPS technologies was also used to quarantine patients more effectively (Inn, 2020).

E-learning and teleworking: The COVID-19 pandemic had a more severe impact on educational and job market than previous crises. From the early days of the pandemic, many companies around the world followed the teleworking implementation of their employees, following WHO guidelines for social distance. Companies help manage the crisis by teleworking their employees while taking care of their health. The International Labour Organization (ILO) defines teleworking as using ICT with tools, including smartphones, laptops, and desktops, and performing tasks outside the workplace (Belzunegui-Eraso & Erro-Garcés, 2020). More than 1.6 billion students have been affected since the outbreak of COVID-19. In order to continue the education process, e-learning and online classes were adopted in different cities. ICT-based distance learning in the context of social networks, mobile applications, and video conferencing for student-teacher communication are implemented (Hassankhani et al., 2021).

Smart mobility: COVID-19 strengthened data-driven urban management and helped plan and manage mobility (one of the major cities challenges) that is more critical throughout the pandemic. Online monitoring of urban transport status well demonstrates the temporal-spatial distribution of traffic and is used to manage traffic in various cities, including Lisbon and New York (Alpalhão et al., 2021). Expanding existing routes and creating new cycling paths are other measures of smart cities (such as Berlin, Madrid, and London) in the COVID-19 era. In Funchal, automatic traffic counters and environmental stations were used to collect city mobility patterns data, which was also served to monitor traffic during the quarantine period. Controlling and managing the occupancy level of public vehicles is another solution of smart cities. In Germany and Spain, a new feature has been added to the bus app letting users know the bus occupancy level for a specific trip at a particular time. Hence, when the bus is busy, users can select other vehicles (EIT Urban Mobility, 2021).

Smart environment: The smart environment became important during the COVID-19 pandemic in improving medical and household waste management and

socializing environmental protection programs. The smart environment utilizes the capacity of citizens and the government to help meet new environmental challenges through technological solutions and innovation. Although the COVID-19 pandemic improved the environmental quality of cities by temporarily reducing air and water pollution and greenhouse gases, the challenge of household and medical waste and water and electricity consumption at the household level soared as a result of the homestay. Jakarta Province, with its integrated smart city platform, has made it possible for citizens to contact call centers to collect household infectious waste. In addition to waste management in this province, the process of obtaining environmental license is online via sending videos or photos. Using social media to educate, raise awareness, and conduct various environmental campaigns is another effective measure of smart cities during the COVID-19 pandemic (Rachmawati et al., 2021).

Smart monitoring: Health data is collected through screening and monitoring by smart sensors from various locations, including airports and public transportation terminals and health centers. Analyzing such data helps to plan and make health decisions. Advanced technologies, including block-chain and quantum cryptography, not only increase the amount of collected data but also do not violate privacy and safety of individuals (Allam & Jones, 2020). IoT-enabled devices, including sensors, wearables, software, and cell phones, collect data from different places across the city. Big data obtained with AI is used to analyze trends and discover different algorithms. The use of big data before the pandemic was common in the preparation of traffic reports, and from the beginning of the pandemic, the importance of integrated use of data in the healthcare system has increased (Kummitha, 2020). For instance, the United States has integrated health data collection devices and systems into the National Healthcare Safety Network (Allam & Jones, 2020).

Adoption of Smart City Technologies in Tehran Prior to the Advent of COVID-19

Having an approximate population of nine million, Tehran is the capital and largest city of Iran, having a share of more than 25% of the Iran's economy. By 2025, Tehran is expected to be on the list of 30 most populous metropolises in the world. Challenges such as rising energy consumption, air pollution, and heavy traffic have reduced the quality of life in Tehran. Low citizen participation in paying tax, limited government financing programs, and unsustainable sources of income are major challenges of urban management in Tehran (Fartash et al., 2021). The focus of services development and smart management within the city includes smart and clean transportation and smart management of waste, energy, and environment. The focal point of municipality digital transformation is to create open and shared access to urban data and promote transparency and development of infrastructure and communication networks (Smart Tehran, 2020a).

Smart Tehran is a comprehensive program that addresses the challenges and problems of the city and its citizens. Urban smartening is a multidimensional and dynamic issue which aims to improve citizens' quality of life by using technology

and infrastructural development. Smart Tehran Strategic Council is the policy-making body, and Smart Tehran Center, which was established by the Tehran Municipality ICT Organization in 2017, acts as the executive body of Smart Tehran. The axis of smart city and digital services includes two projects of MyTehran platform and Baham citizen participation platform. Such platforms integrate citizen access to services and promote their participation as well as their interaction and engagement in urban management decisions.

Some important programs of smart city in Tehran are as follows. Tehran smart wastewater and waste management includes four modules, i.e., public supervision and control system, worker organization system, vehicle tracking system, and status reporting system (TMICTO, 2019). In Tehran's new traffic regulation which determines the share of cars entering (20 days in each season for each personal car) in the central part of the city, a smart traffic control system was launched. The smart system of car park in Tehran is being completed. In the traffic control system, users register their vehicle details and access facilities including the information at the nearest parking place and pay their parking fees online (TMICTO, 2018). The "Tehran Data View" system (data.tehran.ir) provides statistical data and updates urban information free of charge and without any restrictions. The open data policy has been implemented in Tehran with the aim of increasing the responsibility and accountability of city managers and promoting transparency (Smart Tehran, 2020b). The Smart Tehran API system (api.tehran.ir) was also launched with the aim of facilitating the access to innovative companies and startups to municipal data and services. This measure reduced costs while increasing the quality of public services and helped to strengthen businesses related to urban services (Smart Tehran, 2020c).

Application of Smart City Technologies in Tehran Throughout the COVID-19 Pandemic

Amid the outbreak of COVID-19 around the world, the normal lifestyle and the provision of public and business services to the citizens of Tehran were challenged. Such challenges, of course, provided an opportunity to play a more active role in the functions of the smart city and its development in Tehran. Although the implementation of the smart city in Tehran was in its rudimentary phases, the pandemic conditions and the need to provide online services accelerated the smartening process. The goals of these programs are to transform Tehran into a sustainable city for citizens along with continuously increasing life quality by attracting citizen participation, efficient urban management, and a dynamic urban economy. Success cases in Tehran have commonly adopted ICT, i.e., smart city, in the COVID-19 period which will be further discussed in this section.

From early 2020 and simultaneous with the outbreak of COVID-19 in Iran, the business environment and startup ecosystem were affected. Many startups suffered as a result of widespread shutdowns and restrictions. In this regard, and with the aim of reducing the consequences of the pandemic, innovative plans, services, and products in the form of Corona+ program were designed and implemented by the

Science and Technology Vice-Presidency. The key goals of this program are (1) identifying and evaluating digital and online startup capabilities in pandemics; (2) improving capacities to better serve the community during and post-COVID-19; (3) stabilizing the capacities of digital startups; and (4) development of startup network. Corona+ was launched in March 2020, and its priority support fields include online health, online sports, online education, online entertainment and tourism, online social innovation, and online stores.

Special advantages and facilities are given to selected ideas and technological solutions of this program, including speeding up the process of obtaining knowledge-based licenses and various incentives, financial and legal supports, as well as the provision of technical and physical infrastructure. About 700 projects applied for the Corona+. Eventually, 355 projects were approved and got support. Among the registered projects, 135 projects are pertinent to online retail, the highest area with 26% of the total projects. Online sports-themed projects were also ranked lowest in frequency with 16 items and 3% share. Corona+ facilities and financial support were provided to companies in two main categories: product development and market development. A total of 179 companies were approved, and \$2.7 million (1 US \$ = 42,000 Rial (Iran's official exchange rate accessible at www.cbi.ir/ExRates/rates_fa.aspx) have been funded so far, of which 37% is product development and the remaining 63% is market development. Online health companies with the 23% share have received the most support until now. The following are some highlights of COVID-19's influential businesses (Iran Vice-Presidency for Science and Technology, 2020).

Tritapp startup was formed in the field of health with the aim of providing an environment for interaction between doctors and other health workers. From the start of the COVID-19 outbreak, the platform was launched to connect Iranian and Chinese doctors with more experience in dealing with the pandemic (Iran Vice-Presidency for Science and Technology, 2020).

Mask is a free application to control and prevent the prevalence of COVID-19 in Iran. Using mobile apps to diagnosis and quarantine is a successful experience (in countries like China and South Korea) in controlling COVID-19. The developers of this application include a team of software and virology specialists. This application shows the possibility of viewing online and real-time COVID-19 outbreak status in cities, which is effective in awareness and distance from virus-infected areas. Patients' information, their place of residence, and their mobility are drawn based on the data of cellular phone operators. This application works well in terms of the possibility of contracting COVID-19 based on the location of the users and also informing the users about contacting the infected with COVID-19. User identity information in this application is considered confidential, and users' privacy has also been highly respected by its developers (IRIB News Agency, 2021).

Another example is Balad application. Balad is a smart map and router using online traffic data to provide the fastest route to destination. Simultaneous with the start of public vaccination in Tehran in June 2021, facilities and features in this regard were added to the application. Such features include showing health centers on the map, adding vaccination centers, showing the crowds and types of vaccines

available in each center, and the ability to ask and answer questions by users. These features were highly praised by citizens in Tehran, and about 15 million referrals were made to the information of vaccine centers through this application. In the Q&A section of this application, 70% of questions received at least one answer. More than 7000 users mentioned their suggestions and experiences from the vaccination centers (Balad, 2021).

Considering the importance of social distancing in the management of COVID-19, online municipal services were provided through the MyTehran website and application. Having three million users, the app operates in three main areas: participation, citizen service, and municipal digital transformation. This application is an integrated platform for online services of Tehran Municipality and communication with citizens. Diverse services provided in this application include citizen electronic wallets, car and traffic regulation services, technical inspection, sale of subway and intercity bus tickets in barcodes and on mobile phones, payment of service bills and mobile phones, the possibility of accessing more than 70 online stores and online businesses, public monitoring 1888, sending public reports and follow-up troubleshooting by submitting requests and sending photos, paying municipal tolls, accessing a map of Tehran for routing and providing data about important public places such as medical centers and hospitals (TMICTO, 2021b).

Bike app is another example that was presented in collaboration with the municipality and the private sector. The application was developed in the spring of 2020 to develop and facilitate cycling as well as observing social distance. The Bike application is the starting point for promoting cycling to citizens of Tehran. Citizens' behavior and lifestyle are expected to be gradually affected by the increasing share of bicycle in intercity travels. Bike features and capabilities include smart navigation and providing optimal routes; the possibility of sharing routes; sending images by users on the application social network; viewing the nearest bicycle parking, repair shops, and shared bicycle stations; etc. One of the important features of this application is holding a campaign to know the roads and make it enticing to users in order to send data. The Bike app won the Smart Mobility Award at the fourth edition of the WeGo 2020 global event (TMICTO, 2021a).

A summary of smart city technologies and initiatives in Tehran and the rest of the world to mitigate the COVID-19 pandemic is illustrated in Table 2.

Challenges of Adopting Smart City Technologies in Tehran

The general challenges of implementing smart cities are classified into four categories: financial, governance, technical, and social. In the category of financial challenges, the most common barriers are high investment costs, uncertainty of profitability, and lack of incentives. Lack of coordination and communication between stakeholders, restrictive regulations, and instability of laws or managerial changes are challenges of governance. Lack of specialized human resources, maintaining security, and data integration are deemed as the technical challenges of cities. In the social category, cities also are coping with issues such as low citizen

Table 2 Smart city technologies in Tehran and the rest of the world to mitigate the impact of COVID-19 pandemic (author's conclusion)

Smart city technologies	Application of smart city technologies and solutions	Instances in Tehran	International instances
1. Smart healthcare	Telemedicine support	4030 system, Snapp app	Varanasi; Jabalpur; New York
	• COVID-19 online counseling service for patients and doctors	Nursino Tritapp	Wuhan
	• Develop application for vaccine registration	Ministry of Health website	Jakarta
	• Develop a medical calling robot to deliver extra healthcare and treatment	–	South Korea; Italy
2. Contact tracing and tracking	• Track and trace of suspected and positive cases	Mask app	Singapore (TraceTogether app); Surat; Hangzhou (City Brain app); Canberra (COVID Safe app); Istanbul; Milan
	• Creating wearable device to empower contact tracing	–	China; India
3. Smart monitoring and restriction	• Night traffic restriction monitoring and measuring physical distancing	Done by traffic police	Stuttgart; New Castle
	• Using biosensor patches as wearable devices to gather health information	–	Megacities in China and the United States
	• Real-time monitoring of citizens through QR	–	Megacities in China; Cannes
	• Using facial recognition platform and street infrared camera system	–	Wuhan
4. Quarantine management	• Daily contact with quarantined people and patients by smart applications	–	Jabalpur; Pune
	• Using mobile application to monitor people who should be quarantined via GPS	–	Big cities in South Korea
5. Teleworking and online education as a new normal	• Facilitating teleworking for civil servants as well as private sector employees	*	Many big cities worldwide
	• Rapid development of infrastructure for online teaching in schools and universities	Skyroom platform Findo	Singapore; Tokyo

(continued)

Table 2 (continued)

Smart city technologies	Application of smart city technologies and solutions	Instances in Tehran	International instances
6. Online services	<ul style="list-style-type: none"> ● Digitalization of services ● Integrated municipal services through mobile applications for paying utility bills, mobile phones, and city tolls 	Tehran electronic book fair; MyTehran app	Many big cities worldwide Lisbon (Lisbon 24 app); Bengaluru (INDEX app; BBMP app)
7. Smart mobility	<ul style="list-style-type: none"> ● Designing dashboards as a framework for monitoring data 	–	Lisbon; New York
	<ul style="list-style-type: none"> ● Enforcing wearing mask obligations by artificial intelligence in public transportation system 	–	France
8. Smart environment	<ul style="list-style-type: none"> ● Waste pick-up service through mobile apps/call centers to minimize the mobility of people 	Smart waste management apps, e.g., ZarPlus Jaroob	Jakarta

participation and lack of motivational factors (TMICTO, 2021c). Challenges of implementing smart city in Tehran can be discussed in two time periods pre- and post-COVID-19. The subsequent section, “Conclusion,” addresses the challenges of smart city implementation in Tehran prior to the COVID-19 and particularly throughout the COVID-19.

In the dimension of smart governance, key challenges that Tehran faces include the lack of integration in the urban management decision-making system, the lack of an integrated monitoring system, the mismatch of authority and responsibility, and the lack of transparency in the results of different institutions. The multiplicity of executive bodies who make decisions leads to the lack of coordination and parallelism. Another challenge is the lack of an integrated monitoring system (Khansari et al., 2015).

Challenges related to smart city infrastructure in Tehran include lack of ICT and urban infrastructure and integration of data platforms across sectors including transportation, waste, and energy. Regarding the need of integrating infrastructure, maintaining the security of citizens’ data (including debit cards, terminals, and data centers) should be considered in Tehran. Low Internet speed and bandwidth in some parts of Tehran is another challenge in implementing a smart city (Fartash et al., 2021).

Citizens are the most important component of a smart city. Participation of interested citizens in the promotion and implementation of smart city technologies in Tehran deserves more attention. Education and culture-building through educational and promotional programs in social media and urban advertising increase the speed of acceptance and adaptation to smart city changes (Haghghi et al., 2018).

Additionally, so far, there has been no suitable system for encouraging the participation and suggestions of the citizens of Tehran.

Economic problems in Iran have challenged the implementation of Smart Tehran project that required high investment. Also, the services and products of the smart city in Tehran should be more appropriate with the needs of citizens (Fartash et al., 2021). Environmentally speaking, Smart Tehran lacks an efficient monitoring system and accurate criteria in line with the goals of the projects to measure performance. Identifying environmental parameters and measuring them also must be taken into consideration (Haghghi et al., 2018).

During the COVID-19 pandemic, the challenges of implementing smart cities and the smart urban ecosystem in general focused more on data collection, analysis, and integration infrastructure. The lack of coherent regulatory policies and procedures in emerging technologies, including standards for the collection and privacy of user data, became more important during the pandemic (Gupta et al., 2021). Tehran in particular lacks effective policy framework and regulations for digital technologies. Deploying smart devices and sensors in Tehran have high operating costs. In addition, fault tolerance, resilience, and high energy consumption of mobile communications are other challenges in implementing Smart Tehran in the COVID-19 era. Lack of inclusiveness and access to digital technologies increase social inequality which deserves further attention in Tehran (Hassankhani et al., 2021). Data integration and lack of financial and skilled human resources pertinent to smart city technologies are other notable challenges in this regard.

Conclusion

The COVID-19 outbreak has turned into a serious and pervasive crisis for cities across the world. Due to the high speed of transmission, limiting crowd, and social distancing, many services and jobs and even education in schools and universities became online. Smart city technologies played a pivotal role in preventing the spread of pandemic in Tehran and also in the smart cities around the world. Smart cities equipped with a variety of technological and innovative facilities and tools provided faster and more efficient responses to the consequences of the pandemic. This chapter reviews international experiences in regard to adopting smart city technologies and also explains Tehran's experience in detail.

Smart Tehran, which is a new initiative in Iran, has taken important steps toward effectively confronting and preventing COVID-19 by offering various solutions. Based on this chapter's findings, some recommendations are provided to strengthen the capacity and applications of smart city technologies in Tehran to better overcome future health and natural crises.

- Empowering economic and business ecosystem and establishing smart monitoring and warning mechanisms to predict, identify, and deal with the probable future crises

- Establishing specialized working groups at governance and citizen level, to consult and provide creative solutions to solve the problems and challenges caused by crises
- Capturing citizens' trust by increasing the efficiency of urban services, creating mutual trust, and increasing urban resilience with smart city plans and actions
- Implementing structural reforms, integrating governance, collecting and applying the data, and reducing parallel work along with speeding up urban decision-making by improving smart city infrastructure

Abstract

India has been frequently fraught with a substantial degree of severity of both natural and man-made disasters, which have taken a heavy toll on the lives and property of millions of people rendering them homeless and jobless and leaving them with deeply ingrained reflections and memories of pain and trauma which may even take generations to be healed completely. For thousands of years, the arts and crafts have been widely recognized as a medium of interaction, self-expression, empowerment, and resolving conflict by binding together various elements of the society, culture, heritage, environment, and ecology of a region. Thus, there is a dire need to understand the existence of arts and crafts not only within their cultural context but also in terms of their therapeutic usefulness and empowerment aspects in strengthening the voices, sustaining identities, and building capabilities of the disaster-affected victims by exploring various aspects of artistry and creativity associated with a particular craft.

In this context, the present study attempts to (i) present a historical narrative of the role of visual arts in mitigating the after-effects of some of the prominent disasters in India by promoting a speedy process of recovery and normalcy of the affected victims over a period of time and (ii) eventually propose resilience-building policy recommendations by the inclusion and promotion of Indian arts and crafts as an important tool in the post-disaster recovery and redevelopment process in mitigating disaster-related aftermaths in India. The study is conducted by holding a series of discussions with some of the well-known NGOs and individuals working in the field of visual arts through telephonic and virtual conversations. Data is analyzed by applying the thematic analysis method.

Arts and crafts · Healing · Disaster · India · Visual arts · Trauma · Covid-19

Introduction: Healing and the Arts and Crafts

According to a UN research, India endured the fourth highest economic loss in the world, or \$79.5 billion, as a result of natural catastrophes that happened between 1998 and 2017. The National Disaster Management Authority (NDMA) revealed that about 5700 kilometers of India's 7516 kilometers of coastline are still vulnerable to cyclones and tsunamis of varied intensities and more than 40 million hectares are at risk of flooding and soil erosion. Not only this, but India has also been fraught with a substantial severity of man-made disasters as well, such as communal riots, wars, and terrorism, and most recently the devastation and havoc caused due to the global pandemic Covid-19. This has taken a heavy toll on the lives and property of millions of people rendering them homeless and jobless and leaving them deeply ingrained with the reflections and memories of pain and trauma which may even take generations to be healed completely. Arts and crafts not only serve as an excellent medium of provision of inexpensive employment opportunities to the victims of the disasters but also have a great potential toward rapid healing of the affected people and resilience building of the affected communities.

According to the famous Chinese philosopher Confucius, one's experience of pain and grief has the potential to serve as the most potent source of creation and change, and that is where exactly the crucial role of healing through arts and crafts comes into play. Arts and crafts constitute an indispensable intangible component of the cultural heritage of a place which is known to play an important role (though hardly acknowledged) in resettlement processes, ability to restore the social fabric, effectively maintaining and managing cultural variations, encourage intercultural discussion dialogue, and enabling the effective monitoring of cultural change in post-disaster situations. The United Nations Educational, Scientific and Cultural Organisation (UNESCO) proposed in its recently released position paper (2018) on "Culture in City Reconstruction and Recovery" a CURE framework which highlights the importance of mainstreaming "culture" into all the fields and areas

of invasion and in all the phases of the reconstruction and healing period, including needs assessments, scope definition, making plans, funding, and execution. This was developed with the belief that while existing place-based solutions emphasize the restoration of physical assets, integrating “culture” increases a sense of belonging to community, as well as its viability and sustained life in the physical environment (UNESCO, 2018). However, there exists a dearth of systematically theorized or evaluated studies at both the national and international levels in this regard.

According to some of the most well-known literary works in this area, arts and crafts are a significant means of facilitating the retrieval and reprocessing of traumatic memories, which are frequently encoded in the imagery of a disaster’s experience rather than in words, while on a larger scale, they can aid in rewriting a collective account of a catastrophe and inspire people to take charge of their lives again (Jones et al., 2018). Thus, the arts and crafts of any place bind the society, culture, heritage, environment, and ecology of a region and thus play a pivotal role in mitigating the challenges of a disaster or a crisis situation by enhancing our understanding of the entire ecosystem and implementing a wider recovery mechanism to promote sustainable livelihoods of the most vulnerable and neglected communities of the society. They are transcultural expressions of iconic symbols that have persisted over history and across cultures. They are representations of human consciousness that are typically visual, kinesthetic (dancing), verbal (poetry), or musical (song, music).

Post-disaster Recovery Through Visual Arts

For thousands of years, various civilizations and religions have used carved idols, charms, holy artworks, and symbols to aid in healing. But it wasn’t until the middle of the twentieth century that art therapy became recognized as a distinct and popular therapeutic strategy (The emergence of art therapy as a profession arose independently and simultaneously in the United States and Europe. The term “art therapy” was coined in 1942 by a British artist Adrian Hill, who discovered the healthful benefits of painting and drawing while recovering from tuberculosis. Margaret Naumburg, Hanna Kwiatkowska, Florence Cane, Edith Kramer, and Elinor Ulman were five influential writers of the 1940s who made significant contributions toward the development of art therapy as a recognized field. They have used a variety of methods which include creating community murals (Argue et al., 2009), open studio approaches (Block et al., 2005), art-based large group dialogues (Lark, 2005), mask making (Allen, 2007), installations (O’Rourke, 2007), and ritual (Warner, 2001). Maya Angelou, Frida Kahlo, Marcel Proust, and Edvard Munch, all recognized as masters in their respective disciplines, are just a handful of the many talented artists throughout time who turned unfathomable human suffering into riveting works of art.). The artists have served as commentators on and chroniclers of disaster, war, famine, disease, and other forms of crisis who have portrayed the disasters simultaneously: beautiful and utterly destructive; terrifying and awe-inspiring; devastating and healing. Disasters may represent an “end” and a “new beginning”

simultaneously. An artist probably acts as a first responder to a natural/man-made disaster and can help people develop emergency plans after hurricanes, floods, tsunamis, and other such types of natural disasters. Their work does not provide us with the answers to the questions that disasters raise; rather, it encourages us to investigate the forces that may simultaneously serve to remind us of our capacity and fragility in the face of natural disasters, technological mishaps, and terror. In doing so, it helps the disaster rescuers take charge of their thoughts, emotions, and stories, starting the protracted process of recovery. As a result, art therapy, which uses art as a means of symbolic communication, is a field that is expanding and gaining tremendous momentum in the domain of mental health care. The framework is based on the idea that brainstorming, which serves as a vehicle for instinctual expression, can aid in resolving internal conflicts, fostering self-worth and self-awareness, lowering stress levels, and restoring a sense of general physical, emotional, and social well-being. Using creativity as a framework, they support posttraumatic healing (Tedeschi & Calhoun, 1996; Serlin & Cannon, 2004), progress through adversity (Joseph & Linley, 2008), hardness (Maddi & Hightower, 1999), optimism and resiliency (Antonovsky, 1979; Epel et al., 1998), and self-efficacy. Art therapy has three main benefits for a disaster-affected individual: it (i) gets involved the human body in stress relief through the use of art supplies; (ii) allows the patient to engage in a customized introspective activity where the process and final product serve as "symbolic containers of traumatic memories"; and (iii) fosters cognitive perspective through discussion of the artwork (Sarid & Huss, 2010). Art therapists have shown that they can enhance empowerment, community engagement, problem-solving abilities, and self-esteem in the citizens as well as create a safe environment, decrease stress, and foster a sense of community (Hocoy, 2007; Allen, 2007; Argue et al., 2009; Feldman et al., 2014; O'Rourke, 2007; Warner, 2001). They combine the components of the body, communication, mind, and spirit and allow for the growth of a holistic person. With its many benefits, art therapy today has become a staple of many rehabilitation centers, mental health facilities, crisis centers, private practices, and schools, as well as many other communities and social institutions that have the mission of promoting health, wellness, and growth. While art therapy is immensely helpful in treating adults suffering from any kind of trauma due to various reasons, it is also helpful for treating youngsters, who frequently lack the social and verbal skills to convey their feelings, especially when they have gone through any form of trauma (Hussain, 2010).

In the light of the above discussion, the present study attempts to (i) present a historical narrative of the role of visual arts in mitigating some of the prominent natural and man-made disasters in India and examine which of the Indian traditional paintings/sculptures have played a prominent role in this regard and (ii) eventually propose resilience-building policy recommendations by the inclusion and promotion of Indian arts and crafts as an important tool in the post-disaster recovery and redevelopment process in mitigating disaster-related aftermaths in India. In the literature, the visual arts have primarily been associated with healing because they are utilized by victims to express their feelings and express their emotions (mainly psychological issues, traumatic experiences, depression, and emotional dis-balance).

It is called diversional therapy (i.e., taking your mind off the pain and away from the negative thoughts). There are two ways to pursue it, individual narratives and group narratives, and the present study attempts to present the case of both. Using a qualitative descriptive approach, the study was conducted by undertaking interviews with the well-known NGOs and individuals working in the field of visual arts in India. Thematic analysis is applied to the data to identify themes by utilizing different semi-structured questionnaires for the different category of respondents.

Case Studies of Visual Arts from India

India, endowed with its rich and glorious legacy of visual arts throughout the ages, has one of the most apt and suitable traditional as well as modern art therapies which can prove to be immensely beneficial in advocating and devising post-disaster recovery mechanisms for the disaster-affected victims not only in India but across the world owing to the fact that the Indian paintings have been not only the canvas for the individual artists but also the repositories of community narratives as well. *The following are narratives from some of the respondents:*

When I colour during therapy, it creates a safe space for me to express painful feelings from my past. Colouring engages a different part of my brain that allows me to process my trauma in a different way. I can even talk about the most difficult memories of my sexual abuse without panicking. - *One of the communal riot-affected victims in Gujarat*

For me, during those tough times, painting served as a distraction and a way to numb myself from anything negative. Because it was always stressful for me to see the aftermath of the Covid-19, it has given me many positive thoughts and escaped me from many negative thoughts. - *One of the artists from Madhubani District, Bihar*

The following sections reveal the healing potentialities of the rich Indian traditional paintings in case of different disasters faced by the different communities across India.

Madhubani Paintings of Bihar

In North Bihar, about 76% of the population lives under the threat of floods, making it one of the most flood-prone states of India. Madhubani paintings or more commonly known as the *Mithila Art* is the most popular visual art form of India that originated in the Madhubani district of Mithila region, Bihar, and has ~~majorly~~ strongly come to the rescue of the flood-affected communities in Bihar in terms of both therapeutic healing and creating sustainable livelihoods for them. It is one of the oldest forms of art in the world dating back to 2500 years old. When the biggest earthquake recorded in history – a magnitude of 8.0 – occurred in Bihar and other parts of Nepal in 1934, it was then that this art form was found and first brought to the attention of the public. William G. Archer, a British colonial officer in the Madhubani district of Bihar, discovered these paintings while assessing the damage

brought on by the natural calamity. The British officer published multiple essays and black-and-white images of these paintings, which caught the attention of the outside world. Eventually, Madhubani paintings received national recognition in the year 1975 when Sita Devi received the National Award and Jagdamba Devi, the Padma Shri Award by the President of India. These paintings have been a symbol of love, devotion, tradition, fertility, and prosperity depicting various local and global issues alike.

Some of the disaster-prone situations and social problems where Madhubani paintings played a key role in mitigating post-disaster-related issues and challenges are as follows (Table 1):

- (i) It played a crucial role in the conservation efforts in India in 2012, a year marked by frequent deforestation in Bihar. This campaign was initiated by Gram Vikas Parishad, an NGO headed by Shashthi Nath Jha, in an effort to save local trees that were being cut down for new roads and construction. The trees were originally decorated with depictions of gods and other religious and spiritual figures, including Radha-Krishna, Rama-Sita, scenes from the Ramayana and Mahabharata, and other figures from myths of the same kind. The Indian civilization attained philosophical heights for the power of love, longing, and serenity through these representations. The utilization of abundantly available raw materials and the examination of the relationship between environment, culture, and the human mind are what make Madhubani paintings so beautiful.
- (ii) Mithila folk ladies convey their innermost emotions, hopes, aspirations, expectations, and imaginations through these paintings. At a time when child marriage was rampant in society and that too in the backward regions of the state, a lot of child widows were prohibited to wear colorful clothes. These child widows expressed themselves through Madhubani paintings and painted their lives as they wished to live. Not only this, but the art form has also enabled many women in these regions to empower themselves and live a life of dignity. After struggling to combat the orthodox ideas and traditions that surrounded them for a long time, these women were finally able to take a stand for themselves by becoming financially independent with the help of Madhubani paintings. Finally, they had something which they could call their own which led to the psychological and material well-being among these women.
- (iii) There is a ritualistic context in the Madhubani paintings for particular occasions, such as birth, marriage (such as the one depicted in Fig. 1), and festivals such as Holi, Kali Puja, and Durga Puja, which greatly enables the disaster-affected victims to experience the feelings of joy, happiness, and prosperity.
- (iv) Covid-19 has been widely depicted by various artists of Bihar. Pushpa Kumari, a Madhubani artist, produced a series of brand new pieces last year that was inspired by the pandemic-related events. The Covid Bride is one of the most remarkable of these; it is a complex piece that is richly observed. A classic Mithila bride in the one-eyed Madhubani profile stands in the foreground. She is portrayed clutching the Earth in her hands while donning a mask in an effort to protect it from Covid-19. At the bottom of the piece, a line of trains transports

Table 1 Therapeutic impact of Madhubani paintings, Bihar

S. no.	Indicators	Details of the art form
(1)	Purpose (personal/social/religious/ritual)	To transmit deep social and religious messages among the societies To depict rituals during birth, marriage, and festivals such as Holi, Surya Shashti, Kali Puja, Upanayana, and Durga Puja
(2)	Use of major/prominent colors (which are naturally made and give a sense of soothed-ness)	Black – lampsoot White – powdered rice Green – leaves of the apple tree and tailcoat Blue – from the seeds of <i>sikkot</i> and indigo Yellow – singar and jasmine flower Saffron – bark of peepal tree Red – kusum flower and red sandalwood
(3)	Most commonly used geometrical shapes/patterns/designs/figures	Figures of Ram and Sita, Radha and Krishna, and Shiva and Parvati Figures of peacock, lotus, tulsi (sacred plant), sun, and moon are the most common Flowers, animals, birds, and all types of geometric patterns Scenes from the royal court Two-dimensional geometry pattern which majorly symbolize love, devotion, tradition, fertility, and prosperity The illustrations drawn in these paintings are majorly a reflection of myriad thoughts, hopes, and dreams of the villagers especially the womenfolk
(4)	Building and strengthening “connectedness” (individual/collective works)	The canvas of painting today has shifted from mud walls to paper, fabric, wood, handmade paper, and ceramics indicating that through years of generational connectedness, the paintings today also have shifted toward individualism and depicting individual issues
(5)	Targeted groups	Majorly women-centric craft of India
(6)	Mitigation in disaster (natural/man-made)	
	Man-made	Major products/expressions which marked the event/disaster
	Covid-19 (2019 onward) ^a	Paintings on masks (carrying motifs of birds, fish, and floral designs) Paintings depicting vaccine advocacy Paintings depicting role of doctors and lives amidst Covid-19
	Champaran Satyagraha	Paintings depicting Kharau of Mahatma Gandhi and his leadership role in Bihar and India Contribution of women in Champaran movement
	Ghadar Mutiny	Valiant uprising against the British Rule

(continued)

Table 1 (continued)

S. no.	Indicators	Details of the art form
	Natural	Major products/expressions which marked the event/disaster
	Earthquake of Bihar (1934)	These wall and floor paintings were first identified by the British colonial officer William G. Archer who sold these paintings (by canvassing it on paper in black and white) to the outer world
	Earthquake of Bihar (1950s)	The villagers under the craftsmanship of Bihar Ratna Sita Devi started making paintings and their livelihoods from them

Source of information: Award winning artists ((i) Ambika Devi and Asha Jha (founder and owner of Kalakriti) and (ii) Remant Kumar Mishra (popularly known as “mask man” of Bihar)); non-award winning artists who have taken up Madhubani paintings as their passion to revive it ((i) Alka Das (commercial artist from Patna), Ankit Jha (Darbhanga), Ruchi Jha and Renuka Kumari (Darbhanga), Itashri Shandilya (founder of MITHILAsmita), and Kundan Roy (Bihar))

Fig. 1 Kohbar painting by National Awardee Sita Devi depicting the ritual of “Marriage”

migrant workers home. An airplane flying across the page represents people traveling and spreading the illness. Multi-award-winning folk artist Ambika Devi’s tribute to the doctors connects the birth of Lord Krishna (a god Vishnu’s incarnation) to the present situation by drawing on the classifications of superheroism, sacrality, and Hindu religious legends.

Fig. 2 “Tribute to Doctors,” by renowned Madhubani artist Ambika Devi

Ambika Devi’s work alludes to the story of Krishna as told in *Krishna Charitas*. Vasudeva (father of Lord Krishna) carries baby Krishna in a basket held above his head as he crosses river Yamuna to save baby Krishna from Kamsa, a tyrant ruler of the Vrishni kingdom, who is determined to kill all the children of Vasudeva and his wife Devaki. In this painting (Fig. 2), it is a physician who carries a group of people in a basket to save them from coronavirus (see virus icons around the physician’s coat). This painting pays homage to doctors and bestows divinity and sacredness to them. Hindu stories are re-circulated, refashioned, and secularized here to convey the superheroic interventions and exemplary work done by the physicians who save not an individual (as in the story) but humanity at large from infection and death. This mapping and re-coding of a religious story to the current moment helps the artist to celebrate the extraordinariness and persistence of the doctors amidst challenging times. The painting is also global (There are several such instances of repurposing religious myths and legends across the globe – Jonathan Muroya, an illustrator based in Providence, for instance, deftly uses Greek gods and the associated myths to capture several aspects of life during the pandemic in his “Greek Quarantology” series.) in that it not only joins other visual arts in paying tribute to the frontline workers but also remains local and quintessentially embedded in the Hindu tradition through the way it utilizes the rhetorical context and traditions of the religion.

Pattachitra Paintings, Odisha

Prints on woven fabrics or scroll paintings are referred to as pattachitra, which is a combination of the words *pata* (fabric/scroll) and *chitra* (drawing or painting). Pattachitras, which are created by chitrakars (artists), are primarily used in Bengal and Odisha in India to express both religious and socio-culturally significant topics. These paintings also date back to 1000 years of age and are one of the oldest among all the traditional paintings that evolved and spread in India. The best works of Pattachitra are found in and around Raghurajpur near Puri in Odisha and Birbhum, West Midnapore, Kalighat, and Bardhaman regions of West Bengal. These paintings are divided into three parts as far as the medium or canvas of these paintings is concerned: (i) paintings on cloth or “Patta Chitra,” (ii) paintings on walls or “Bhitti Chitra,” and (iii) palm leaf engravings or “Tala Patra Chitra” or “Pothi, Chitra.”

Some of the disaster-prone situations and social problems where Pattachitra paintings played a key role in mitigating post-disaster-related issues and challenges are as follows (Table 2):

- (i) *Corona Rakshasa* by Bengal chitrakars Rupsona and Bahadur Chitrakar portray coronavirus as a *rakshasa*. *Rakshasas* (as opposed to gods) in Dharmic religions are malignant demons who are capable of consuming human beings and shifting shapes. Like vampires and medieval monsters in Western mythology, *rakshasas* are wicked beings with a terrifying appearance who constantly come into conflict with human beings and saints. Rupsona and Bahadur Chitrakar’s painting offers a close-up view of corona *rakshasa* with long fingernails, horns, and corona-stricken body and eyes. The painting is presented predominantly in red color and is invested in the Hindu mythology of *asuras* (ungodly beings) not only to suggest the monstrosity and the horror that the virus triggers in contemporary real life but also to imply how the virus, like a typical *rakshasa*, feasts on the blood of helpless victims. While corona icons and sun-looking motifs fill the border of the panel with geometrical regularity, a flying dragon and a multi-colored earth in the foreground suggest the Chinese origins of the virus and the planetary nature of the pandemics. In short, the painting concretizes corona as a *rakshasa* to convey the lethal and the atavistic force of the virus. In so doing, *Corona Rakshasa*, described in the visual language of Hindu religion, provincializes and thus offers a cultural/folk narrative to the widely circulated clinical image of the virus.

The accompanying songs were written by the artists, and they provide the narrative for the pandemic while the scrolls provide the visual narrative. They have largely discussed Covid-19, its consequences, and how to defend oneself from the disease in the most recent scrolls created by renowned painters. They have also voiced their regret and grief at the deaths of loved ones brought on by the dreadful illness. The multi-panel scrolls are unfolded by the performers as they sing. Normally, they would travel to various parts of India and even to other nations to share their stories, but the virus has stranded them in their communities, severely

Table 2 Therapeutic impact of Pattachitra paintings, Odisha and West Bengal

S. no.	Indicators	Details of the art form								
(1)	Purpose (personal/social/religious/ritual)	To depict Hindu mythology based on Vaishnava Sect These paintings were primarily used for worship of the deities when the ritual of “bath” took place for them								
(2)	Use of major/prominent colors (which are naturally made and give a sense of soothed-ness)	Rich colorful application Usage of vegetable, earth, and stone colors Majorly vibrant colors are used such as red, orange, yellow, pink, etc.								
(3)	Most commonly used geometrical shapes/patterns/designs/figures	Creative motifs and designs Portrayal of simple themes A mix of classical and folk culture Decorative borders with the use of flowers and foliages								
(4)	Building and strengthening “connectedness” (individual/collective works)	Three different mediums of painting, cloth, walls, and palm leaves, provide for a spectacular narrative of collective narratives on various socioeconomic issues apart from the Hindu mythological stories								
(5)	Targeted groups	Majorly women-centric craft of India								
(6)	Mitigation in disaster (natural/man-made)	<table border="1"> <thead> <tr> <th>Man-made</th><th>Major products/expressions which marked the event/disaster</th></tr> </thead> <tbody> <tr> <td>Covid-19</td><td>Depiction of deities and common women wearing masks</td></tr> <tr> <td></td><td>Depiction of “Rakshas” resembling “Covid-19”</td></tr> <tr> <td></td><td>Depiction of common life badly impacted due to Covid-19</td></tr> </tbody> </table>	Man-made	Major products/expressions which marked the event/disaster	Covid-19	Depiction of deities and common women wearing masks		Depiction of “Rakshas” resembling “Covid-19”		Depiction of common life badly impacted due to Covid-19

Source of information: Renowned artists of Pattachitra paintings ((i) Apindra Swain and (ii) Swarna and Mamoni Chitrakar).

restricting and curtailing their artistic and creative powers. Sonali is among the artists. Apindra Swain, an Odia Pattachitra artist from Raghurajpur, has produced a number of absurd pieces that are based on Covid-19 safety regulations. One of the artworks has customary elaborate borders and vivid colors. It is composed of cloth and has layers of natural gum, lime, and polish applied with glass bottles. But instead of displaying gods and goddesses as is customary, it shows a woman dressed elegantly, donning a mask, and cleaning her hands in a basin (Fig. 3).

“My heart is breaking,
How will I express my feelings?
The whole world is filled with sorrow everywhere.”.....

We as a community have been making scrolls on current events for a long time now,...So, we thought that when such a virus has hit not only our country but the world, why not make a

Fig. 3 “A Woman beside the Wash Basin,” Apindra Swain Pattachitra painting depicting the case of Covid-19 (a work imbued with a sense of whimsy).

painting or song on it? Because patachitra is a medium of social communication, through our art and song, we reach out to many people. – *Swarna Chitrakar, song sung to Patachitra scroll on coronavirus*

A modest publisher named Tara Books was drawn to Swarna’s artistic talent. She claimed that during Covid-19, they evaluated her work in an online form and asked her to create about 100 little illustrations on the various facets of the pandemic, such as labor migration, individuals living apart from family, etc., for a book that they would probably publish. She added that in addition to addressing how the pandemic is hitting the entire world, not just their hamlet, her work for the book would also contribute to the history of our current era. Swarna expresses optimism in her song for the day when everyone would be present and able to enjoy each other’s company.

Mamoni, another Pattachitra artist, while imagining the post-pandemic world has expressed:

If the scrolls can go somewhere and an exhibition can be held, they could spread not only the message of dealing with the pandemic but foster an appreciation for their traditional art.

- *Mamoni Chitrakar, Pattachitra artist.*

- (ii) Apart from depicting the recent phenomenon of Covid-19, the Pattachitra artists have also painted and sang about current events and issues as well as mythological and natural subjects such as commemorating tragedies like 9/11 and natural disasters such as tsunamis and floods. Others promoted social and health education, such as those that explained preventive measures to take against HIV/AIDS or the deadly coronavirus affecting the world today.

A Brief Account and Role of Other Traditional Indian Paintings in Disaster Mitigation

Warli Paintings

One of the earliest known artistic styles is the Warli painting (Source of information: Non-award winning artists who have revived this art form driven by their passion: (i) Mugdha (Mumbai) and (ii) Balu Mashe (son of renowned Padma Shri artist Jivya Soma Mashe), Warli Paintings). It is a type of tribal art that has Maharashtra as its birthplace. Although this art is particularly well-liked in the tribal community, it has not yet attracted much attention outside of India. A kind of tribal art known as “Warli painting” was primarily developed by Indian tribes from the North Sahyadri Range. Cities like Dahanu, Talasari, Jawhar, Palghar, Mokhada, and Vikramgadh in the Palghar district are included in this range. Despite the fact that the tribal form of art is considered to have originated as early as the tenth century AD, the Warli painting style was not recognized until the 1970s. The idea of “Mother Nature” and natural forces are central to Warli culture. Their primary means of subsistence and a major contributor of sustenance for the tribe is agriculture. Similar to how prehistoric people utilized cave walls as their canvases, Warli painters use the framework of their clay houses as the subject for their paintings. The Warli (Varli) tribes from the mountainous and coastal areas around the borders of Maharashtra and Gujarat practice it as a way of life as well as a form of art. This kind of art, which dates back to roughly 3000 BC, has a mysterious appeal. It now stands out among other styles because of Maharashtrian artists like Jivya Mashe and his sons Balu and Sadashiv who work tirelessly to preserve the art. In reality, Mashe received the Padma Shri in 2011 for promoting the style over the world (Fig. 4).

Warli art inspires us to consider environmental awareness and find delight in the small things in life. The Warli people have a straightforward way of life. They used to worship nature, rely on it for sustenance and daily needs, and had a belief in the balance of man and nature. In order to promote “sustainable” living, many urban

Fig. 4 Warli paintings depicting 'Nature at its Bounty'

residents are now embracing a modest lifestyle that includes avoiding technology whenever feasible, eating healthy, loving handloom, and learning more about the science underlying old customs and traditions.

Phad Paintings of Rajasthan

Phad, a Rajasthani art with a history dating back more than 700 years, is popular due to the oral tradition that surrounds it (Source of information: Renowned artists who have taken up Phad paintings as their passion to revive it: (i) Kalyan Joshi (Rajasthan) and Pragati Agarwal (founder of Art Tree)). Phad paintings are a component of a complex song-and-dance show put on by a couple of balladeers, typically a priest and his wife known as Bhupa and Bhopi from the Rabari tribe of nomadic cattle and camel herders. They play dramatic interpretations of narratives from the Ramayana, the Hanuman Chalisa, and other legendary tales while travelling from village to village with their two-string instrument, the ravanhatta, and using the Phad paintings as visual aids. Mostly practiced in Rajasthan, Phad is a religiously styled scroll and folk painting. The painting depicts the folk deities, Pabuji and Devnarayan, on a long piece of cloth or canvas. Phad is a 700-year-old tradition that has been handed down through one family's generations and has its roots in Shahpura, close to Bhilwara, Rajasthan. After sunset, the Phad artwork would be unwrapped or unfolded, and the performance would then take place in front of the villagers that would run well into

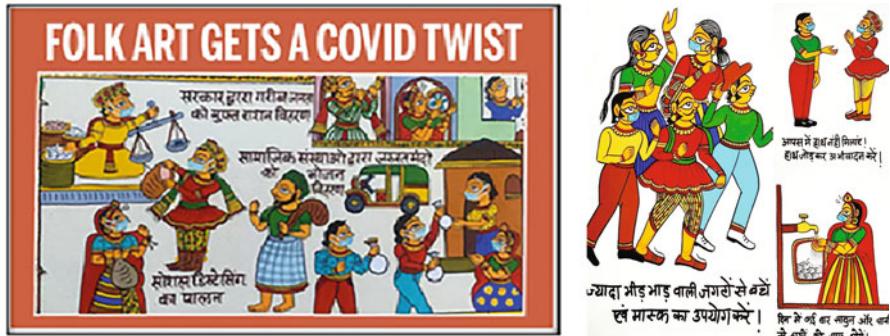

Fig. 5 Phad painting by Kalyan Joshi on wearing masks and social distancing

the night. This may be the origin of the painting's name, "Phad," which in the local language indicates "fold." At the onset of Covid-19, Phad painters Kalyan Joshi and others have taken to depict the troubled lives of the people amidst lockdown, safety restrictions, and widespread migration which can be witnessed from their paintings alongside (Fig. 5).

Kalyan Joshi also worked on a water conservation project in Jhunjhunu in Rajasthan with IDC Mumbai earlier to address the challenges of water scarcity in the state. The greater scarcity of water gripping all the villages nearby was primarily due to lack of knowledge of water harvesting, wastage of water, illegal borings, and evolution of new crop harvesting not suited to the climate and geography of this village, which consumed 100–500 times more water than what was originally produced there. As a result, the water levels were down by 300 feet, and most villages have reached the water threshold. As a result, people started to abandon the villages adding the population elsewhere. The Phad "Narrative Craft" helped in the local way of narration and storytelling of how to save water and recycle and preserve it. This grassroots communication is being done across 10–15 villages near Jhunjhunu, and the artwork has not only been done on the wall of homes in the villages but has been made also on Phad scroll which would be carried and narrated by Bhopa and Bhopi in all these villages about the importance of saving and preserving water. And in a few months, there has been a great water conservation in the entire region.

The Case of Buddha Paintings from Leh-Ladakh Region

There is no denial to the fact that art has no religion attached to it. But when art is discussed in Indian context, it starts taking beautiful religious turns. In the Indian context, it can be said that art is not restricted to a mere mode of expression, but it takes on a higher level where artists and common people choose it as a medium to connect with the "divine." In this world of contemporary art, there are people who let these paintings be the focal point of the energies in their room and, thus, provide them with an energized personal zone to meditate. The best suited paintings for this

Fig. 6 Buddha paintings depicting Peace and Tranquility

purpose are landscape paintings and “Buddha,” Ajanta, and Ellora paintings which give a deep sense of peace and tranquility.

At over 10,000 feet altitude, the barren desert plateau of Ladakh is a fascinating crucible of culture. It is bound on the south by the Great Himalayas and on the north by the majestic Karakoram Range. However, in days gone by, this was not an isolated place; it was an active crossroads of trade in the ancient world. Leh in Ladakh was on an artery of the Silk Route, which flowed from the distant lands of China to those of Mediterranean Europe. This artery connected the Silk Route through Leh and Srinagar to Amritsar and from there down to Nalasopara in present-day Maharashtra and to Kerala. Along with trade, philosophic ideas and optimistic impulses flew to this crucible in the mountains up from Ajanta and Kerala on the one hand and from the cities of China and Central Asia and those of the Mediterranean on the other hand.

A great Buddhist culture was created in this trans-Himalayan plateau. Since very early times, religious teachers from the Pal Kingdom in eastern India and from Kashmir were bringing the ideas of Buddhism to this land. The first great coming of Buddhism which swept across Ladakh onto Tibet, Nepal, Sikkim, Bhutan, and Arunachal Pradesh was in the eighth century. The second great coming of Buddhism was when 108 monasteries were made in Ladakh, Western Tibet, and Lahaul-Spiti in the early eleventh century. Craftsmen and artists from Kashmir were invited to construct and paint these monasteries which were to become the backbone of trans-Himalayan Buddhism. These monasteries are a significant part of the heritage of the world, and they reflect one of the most glorious periods of painting in India (Fig. 6).

Resorting to religion and art is a standing reserve and a natural human response to fear, uncertainty, and existential angst caused by the pandemics. They have time and again reinforced the power of good over evil and thus the cathartic, coping, and reassuring functions of the same. The paintings discussed here repurpose and weave the Hindu religious imageries, stories of the Hindu celestial gods, and extraordinary acts of ordinary people with the Covid-19 pandemics not only to map the cultural anxieties occasioned by pandemics but also to offer the much-needed hope and confidence during the coronavirus pandemic. Also, these folk paintings are textured bio-cultural sites which demonstrate how Covid-19 is not a mere medical/epidemiological event but is also constituted and constantly negotiated within socio-artistic and religious matrices. These paintings, in short, are a testimony of such functions and meaning-making practices and, thus, contribute to the collective grand narrative on contagion.

Concluding Remarks: Building Resilience and Policy Advocacy

While disasters are incidents, trauma is a more accurate way to characterize their impacts. These traumatic incidences frequently irreparably destroy the social and emotional structure, which has a major impact on the entire survival of the people. Resilience is the capacity to bounce back after stress and trauma, to rebuild one's life even after experiencing a devastating tragedy as grief, sadness, and pain which tend to be the natural outcomes of suffering from any kind of adversity and loss (Herman, 1992). The path to resilience involves dealing with the feelings and effects of pressure and traumatic events, learning from them, and reflecting on adversity to increase one's sense of understanding, goal, and compassion in life. It also involves approaching challenges creatively to broaden one's horizons and possibilities for even accomplishing "the impossible" in life. A new theory termed posttraumatic growth (PTG) and the idea of resilience go hand in hand (Calhoun & Tedeschi, 2006). The theory of posttraumatic growth contends that from the breakdown of trauma can come transcendence and that additional growth is conceivable, as opposed to the traditional trauma recovery paradigm, which focuses on returning personal and societal performance to pre-morbid levels of operation (Lev-Wiesel & Amir, 2006; Rosner & Powell, 2006). Stephen Joseph and Alex Linley put up a notion dubbed "Growth Following Adversity" in response to the possibility that posttraumatic growth can come across as being overly optimistic (2008). This idea places significance on the lessons that can be learned through adversity and incorporate them into therapy. Both posttraumatic growth and growth after adversity advocate a method that involves going through stages of loss and repair in order to develop resilience. The visual arts, in particular, has an important role to play here as it helps people re-imagine and re-energize their lives as it promotes intercultural dialogue and respect for cultural diversity which are considered to be the powerful tools for reconciliation and the creation of peaceful societies. Further, it is commonly

understood that the role of the arts and crafts in disaster recovery is simply about cheering people up and providing a short-term distraction through entertainment; however, implementation of various projects worldwide has shown that the arts engender so much more than that and can contribute to long-term outcomes of recovery and rebuilding of the affected communities. (Appendix 1 gives a snapshot of healing effects of arts and crafts at the international level.)

The narratives presented through the case studies of Indian traditional paintings have successfully been able to capture, express, and record life stories met with utter grief, trauma, and the loss of identity and livelihoods and have the ardent potential to develop resilience among the disaster-affected victims at four levels:

- (i) **Physical:** to regain senses of the body in cases of deep pain ingrained personalities which probably lead the victims to the stage of the coma and unconsciousness from short- to long-term spells.
- (ii) **Psychological:** to achieve balance of mind and body and to enable both verbal and non-verbal expressions of the traumatic and depressed victims.
- (iii) **Social/Economical:** to search for lost identity and livelihoods (empowerment impact) and to establish a sense of communication among the individuals within a community or among different affected communities.
- (iv) **Spiritual:** to establish the oneness of mind, body, and soul and search the true purpose and meaning of one's life (existential impact).

The series of “civil conversations” that the visual arts create in the aftermath of disasters not only focus on strengthening of the community values and but also, to a great extent, serve to bring communities together and to engage with the various types of issues the disaster might have brought to light. In this context, it can be clearly advocated that the post-disaster recovery mechanisms/processes in India essentially need to adopt a *culture-centric-based approach* (as envisaged by UNESCO, 2018) to address the different needs, value systems, and mental well-being of the disaster-affected communities made a compulsory part of the National Disaster Management Act (2005) for its effective implementation in the affected areas. It is also to be understood that culture can no longer be considered only as a dividend of development, but rather serves as a prerequisite to its achievement (UNESCO, 2018). A culture-centric approach would also lay the foundations of addressing post-disaster roadmap of economic growth and development which encompasses complex social, culture, and economic transformations within its trajectory. Thus, the culture (in particular arts and crafts of a region/place) should be holistically integrated as an indispensable endowment which can be used as one of the most effective “tools” at all the levels of post-disaster recovery and management mechanisms to achieve resilience and stimulate other development sectors in the disaster-prone as well as disaster-affected areas across India.

Appendix 1

Lessons Drawn from International Experiences

Country	Disaster	Post-disaster recovery model/mechanism	Impact
Australia	Natural: Like Black Saturday bushfires in Victoria in 2009, Cyclone Yasi and floods in Queensland in early 2011	Rebuilding of disaster-affected communities by using arts-led and creative activities conducted by Arts Victoria initiative and the Arts Queensland/Australia Council for the Arts initiative	These projects engaged the affected people and the communities in the process of collaboration, interpretation, reflection, and commemoration
UK	Man-made: Racial conflicts	Research conducted by psychologists at Goldsmiths, University of London	Traditional toys and dolls could work best in helping UK and immigrant kids' friendships to reduce racial conflict
USA and the other adjoining countries	Natural: Hurricanes Katrina and Rita	Hyogo-NOMA Art Therapy Initiative has provided weekly art therapy for over 250 New Orleans public school children (Orr, 2007)	Deeply impacted and uplifted the mental well-being of the affected children who did not have even the access to the mental hospitals
Sri Lanka	Natural: Tsunami	Art therapy was applied to 113 girl survivors between the ages of 5 and 13 who exhibited the most acute symptoms of grief and trauma (Chilcote, 2007)	Art is an effective, psychologically beneficial intervention for children who have undergone significant psychological trauma and one that can be administered cross-culturally
USA	Man-made: 9/11 tragedy	The International Child Art Foundation (ICAF), in collaboration with psychiatrists and psychologists, asked children to use their creativity to reduce trans-generational transmission of trauma and hatred by producing a vision of peaceful coexistence	The effect was positive and helped in healing many children

Abstract

A smart city is one that uses technology, data, and intelligent design to improve the livability, workability, sustainability, and resilience of cities. The concepts of “smart city” and “disaster resilience” are interrelated because, without a disaster resilience plan, it is harder to maintain a sustainable smart city. The term “disaster resilience” allows better anticipation of disasters and proper planning to reduce disaster losses. However, low attention has been given to the “resilience” aspect when defining the term smart cities in contemporary academic dialogues. On the other hand, when discussing various aspects of smart cities, no previous studies

have focused on the ethical aspect of the people who live in those cities. Scholars have discussed the term differently based on their preferences. There is a lack of consensus about the exact meaning of the term “smart city.” Therefore, the purposes of this chapter are to explore the conceptual deficiencies of the term smart city and to highlight the importance of incorporating the “disaster resilience” and “ethical” aspects when defining the term. This is a conceptual paper based on published secondary data. This chapter provides insights for scholars and practitioners to specify the exact meaning of the term for future research.

Keywords

Smartness · Smart city · Disaster resilience · Ethical aspect · Critical review

Introduction

The “smart city” concept has been quite a fashionable and emerging concept throughout the past few decades. Cambridge Dictionary (2019) defines “smart” as having a clean, tidy, and stylish appearance for something. Various scholars use the term to mean multiple things such as smart cities, smart governance, smart education, smart agriculture, smart transportation, smart disaster resilience, IT-led smart infrastructure, smart inclusiveness, and, ultimately, smart well-being of people. Thus, it appears as an umbrella term that contains many broader views.

Despite several discussions about this concept, there is a lack of consensus on precisely what a “smart city” is about. It lacks a clear and sound definition in both empirical studies and empirical applications (Dameri, 2013). Even though there is no clear-cut definition that discusses the criteria that cities ought to meet to be considered “smart,” more cities are nowadays labeled as “smart,” making it controversial about its real meaning (Sikora-Fernandez & Stawasz, 2016). Supported by various literatures, the term smart city is still a fuzzy concept. “Smart city” continues to be a fuzzy concept, frequently used improperly, and weakened with diverse meanings (Caragliu et al., 2011). Though it takes many aspects into account, when defining smart cities, some important aspects like disaster resilience nature and people’s ethics are rarely considered. In this chapter, the authors move forward by generating a comprehensive definition for a smart city by specifying its meaning and including some important yet lacking aspects in existing definitions. There is a lack of discussion on what improves the smartness of the smart city concept. This study tries to specify the “smart city” concept by filling this literature gap. Accordingly, the objectives of this chapter are (1) to highlight the contradictions of the “smart city” concept to specify its meaning and (2) to highlight the importance of incorporating “disaster resilience” and ethical aspects when defining the term. Both aspects will enhance the smartness of the concept.

This conceptual paper is based on secondary data. A comprehensive literature survey permits the comparison of smart city definitions and explores various meanings and definitions to highlight the confusion of the concept. Finally, this study tries to develop a comprehensive definition by specifying essential components of the

smart city and incorporating the ethical aspect in outlining the concept for improving the “smartness” of the smart city concept.

Literature Review

This section begins with a review of the concept’s meaning and flows to its evolution. The latter part of the section analyzes various definitions and discusses the components of a “smart city” to specify the concept’s meaning.

Review of the Concept

Meaning

The term “smart” denotes the standards of good practices (Herrschel, 2013, cited in Rosati & Conti, 2016). The adjective “smart” applies to the concepts of urban technological innovation and the changes that can be made through ICT (Daniel et al., 2016). The smart city idea arises from the application of technology to urban problems. Smart urban development is a strategy used to improve the quality of life in cities by delivering better services to the people using information and communications technology. Though traditional knowledge-based cities focus primarily on education, from the nineteenth century onward, the development of intellectual capital, permanent learning, creativity, and maintaining a high level of innovation, communication, and information technologies started playing major roles in the development of cities (Dewalska–Opittek, 2014). According to Winters (2011), smart cities act as magnets for creative people and workers and allow creating a virtuous circle, making them smarter and smarter (cited in Albino et al. 2015). Also, a smart city is a solution for several existing problems. Prior research done by Gontar, Gontar, and Pamula (2013) suggests the smart city concept to answer the problems of urbanization, aging of social infrastructure in developed countries, and cutting CO₂ emissions. It is also noted that smart cities using high technologies address certain issues like city crowding, pollution, traffic, and poverty (Dameri, 2013). Consequently, a smart city leaves multiple opportunities to exploit its human potential and promote a creative life. The proceeding section examines the existing scholarly definitions for developing a comprehensive definition by incorporating success factors to enhance the meaning of the smart city concept.

Definitions

Many scholars and organizations have defined the term smart city from various perspectives based on their views and experiences. These definitions vary from very simple to comprehend. In simple terms, scholars have identified a smart city as a well-defined geographical area that uses high technologies to create benefits for citizens. A thorough examination of definitions shows that both common and varied ideas are explicit by these definitions. Some selected definitions are discussed below:

Smart cities as environmentally friendly and livable cities, encompassing sustainability and quality of life, also, of course, the composition of technological factors. (Marsal-Llacuna et al., 2015)

The above authors have emphasized the necessity of technological factors to improve the well-being of the people which have been supported by many other authors too. Many previous studies (Sikora-Fernandez & Stawasz, 2016; Gontar et al., 2013; Capdevila & Zarlenga, 2015; Glebova et al., 2014) have discussed the inclusion of information and communications technology (ICT) in defining smart cities. Hence, the use of ICTs is a core in smart cities (Daniel et al., 2016); in addition, many other technological strategies are also applied. According to Daniel et al. (2016), the smart city concept understands ICTs in a very broad sense.

Perhaps, the definition given by Caragliu et al. (2011) provides more insights about how these high-tech applications facilitate the emergence of smart cities:

“Smart city” can be defined as “a city that is sustained based on highly intelligent ICTs and social networking; communication between people and things and things and things, which goes beyond time and space; convergence between ICT and real-time; and convergence with other industries by which new value-added contents and services are constantly re-created accompanied by innovation of society, including work styles, lifestyles, culture, politics, and the economy.

Citing the works of Caragliu et al. (2011) and Capdevila and Zarlenga (2015) have highlighted the importance of using ICT to improve the well-being of the people through participatory governance:

A city is smart when doing investments in human and social capital, traditional (transport) and modern (ICT) communication infrastructure, fuel, sustainable economic growth, and a high quality of life, with a wise management of natural resources, through participatory governance.

Nam and Pardo (2014) argue that a city can hardly become smart with technology alone. Hence, among hundreds of definitions of smart cities, previous authors have highlighted the aspects like technological factors, energy efficiency aspect, governance aspect, quality of life, the well-being of people, and many more. All the aspects are significant to represent the smartness of the cities; however, the consistency among the definitions is lacking.

Moreover, as noted by Madakam (2014), the European city project has identified a six-axis approach to characterize a smart city, namely, (1) smart economy, (2) smart people, (3) smart governance, (4) smart mobility, (5) smart environment, and, finally, (6) smart living. In this study, the smart economy focuses on attractive corporate fiscal incentives, great infrastructure including high-quality domestic and international connections, excellent public services, a high-quality education system, and publicly funded scientific research. A smart environment is defined as a region of the real world that is extensively equipped with sensors, actuators, and computing components. Smart people concept comprises various factors like affinity to lifelong learning, social and ethnic plurality, flexibility, creativity, open-mindedness, and participation in public life. The smart mobility framework emphasizes the travel

choices, reliable travel times for people, travel safety, traffic management in real time, management of passenger transport means, management of car parks, fleet management, management of the use of bicycles, payment of tolls, support in the use of electric vehicles and tracking applications and logistics, etc. Smart governance is basically about using technology to facilitate and support better planning and decision-making in smart cities, and it is about improving democratic processes and transforming the ways that public services are delivered effectively and efficiently. Smart living or simply smart homes are the houses with the sole ability to monitor and adjust environmental systems like heating and lighting automatically.

The literature review revealed that the ultimate promising aspect of the smart city concept is “well-being” and “quality of life” of people on a city. A considerable body of literature discusses the well-being or the quality of life of people because of creating smart cities (Marsal-Llacuna et al., 2015; Myeong et al., 2018; Dameri, 2013; Japan Smart city Portal, 2013, cited in Gontar et al., 2013).

Dewalska–Opitek (2014) also identifies smart cities as a combination of elements: smart economy, smart people, smart mobility, smart environment, and smart living. Hence, smart city is a multifaceted concept (Albino et al., 2015), and it requires a holistic approach to understand it fully. Thus, this study examines whether any additional components need to be included to enhance the meaning of this concept.

Discussion: Enhancing the Meaning of the Concept of “Smart City”

This section summarizes the current state of definitions on smart city concepts and reviews the status of discord among them. The literature review characteristically includes various aspects of a city ecosystem such as smart infrastructure, smart operation, smart services, smart industry, smart education systems, or smart security systems in general. But the common and main component of a smart city seems to be the application of information and communications technology (ICT) for improving the well-being of the people in that city (Table 1).

There is a lack of consensus and fuzziness of the smart city concept. Thus, the current discussion also appears to be consistent with the literature highlighting the issue of consensus in the concept. This definitional confusion in the literature inspired the researchers to examine the concept’s meaning. Hence, the factors essential to making a city smarter and measures contributing to a smarter city are discussed. Many elements and dimensions characterizing a smart city emerged from the analysis of the existing literature, which is depicted in Table 2.

More cities are labeled as smart with the application of ICT. Along with the ICT, a wide range of factors can be identified backstage in accelerating the process of creating the cities smarter. Out of which, it is important to identify the most important features to be focused on in smart cities. But just a few facets alone cannot create a smart city without any regulating and monitoring body. Hence, governments also need to be smart. Meijer and Bolivar (2015) mentioned smart governance as making the right policy choices and implementing those policies in an effective and

Table 1 Imprecise definitions

Description	Scholar(s)	Main critique
“A clear and sound definition of a smart city still lacks, not only in the academic studies but also in empirical applications of smart concepts and projects”	Dameri (2013)	Lack of clear and sound definition
“Even though there is no clear-cut definition which would specify the criteria that cities ought to meet to be considered as such, more cities are nowadays labeled as ‘smart’”	Sikora-Fernandez and Stawasz (2016)	No clear-cut definition
“We still do not have a shared definition of the term; smart city continues to be a fuzzy concept, often used improperly and declined with many different meanings”	Caragliu et al. (2011)	Fuzzy, improperly used, and concept with many different meanings
The definitions posed by cities calling themselves “smart cities” lack universality	Albino et al. (2015)	Lack of universality
There is huge conceptual confusion regarding the smart city concept	Schaffers et al. (2011)	Conceptual confusion
Although ICT and cities have developed, the concept is still under development. Obviously, all those concepts that have been used to denote smart cities are not in total contradiction with each other but are partially overlapping. However, too many definitions mean a lack of focus on the really important factors	Trindade et al. (2017) and Dameri (2013)	Partially overlapping
Although the term smart city has become a buzzword in the last decade, its definition is still unclear. The concept is difficult to define (Odendaal, 2021), and the term is used inconsistently in the relevant literature	Tranos and Gertner (2012) cited in Daniel, K. et al., (2016)	Unclear definition
A significant number of research and literature are imbued with a general idea of what “smart” is in defining smart cities. Hollands (2008) is far more critical of the concept. He has stressed that the main criticism toward the concept is the inability to define what “smart” means in defining smart cities	Daniel et al. (2016)	Inability to define what “smart” means
We still do not have a shared definition of the term or rather the concept of smart city. However, over the last decade, we have multiplied the semantic and operational attempts to	Greco and Cresta (2015)	Do not have a shared vision of a definition

(continued)

Table 1 (continued)

Description	Scholar(s)	Main critique
“bring order” among disparate definitions of the concept and achieve at least a shared vision of a “smart city”		
There is a wide variety of definitions of what a smart city could be; however, a common definition of the term has not yet been stated	Monzón (2015)	No common definition

Source: Literature

efficient manner. Further, a study by Osborne (2006) concludes smart city governance in the mode of four ideal-typical conceptualizations named as the government of a smart city, smart decision-making, smart administration, and smart urban collaboration (cited in Meijer & Bolívar, 2015). Dameri (2013) identifies the presence of governance in special consideration as, in smart cities, the technologies, both ICT and others, to realize high-quality infrastructures, services, and governance processes, to give better results to people. These conceptualizations reflect different theoretical perspectives on the role of government in modern society. Beyond governance, ICT and infrastructures are prerequisites for a smart city, and both together represent the second layer that will serve as a base link to implement the smart city services. Here, information and communications technology acts as a facilitating service. Smart city infrastructure can take advantage of a large amount of data generated from the application of ICT in the domains of environmental monitoring, healthcare monitoring, and transport monitoring (Gaur et al., 2015). There is multiple “e” applications in smart city urban developments, as e-government, e-participation, e-mobility, e-learning, e-health, and e-inclusion (Wolfram, 2012). Today, the most considered component of smart cities is the technology: several types of technology, not only ICT. As an example, the EU SETIS smart city initiative classified technologies concerning four application fields: buildings efficiency, transport, electricity production, heating and cooling. It involves both ICT (e.g., to monitor smart urban mobility) and other technologies, such as smart grids, alternative fuel vehicles, and so on. Further, “smart city” is defined as a city using a set of advanced technologies, such as wireless sensors, smart meters, intelligent vehicles, smartphones, mobile networks, or data storage technologies (Peng et al., 2017, cited in Justina et al., 2019). With all the above, the use of high-tech strategy is also mentioned by some researchers. According to Kehoe et al. (2015), smart grids are also used as a high-tech strategy to alleviate problems such as reducing faults, improving the responsiveness of utility companies to handle demand variations, increasing efficiencies by reducing transmission and distribution losses, and managing cost better. They let customers participate in the energy value chain, by enabling more intelligence throughout the grid. Smart building controls, wind turbines, intelligent lighting, facial recognition, solar panels, low-power semiconductors, wireless charging for automobiles, LED lighting, crowdsourcing techniques, traffic control, and medical alerts are a different kind of technologies associated with urbanization (Deepti et al., 2014). According to Harrison and

Source: Literature review

Donnelly (2011), there are few approaches to smart cities, which have become feasible because of recent progress in technology, such as the use of digital sensors and digital control systems, growing penetration of fixed and wireless networks, development of information management techniques, and development of both computing power and new algorithms.

The creation of ICT-led infrastructure is important to link the smart government with smart cities through the enrichment of success pillars like public safety,

education, environment, healthcare, infrastructure, research and development, sustainable resource management, entrepreneurship, participation in public life, and flexibility of labor market and economic growth. The ultimate result of smart cities is identified as the well-being of people or the enhancement of the quality of life. When the well-being of the people is achieved, that city would be considered a smart city where people can prepare to expose to any disaster and recover from the efforts of a hazard in a timely manner. Thus, it needs to incorporate disaster resilience aspect when defining the term “smart city.”

The Importance of Incorporating the “Disaster Resilience” Aspect When Defining the Term

The above discussion shows how the previous scholars have highlighted various aspects when defining the term. Most of them have given priority to the aspects like IT, infrastructure, environment, etc. Yet, no adequate attention has been given to the disaster-resilient aspect. Some authors have mentioned that urban safety and resilience aspect has been neglected or gained less attention in designing strategies in the fields of smart development (Haan & Butot, 2021; Ristvej et al., 2020). At the same time, some authors have previously claimed that “smartness” and “safety” need to be truly interconnected (Ristvej et al., 2020).

In the context of cities, the term “resilient” refers to the ability of a city to absorb shocks like terrorist attacks and natural disasters and to maintain their usual activities as it is. Modern-day cities are heavily congested in terms of population and physical elements. Though strong development measures took place in the cities, disasters are probable to vanish all the developments (Mohammad et al., 2019). The frequency and the intensity of the disasters that happened in the past few decades are alarming and emphasizing the importance of disaster resilience. According to a study done by the United Nations, almost 890 million people (60%) across the globe live in cities that are at risk from at least one major natural disaster, including floods, droughts, cyclones, or earthquakes (Bansal et al., 2017). The rapid urbanization and growing number of megacities created serious ecological issues like climate change, disasters, and environmental degradation. This greater concentration of people and assets can increase the number of disasters and their impact. As has been explored in the literature, there are cities termed “smart cities” that failed to plan for future threats and had an outstanding lack of planning and preparedness which ultimately cause exceptional damages and losses in an event of a catastrophe (Desouza & Flanery, 2013). Thus, when designing smart cities, considering the disaster-resilient aspect is vital.

Some authors have already identified the significant of this point, and their definitions on smart cities have some insights about this aspect. Patel and Leah (2016) have defined the city resilience as establishing proactive qualities and processes at all levels to mitigate the risks of disasters. For Drobniaik (2012), resilient city can manage disruptions before reorganizing around a new set of structures and have the means of anticipating, preparing for, responding to, and recovering from a

disturbance. For Campanella (2006), city resilience means the capability to survive from the natural or man-made hazards. Hence, urban resiliency to disasters can be achieved more efficiently through the means of improving the “smartness” of the cities.

Smart cities are not about making huge investments in infrastructure building, but about making infrastructure do more and last longer while aiming to reduce negative environmental impact (Bansal et al., 2017). Therefore, the smart city is one that uses technology, data, and intelligent design to enhance the livability, workability, sustainability, and resilience of cities (Stasinopoulos & Chalaris, 2020). Smart cities should be resilient in all stages of a disaster cycle, pre-disaster stage, disaster stage, and post-disaster stage, so they have various kinds of strategies and techniques. As per DesRoches and Taylor (2018), smart technologies and systems can strengthen disaster monitoring and risk assessment, so better predictions and preparations can be done. They can quickly respond to citizen concerns by monitoring infrastructure and environments in crisis and addressing associated safety issues. Finally, rapid restoration of critical city services can be ensured.

Authors have discussed the same phenomenon using the word “urban safety.” Urban safety expects to enhance the resilience of cities, such as improving the ability to recover from shocks, disruptions, disasters, and crises (Helbing et al., 2021). The term disaster resilience is strongly affected by the smartness and safety of city systems; hence, to originate high resilience within the city, all systems must work with high efficiency, and there needs to be a connection between each system (Bansal et al., 2017). Also, researchers have highlighted the importance of information and communications technology in enhancing disaster resilience. As literature mentions, ICT can be used as a means of getting the involvement of people, improving the services rendered by the city, and enhancing the urban systems are making definite improvements in disaster resilience (Bansal et al., 2017). In addition to that, previous literature explores the ability to stimulate the learning process and strengthen urban resilience against disaster risk by exploiting the transformative power of information and communications technology (Vermiglio et al., 2020).

Therefore, the current study highlights the importance of giving more priority to the “disaster resilience aspect” when defining the term smart city. If the cities are resilient, they should be necessarily livable, workable, sustainable, and resilient. Therefore, the authors suggest that these aspects should reflect through the definitions of “smart cities” along with other elements (see Fig. 1).

The Importance of Incorporating the “Ethical Aspect” When Defining the Term

Any standard of the advanced city could be destroyable due to unethical human actions that are being experienced by contemporary society. Yet, many studies are silent about the ethical aspect or smart values that are essential to maintaining a smart city. Only a few authors and practitioners have discussed this ethical aspect of smart city literature. Cobbe and Morison (2019) have stated that the ethical aspect has been

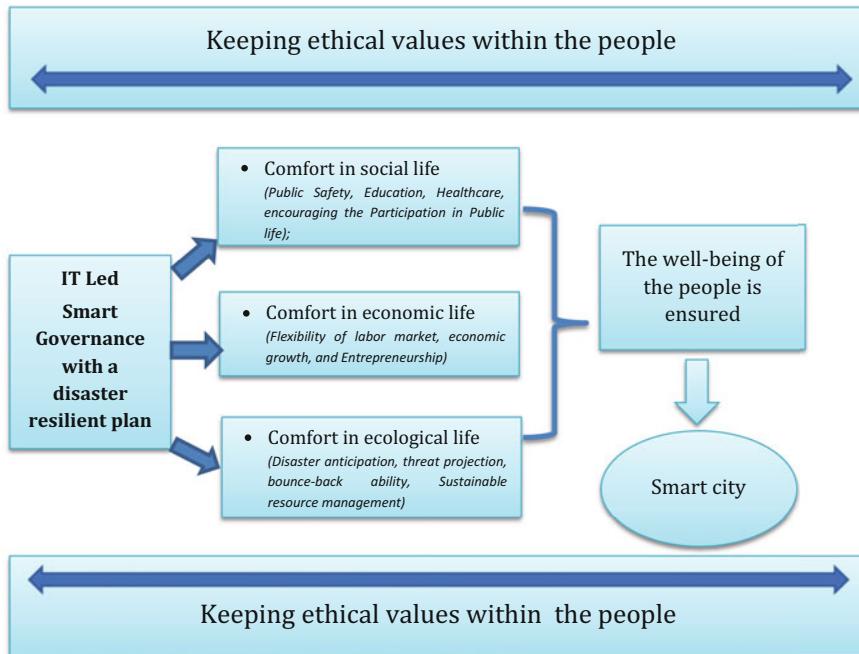

Fig. 1 A framework for specifying the meaning of the “smart city” concept

missed in this hungry journey of city leaders to achieve “smart” status for their cities. According to them, especially, smart values like fairness, transparency, agency, and accountability should be associated with smart city technologies. As noted by Albert (2020), smart city solutions are working, when they address the ethical dilemmas inherent in these services. Singh (2019) noted that technology is the mere scaffolding that lifts the structures of society and cities cannot be built from technology up; they should be built around the needs and values of the human. Some authors have discussed the ethical issues which could emerge due to smart cities and the necessity of having smart values to overcome those issues. For instance, unequal citizen inclusion and the privacy threat due to mass surveillance are identified as issues of smart cities (Cobbe & Morison, 2019). Since the smart city technologies trace every move, habit, medical problem, and other private details of its people, it jeopardizes their liberty. Therefore, data transparency and privacy should be the top priority of the smart value system of its leaders. Accordingly, there is now an emerging debate between smart cities and ethical cities among scholars.

Indeed, when there is absence of ethical values among the people, all that physical, technological, and intellectual designs would not work properly. All those sophisticated city developments can be suddenly destroyed by a single action of an unethical person in the city. Therefore, the current study identifies the “smart values/ethics” of the people as a novel dimension of smart cities. It has been

considered the outer layer of the successful smart city, which ensures the smooth functioning of the entire system (see Fig. 1). As a concluding point to the discussion, the following figure specifies the meaning of the smart city concept.

Accordingly, the concept of a smart city could be broadly considered as a city with IT-led smart governance that ensures the comfort of the social aspect (public safety, education, healthcare, encouraging the participation in public life), economic aspect (flexibility of labor market, economic growth, and entrepreneurship), and environmental aspect (environment, sustainable resource management) of people's lives, through IT-led infrastructure, and ultimately improves the quality of life and well-being of the people in that city. More importantly, this entire system functions properly in an environment where people have ethical values.

When congesting the above idea more narrowly and preciously, "a city is said to be smart when it economically, socially, and environmentally enhances the well-being of its citizens through the smart governance which is blended with intellect, creative, and hi-tech solutions, a disaster resilience plan, and ethical values of the people."

Conclusion

The fuzziness of the existing literature made the researchers enhance the meaning of the smart city concept. Smart governance is an effective and efficient government which is a prerequisite of a smart city. The presence of smart governance is important as the regulating body making the right policy choices and executing them in a productive manner. ICT plays a facilitating role in every aspect of smart cities. The creation of ICT-led infrastructure is important for governments to act smartly, through the enrichment of services like public safety, public utility services, environment safety, sustainable resource management, entrepreneurship, flexibility of labor market, and economic growth. When those elements are properly functioning, the city becomes more resilient to man-made or natural disasters. Specifically, the city will be more capable of predicting and minimizing threats, absorbing damage, and bouncing back soon. Hence, finally, the "well-being of people" and "the quality of life" would be enhanced. However, all those sophisticated city developments could be suddenly destroyed by a single action of an unethical person in that city. Thus, the current study highlights the importance of identifying the "ethical values of people" as a vital dimension in defining smart cities. Therefore, it can be concluded that the inclusion of disaster-resilient aspects and ethical aspects into the characterizations of a "smart city" will enhance the smartness of the concept.

Abstract

Mankind is currently encountering increased urbanization. The world is moving much faster with ease of access to anything and everything toward a status called *smart*. India, a diverse nation, is one of the fast developing countries in the world. The continuous achievement through computer literacy in popular fields especially in Information and Communications Technology (ICT) has motivated the country to plan for smart city development. However, the concept of smart city aims for a luxurious development which is going to be more computer competency and expensive. The concept of smart cities tends to provide technological advantage to its population, but it is imperative to look its effect on certain segments of the society, especially the underprivileged in terms of their

accessibility and affordability. Moreover, the understanding of the concept of smart city development has made the researchers to think aloud the possible factors of providing resilience and sustainable development for the underprivileged eradicating discrimination, inequality, and injustice. Therefore, the main objective of this conceptual chapter is to glean ideas and suggestions regarding resilient, inclusive, and sustainable smart city development. This chapter will explore, through statistical information, models and best practices for disaster-resilient smart cities for the underprivileged.

Keywords

Smart city · Urbanization · Underprivileged · Computer competency · Sustainable development

Introduction

“Smart cities” is a popular terminology used in the worldwide developmental process. The perception of the term *smart* toward the people is an application of the technologies for the ease of access to luxurious deluxe lifestyle. The world’s future key element for growth and luxury lies in the construction and existence of city customs (UNFPA, 2012) that have published a report stating that more than 50% of the people which constitutes 3.3 billion of the world’s population lives in the urban areas and are expected to increase by 70% in 2050. The enlargement and implementation of Information and Communications Technology (ICT) has a plan for worldly modification with sustainable development (Albino et al., 2015). According to the Human Development Index (HDI) report for 188 countries, India ranks 131st with an evidence of world’s leading number of population in which 642 million are living in poverty and over 800 million people are still living in rural areas (69%) (UNDP, 2016). The mission for smart cities in India has an inception from the month of June 2015 which aims to create 100 smart cities on tenure of 5 years by 2020. By considering the current conditions, the period has now been extended to 2023 (HLRN, 2017).

In the mid-twentieth century, plentiful environmental, social, economical, and political crisis has affected our society on a larger scale (Trindade et al., 2017a). Many countries have strategically tackled and have moved its society toward sustainable (Toh, 2022) development. Later the development methods of the twenty-first century had focused particularly on Information and Communications Technology (ICT) (Gere, 2019) establishing a trend of moving toward global smartness which is believed to make the human life more comfortable in all aspects (Corcuera et al., 2019). Smart city is not a new concept for many developed and developing nations, but globally, there are still many countries that face challenges in understanding the concept clearly (Gade, 2021). Even today, many international countries misunderstand the exact ideology of smart cities limiting itself only to technological advancement (Samih, 2019). However, the concept of smart city

includes a planned infrastructure, renewable energy sources, Information and Communications Technology, Internet of things, sustainability (Mohanty et al., 2017), and most importantly disaster resilience (Parker, 2020).

Disaster is a growing menace for sustainable development (Keating et al., 2019). With increased universal risk, it should be dealt with development objectives. Resilience is an important terminology used in the area of disaster risk management (DRM) (MacAskill & Guthrie, 2014), but nowadays, resilience has been threatened by poor sustainability; therefore, it is moving toward implementing and establishing ideas for sustainable development (Toh, 2022). At the present time, this concept is playing a key role in the international, national, and local policy and development (Parker, 2020). Therefore, resilience against man-made and natural hazards is paramount for the well-being of many modern societies (Marasco et al., 2022). Hence, disaster resilience on a whole covers various aspects relating to vulnerability, governance, risk, sustainability, and adaptation (Parsons et al., 2016) which arrest the underlying drives for global risk. There exist critical research gaps for the underprivileged population regarding disaster preparedness (Shih et al., 2018) as the population need to be harnessed to strengthen the resilience building activities' inclusiveness which helps to manage and inculcate ideas regarding active disaster preparedness within the underprivileged population groups (Acosta et al., 2018). Therefore, by reviewing extensive possible literatures and government reports, this chapter seeks ideologies to include the underprivileged sections of the society and have possible amenities provided to ensure the best livable conditions among the urban population with the aid from technological innovation (Annual Report 2017–2018). The specific objective of this study is to analyze social inclusiveness for the underprivileged. Before analyzing, there are some significant concepts which suit for the study area to understand these concepts in a clear-cut manner and inculcate the readers with clarity in a broader sense.

Development of Smart City

The term smart cities had been introduced in the late 1990s by the European and the American countries as their focus was on innovation and invention, which made them far advance among nations worldwide (Simpson, 2015). The invention of computers, the Internet, and electronic devices which can store and retrieve data has made the world to think ahead towards being smart. At the same time, the concept of smart cities is still a dream for many underdeveloped and developing nations as it demands for huge economic and technological investment in terms of luxury and development (National League of Cities, 2016). Smart cities aims toward a “systems of people interacting with and using flows of energy, materials, services and financing to catalyze sustainable economic development, resilience, and high quality of life; these flows and interactions become smart through making strategic use of information and communication infrastructure and services in a process of transparent urban planning and management that is responsive to the social and economic needs of society” (Sherpa Group and the Stakeholder Platform, 2013).

The concept of smart cities was introduced in-between the years from 2014 to 2015 by the government of India. Globally, India being a developing nation, the industrialization and the technological innovation during post-independence has made India to flourish in developing the rural areas into urban areas which has completely changed the lifestyle of the country (HLRN, 2017). As a result, the Indian population has been classified into many segments from the rural, urban, and metropolitan and now into smart. India has planned to implement the necessary steps for realizing smart cities covering 100 selected cities nationwide in 2015, and the vision statement of the government of India's smart city program to "improve the quality of life of people and attract investors to invest to establish a virtuous cycle of growth and development" using the strategy plan of retrofitting, redevelopment, greenfields, and pan city, thereby quickly moving toward achieving the vision. The Indian government has also defined the concept of smart cities as "Developing the entire urban ecosystem which is represented by four pillars of comprehensive development – institutional, physical, social and economic infrastructure" and "Smart Cities are those cities which have smart (intelligent) physical, social, institutional and economic infrastructure while ensuring centrality of citizens in a sustainable environment" (Wadhwa, 2017).

Disaster Resilience: An Overview

Over the past decades, research studies on resilience have become a hot topic in many areas of scientific and applied research and also in multi- and transdisciplinary research context (Fan & Lyu, 2021). The term resilience has its own long and diverse history and has evolved from the concepts of "build back better" to "bounce forward" (Graveline & Germain, 2022). Disaster resilience can be justified as the ability to recover, emerge stronger, and overall withstand future unpleasant events (Acosta et al., 2018) that seriously threaten people's lives (Nurhidayati et al., 2020) irrespective of any geographical location worldwide. Globally, natural and human-made disasters are threatening factors of the rural and urban development (Xu et al., 2021). Urbanization has become an irreversible procedure and an indicator of national economic development and poverty diminution.

India may be said to be in the midst of evaluation from rural to quasi-urban society (Bhattacharya & Rathi, 2015). According to a census report, 52 Indian cities had more than a million population, and over the years, the urban population has increased and still keeps on increasing (Census 2011). Thus, smart city project mission aims to boost the economic growth and enable a standardized decent quality of life for the people and address problems through smart solutions ultimately ensuring human growth and development (Annual Report 2017–2018). In addition, the mission proposes the concept of resilience, with the main objective of reducing risk and enhancing resilience in all stages of a disaster by promoting smart connections toward vulnerability and sustainability development (Xu et al., 2021).

Smart City Mission: A New Developmental Context

India has an urban population of 410 million, making it the second largest urban nation in the world. The cities contribute 31% of India's population which constitutes 63% of gross domestic product (GDP) (Census 2011). In the past, the government of India and its union states and territories have faced many challenges in the urban improvement. New initiatives like "Make in India" project and "Clean India Campaign" have moved the country for a sustainable and inclusive development. The development has initiated the government to create new and improved cities for the nation. Private firms have also extended their roles in establishing new urban development projects like Lavasa and Palava which are located in the state of Maharashtra (Ministry of Housing and Urban Affairs, Government of India, 2019). Subsequently, the country has also planned for collaborative development through assistance from the world nations. One such program includes turning Varanasi into a smart city with the collaboration support from Japan, and even the United States has also shown interest in tie-up development. Like all the governments of the world, India also focuses on the need to provide new modernized infrastructure and advancement in the public sector (HLRN, 2017). Even though all these works are being witnessed in the mission of smart cities, the underprivileged of the country still lives in extreme poverty, and citizens basic rights are still not fulfilled and their representation has not been accepted as the living standard and the business which they perform has a negative impact in the urban services (Handbook of Urban Statistics, 2019).

Need for Disaster Resilience in Smart Cities

Disaster is an intensified damage which can be natural or man-made. It is recorded that the 3751 natural disasters which include earthquake, flood, tsunami, etc. have occurred globally for the past 10 years and have affected 1658 billion people (International Federation of Red Cross and Red Crescent Society, 2018). Disaster management is a prearranged structured activity that a strategy plan of action is required to manage the disaster efficiently. Disaster management and resilience needs an effective environment that enhances the initiative performance in developing smart cities. The disaster-experienced citizens are forced to live in poverty as they are vulnerable and their needs cannot be addressed continuously. Some studies have found that people with lower income and who are poor are in greater risk when they are exposed to natural and technological disaster (Eggers & Skowron, 2018). The disaster impacts are also becoming more critical and the crisis after the disaster becomes comparatively high. The post-disaster problems are more pathetic as the population especially the underprivileged lack housing, security, and resources and have a tendency to develop physical- and mental health-related problems (SAMHSA, 2017). The concept of smart city also aims to predict disaster prior to its usage of the latest technology, i.e., Information and Communications Technology (ICT), in response, rescue, and preparedness phase of a disaster. The invention of

smart gadgets and technological advancement like social media, smart phones, location-based system, satellites, sensors, etc. will potentially function for creating a new era and will provide intimation toward disaster management system in prior (Shah et al., 2019). The tragedy of post-disaster sweeps the entire development of the country and pushes the country to start from the initial point once again, but a disaster-resilient system with the smart technological conditions helps toward re-accumulation of resources and makes the country overcome the crisis situation within a short span of time. Smart development and resilience are closely related to each other in terms of growth, urbanization, and development.

The concept of smart city planning must not be a disaster mission but a resilient mission; hence, this undertaking should be strategically planned toward self-recovery from the hazards, traumas, and crises which ensure better sustainability for the countries' growth. Resilience on the other hand is more important for the nation as it prepares a post- and pre-successful plan for the speedy development and avoids the risk approaching multidimensional (The High-Level Political Forum on Sustainable Development, 2017). Improvement of disaster risk management inculcates awareness and helps to plan a nation with more sustainability in development, inclusive of all the contributors of the national development. The understanding of disaster resilience balances the areas in need of development in addressing and improvising the needs of the vast section of the society (Korngold et al., 2017). A resilience development should take in sustainable policy and practices with professional risk management practices and develop a framework with potentiality and consistency.

Smart city should ensure the use of ICT to its fullest and heighten the level of consciousness through which the citizen's intelligence, well-being, community participation, hazard handling, crisis intervention, trauma recovery, etc. get saturated. The inculcation of the rights and responsibilities for transformation of sustainable development achieves quality of life for the underprivileged section of the society (Skouby et al., 2014). With such improvement in technology, the government of India has initiated a plan of smart city for the national improvement with a vision to compete with the developed nations.

Disaster Preparedness and Challenges in Indian Smart City Context

The Disaster Management Act, 2005, defines disaster as "The catastrophe, mishap, calamity or grave occurrence in any area arising from natural or manmade cause, or by accident or negligence which results in substantial loss of life of human suffering or damage to, and destruction of property, or damage to, or degradation of environment, and is of such a nature or magnitude as to be beyond the coping capacity of the community of the affected area" (Ministry of Corporate Affairs, 2017). In India, the National Disaster Management Authority (NDMA) is the government nodal agency that is working exclusively in laying down policies for disaster management. NDMA was created by enacting the Disaster Management Act on December 23, 2005.

NDMA is headed by the Prime Minister and the State Disaster Management Authorities (SDMAs) by the Chief Minister of the respective states and union territories. Other organizations which work for disaster management and preparedness are the National Institute of Disaster Management (NIDM) and National Disaster Response Force (NDRF) (Thattai et al., 2017). These organizations work toward disaster preparedness, rescue, relief, rehabilitation, capacity building, and mitigation (Sharma, 2021) which helps to create field awareness and strategic response plans toward disaster management. India, with increasing unplanned urbanization, has poorly planned and unmanageable urban development. Smart cities in India aim to create an urban space where green, hi-tech initiatives create much efficient utilization and management of resources like water and energy and better services to the community (Magotra et al., 2019). Therefore, obtaining a fully efficient protocol toward disaster management and smart cities is highly challenging, but it can be improvised through continuous monitoring and updating of the global ideas to help prevent massive exposure to disaster (Elvas et al., 2021).

Smart City: An Inclusive Ideology

The smart city mission as a national development program ensures full development of all sections of the society; above all it should not posit the underprivileged section of the society to stay behind in darker side which directly affects the nation's development (OECD, 2015)). The urban India comprises majority of the people living in the slum and in unhygienic condition. Their contribution to the national development is also to be respected and recognized as they too have equal rights to be exercised (Haughton & Khandker, 2009) and should be allowed to experience and enjoy the nation's development without any discrimination. Smart city, a planned project of the nation, is showing progress towards creating sustainable environment with representation from all sections of society. Irrespective of huge population parameters, the underprivileged and the weaker section of the society has no constructive representation within themselves (Phadke, 2018); thus, negotiation with them will be a struggle and ensuring full development is a question.

The awareness to differentiate the cause for development is only possible with education as the questioning tendency becomes reasonable when literacy is ensured. The government along with the bureaucracy should ensure enough transparency to educate the underprivileged on their rights and must ensure their sustainability in their developmental standards (Trindade et al., 2017a). The growth of the nation should promote developmental space for the underprivileged with equal and sustainable distribution to all; therefore, the citizens of India must make sure for a unified development witnessing “India, a nation unified with diversity.”

Underprivileged Urban: Plan Smart with Sustainability for All

India is a fast growing urban country. According to the 2011 census, the urban population has increased to 377.1 million compared to the 2001 census which was 286.1 million. In the recent years, India has developed a large number of newly emerged towns which shows there is a huge industrial investment and demand for urbanization. Expansion in urbanization created in encroachment of urban slum which remains as a hindrance in country's development. Access to basic amenities like employment, transportation, sanitation, housing, and livelihood has also improved in a good number which is recorded in the 2011 census (Ministry of Housing and Urban Affairs, Government of India, 2019). Literacy rate as one of the indicators of the society's development records that the urban overall literacy population was 84.1%, and Mizoram and Kerala states have high literacy rates of 97.6% and 97.1%, respectively. In low human development countries, the adult literacy is 47.5% in total and the population which has access to the Internet is 17.1% (Registrar General & Census Commissioner, India 2011). Even though the country has developed in various aspects, the swell in the urban population has created slum development leading to vast and congested people's settlements, and thus evaluating these aspects, the underprivileged society of India stands as a hindrance in the development of urban infrastructure.

The Planning Commission (2013) articulates vision for "faster, more inclusive, and sustainable growth." The plan emphasizes five agendas which include (1) inclusiveness as poverty reduction, (2) inclusiveness as group equality, (3) inclusiveness as regional balance, (4) inclusiveness and inequality, and (5) inclusiveness as empowerment. The five agendas were initiated to promote sustainability and inclusiveness which decides the countries' development (World Economic Forum, 2015). The Sustainable Development Goals by the United Nations especially the first, second, third, fifth, and ninth goals have been widely focusing on the development of underprivileged (The High-Level Political Forum on Sustainable Development, 2017).

There are four fundamental truth which serve as a foundation for the system of successful implementation and execution of smart cities for the underprivileged. They are the following: "(1) wellbeing, this includes safety, infrastructure, and functionality to enhance the overall performance from the citizens' perspective; (2) equity, this focuses on the accessibility and coverage for the poor and marginalized in which the well-being condition is available to all the section of the society without any discrimination; (3) efficiency, this focuses on the performance of the individual and the country with the utilization of the resources, finance, and human power; for a better and expected outcome, the quality is ensured and the resources on all aspects are highly utilized; and (4) foresight, the long-term achievement is analyzed and the aspiration and the strategy that needs to be attained are planned strategically" (Bhattacharya & Rathi, 2015).

Smart City: A Representation for the Underprivileged

Metropolitan areas have engaged in the development of urban infrastructure. Sustainable urban development inculcates people regarding the awareness to limit the uses of resources by reusing it to the fullest. This chapter proposes four attributes for achieving smart and sustainable city: (1) sustainability, (2) quality of life, (3) urban aspects, and (4) intelligence. These four attributes enhance innovation and problem-free practices for the underprivileged and weaker sections (Trindade et al., 2017a). Simultaneously, there exist many models and practices worldwide but their successful implementation is still a question. The factors of development in the country have created an imbalanced pattern in the living standards of people. Planning a smart city for all the sections of the society in the short span of time tends to develop bias and stereotype with weaker section of the society which leads to political unrest and problem in social development (Phadke, 2018). However, the population of the underprivileged is high and they are harassed, humiliated, and discriminated because they are powerless and lack social representation (Plotnikov et al., 2019). Planning smart cities with the inclusive representation equally benefits to address their needs and the representative's voices are recognized.

Lack of infrastructure and improper planning of cities result in population explosion. Thus, the underprivileged people in the long run will establish temporary shelters which in the long period of time will develop into slum settlements in the urban areas (Phadke, 2018). It is difficult for the government and the administrators to eradicate existing slums in a shorter span of time; rather, identification of emerging new slum can soon be addressed and can be stopped with establishing new settlements through slum clearance board. The underprivileged and the weaker section of the society are forced to stay in the urban areas as the opportunity for the employment is high compared to the rural areas (National Disaster Management Plan, 2016); thus, the new smart city mission should ensure equal distribution of employment even in the semiurban areas.

Through the urban development, the smart city mission should guarantee sustainability in development by creating more space for the migrants and the underprivileged. The people should be unified and there should be also representation from the underprivileged to ensure inclusion and equality in sharing resources and thereby to have unified development for sustainability growth (Plotnikov et al., 2019) which unites them for a better adaptation with others in the developmental context of smart cities.

Social Inclusion for Underprivileged

Social inclusion and exclusion are inseparable sides of the same coin, and every person has a mind-set to live in prosperity and enjoy a good standard of living. The sustainable development models aim to evacuate all the society from poverty and hunger and provide access to health education and information (Trindade et al., 2017a). Social inclusion is a process and a goal to be achieved in all aspects of

development promoting and helping in eradication of exclusions of the society. The socially excluded groups according to this study include poor, uncared elderly, urban slum people, and disabled. Social inclusion aims to have a full-fledged participation of all the excluded groups ensuring growth and development by providing opportunities for their involvement and respecting their rights through nonbiased distribution of the resources (National League of Cities, 2016). Discrimination is the major hindrance for inclusiveness as it motivates exclusion process leading to injustice and obstructs the even distribution of opportunities triggering discouragement and isolation. The underprivileged mentioned in this study due to their incompetence and exclusion from the dominant society finds some hardships to compete with them as their state of exclusion has made them to extend on dependency which leads to personification. The exclusion has prolonged through many ideologies in the human era which extends toward unequal access to resources, unequal participation, and denial of opportunities which suppressed their growth for development.

Old age is an increasing phenomenon and the elderly are considered to be the most underprivileged section. As the world's majority of population is growing old creating dependency, excluding them in terms of their age leads to discrimination; thus, the elderly should be taken cared of with proper infrastructure and ensuring their rights and privileges. The twenty-first-century social contract for urban life must be rooted in an age-friendly philosophy, making the elderly feel safe and secured (MHFI, 2016). Infrastructure development, housing, access to community health opportunities for education, recreation, etc. should be included in the provision of smart city mission. Age-friendly city should be constructed for a better user-friendliness for the older people to satisfy their changing needs (Skouby et al., 2014). With the application of universal models, smart city development may heighten the level of awareness for a successful planned city with inclusion of all the section of the society.

Access and Affordability for All

Any swift change is difficult to accept as this is an existing human psychological inclination. India's smart city concept has made some turbulence among the social scientists and thinkers as the sudden implementation on a shorter span of time may lead to subjective issues like gender inequality and discrimination toward women, minorities, schedule cast, schedule tribe, children, person with disabilities, and also to the poor and slum living people (World Economic Forum, 2015). To have a clear outfit on the above said issues, a question was put forth by the opposition party on the house of the people, i.e., Lok Sabha, "Question: Whether the Government has taken into consideration people with special needs, the aged citizens, and such special classes of citizens, to ensure accessibility in the smart cities and if so, the details thereof." To this question by the opposition, the response was given by the Minister of Housing and Urban Affairs "Answer: The Smart Cities Mission aims at accelerating economic growth and improving the quality of life of people, among others, the core infrastructures elements in Smart Cities also include affordable

housing especially for poor, and safety and security of citizens, particularly women, children and elderly provision of accessibility infrastructure has also been made in the Smart City Proposal prepared by Smart Cities” (Lok Sabha, Question No. 1075, 8 February 2017). Hence the concept proposes for an inclusion in every section of the population, thereby ensuring access and affordability leading towards consistency in growth and development (HLRN, 2017).

Disaster Preparedness for Underprivileged: Universal Model

Prevention is a safe game played by many external and internal contributors in which they establish a model of change for the future world. Some universal initiatives taken by the world nations have to be acknowledged especially for the underprivileged because as citizens, their lives also matter. The Californian government incorporates solutions like the individual-resilient solution and community-resilient solution to generate awareness and assistance among all sections of society (Cal OES, 2019). The Indonesian government in Jakarta (capital of Indonesia) has initiated an innovative early warning system via SMS at the urban slums alerting people on upcoming floods, and large-scale adaptation infrastructure projects have also been developed to accommodate the urban slum people during urgent floods. Sao Paulo, a municipality in Brazil, identifies risky areas for landslides via geo-referencing and alerting people of the slums in prior and efforts for landslide major slum upgradation are always ensured (Baker, 2012). Toyama city in Japan uses walking assistance cart (a four-wheel walking aid) for elderly safe transportation during normal and disaster situation (OECD, 2015). These models exist as some key eye-openers for the world nations acknowledged from the perspective of the underprivileged which are in similarity and can be incorporated as a universal model for the Indian government in terms of smart city development. Hence, by incorporating these ideologies and moving forward the disaster resilience smart cities will be a successful proposal benefiting all the section of the society ensuring social inclusiveness with special reference to the underprivileged.

Disaster Preparedness for Underprivileged: Indian Model

India’s geoclimatic condition and high degree of socioeconomic vulnerability have made the country disaster-prone among the world’s nations. During the last 30 years, the country has been experiencing nearly 431 major disasters which have led to loss of many lives and properties. Most of the disasters occurring in India are floods, cyclones, windstorms, heat waves, earthquakes, landslides, etc., and based on intensity, these disasters are classified into moderate, high, and severe risk (Magotra et al., 2019). The concept of disaster management has been chaptered in detail by the Tenth Five-Year Plan (Kaul et al., 2016). Disaster preparedness for the underprivileged in India begins from legislative and institutional framework under the Disaster Management Act of 2005, National Policy of Disaster Management, and state

legislative acts enacted prior to disaster management act, legal institutional framework for disaster management, and response setup across the country for disaster management. The legislative framework has been screened and planned by the national plan for disaster management, state plan for disaster management, national disaster management guidelines, and demarcation of roles and responsibilities. Therefore, based on the funding and resources arrangement, the plan will be executed by the National Disaster Management Authority by communication and response system (Union Government Civil, 2013). Hence, by assessing the vulnerability, the response team seeks for effective evacuation process through the application of community-based disaster management strategy (Bhagath, 2020; Singh, 2013). Thus, to address the underprivileged, the national disaster frameworks which include institutional mechanism, early warning system, disaster preparedness and mitigation, disaster prevention strategy, and human resource development (Subbaraju & Siva Krishna Raju, 2015) are continuously monitoring and working with the national broad guideline for the betterment of the underprivileged Indian population.

Conclusion

The smart city mission creates more opportunity for humanity to move toward holistic and inclusive development. The application of inclusive development ensures the underprivileged to participate in establishing smart city project. Inclusion as an instrument imbibes human rights and eliminates social exclusion. The government of India on execution of the project needs to be more specific in adapting the benefits for the underprivileged on a multidimensional approach for a sustainable developed nation. Technological development should not be a barrier or an obstacle as the upcoming generation and the mid-aged population shall be informed on technological utilization and a proper assistance shall be ensured for their comfortableness. Hence, the ideology of implementing smart city mission in various cities will be a success when all the populations are given inclusive equal opportunities, by which people of all segments get benefited which obviously benefits the development of the nation.

Abstract

The chapter is an attempt to address the issues of disaster governance and public policy in Dhaka, the capital of Bangladesh, which is a designated smart city. A smart city is recognized as environmentally secured, safe from disaster risks, and has efficient governance for living and livelihoods. A smart city ensures integrated products and services, creation of jobs, wise use of resources to develop the living standards of city dwellers. Owing to national policy and economic resource strategy Dhaka has emerged as a center of livelihood for people from across the country. Having more than 20 million people, Dhaka city contributes to 36% of the country's GDP. The high density of people and property in Dhaka city compound the risk for natural and/or technological disasters. Flood, water logging, drainage congestion, un-planned use and abuse of wetland, earthquake, pollution, and fire are the potential disaster risks and challenges faced by Dhaka, which is constantly increasing its rapid expansion. However, in terms of policy, planning, and program formulation and implementation the Dhaka city governance authorities with institutional arrangements are facing the challenges of disaster mitigation with knowledge and capacity. Now it needs coordinated efforts of government organizations, nongovernmental organizations, Civil Society, Researchers, Scientists, Media, and city dwellers to provide an effective response to the mitigation approach to achieve good disaster governance in building Dhaka as acceptable among the smart cities of the developed world.

Introduction

Dhaka city is no stranger to disasters, but is recognized as one of the most vulnerable cities to the impacts of natural as well as manmade disasters such as flood, water logging, drainage congestion, unplanned use and abuse of wetland, pollution, fire, and the potential risk for earthquake. Dhaka is situated on the southern fringes of an area that is seldom flooded. Dhaka city has experienced many major floods affecting up to 77% of the area, with about 66% of city dwellers being submerged. Wetlands are described as a natural security in maintaining the environment. Owing to rapid expansion of housing, industrialization, and infrastructural development, the wetland of Dhaka city and its adjacent area are being reduced, thus affecting the natural drainage system and causing frequent water congestion and water logging with adverse effects on the surrounding ecology and biodiversity. Hazards such as fires and technological disasters occur in Dhaka city almost every year, causing a huge loss of lives and assets, which has led to disruption of living conditions of city dwellers. Increased population, faulty electrical wires, higher power loads, loose connections, use of old equipment, unsafe use of chemicals, old and risky gas pipelines, and petrol and compressed natural gas (CNG)/liquefied petroleum gas (LPG) stations have been linked to the increasing frequency of fires in Dhaka city. Environmental problems created by the transport sector and pollution generated by defective fuel burning from motor vehicles constitute one of the major health hazards and cause road congestion in Dhaka city. Experts indicate the possibility of an impending earthquake striking Bangladesh any time in the future; if this happens, there will be a mega-catastrophe in Dhaka city with unbelievable damage to the infrastructure, property, and loss of life. Against this backdrop, the future development of Dhaka to build as a smarter city are being guided by the national policy makers and related public institutions taking account of disasters and their effect.

Dhaka, the capital city of Bangladesh, has existed for many hundreds of years as physical urban. Dhaka is situated on the banks of the river Buriganga and at a center point between the Bay of Bengal and the interior region of the country. In 1960, the Mughal Emperor centered their provincial capital of Bengal in Dhaka. Over the last 400 years the size and population of Dhaka city have increased remarkably. Once Dhaka was planned for 1 million people (Mitra & Ali, 2009). At present more than 20 million people live in Dhaka, which is about 10% of the country's total population. The population of Dhaka city is growing continuously either by birth or by migration. Dhaka alone contributes 36% of the country's GDP (World Bank, 2012). Owing to national policy and economic resource strategy Dhaka has emerged as a center of livelihood for migrants including job seekers and emerging elites from across the country and has now shaped the hope of alternative income opportunities, education, health care, and substantial improvement in livelihood. The average share

of employment in Dhaka is 51%, i.e., 14% in the public sector and 37% in the private sector, and 20% of the working population is engaged in industries (IGS-BRAC, 2012). From the inception, the focus of investment and construction prevails in Dhaka city; most industries, manufacturing units and readymade garment (RMG) factories are located and constructed in Dhaka city. The RMG industry accounts for half of the formal employment of the country and 30% of the RMG jobs are located in Dhaka city. The industry and wealth of Dhaka city has been based on flood plains, which have sometimes been a victim of disasters. When disasters happen the livability of city dwellers has to be compromised and governance is seen to be the influential factor in improving the livability and making them resilient.

The high density of people and property in Dhaka City compound the risk for natural and/or technological disasters. By disasters are meant here all those that cause hazards to the day-to-day affairs of Dhaka City, disrupting wellbeing and the livability of city dwellers and polluting and degrading the environment. Owing to the concentration of built structures, infrastructure, properties, and people, governing disasters in Dhaka is a very complex task. Governance is defined in terms of policy, planning, and program formulation and implementation with knowledge, capacity, transparency and accountability; and institutional arrangements for facing disaster hazards. Thus, in building Dhaka as a smart city the challenge of disaster governance and policing is equally as important, such as financial mobilization, infrastructure, and information and communications technology (ICT).

Disasters, Policies, Governance, and Analysis

Flood, water logging, drainage congestion, unplanned use and abuse of wetland, earthquake, pollution and fire are the potential disasters risks and challenges faced by Dhaka, in its path to developing into a smart city, which is constantly increasing with its rapid expansion. To ease the situation in 1989, a Flood Action Plan (FAP) was formulated to protect Dhaka City with the objective of providing flood mitigation, drainage improvement, and a safe living environment for city dwellers. In this respect, other major initiatives that have been taken so far are the Flood Hydrology Study, Flood Management Study, National Water Plan, National Water Policy, and the Flood Warning System Study. Wetlands in Dhaka are reducing because of the rapid infrastructural expansion of Dhaka. To address this hazard, the Wetland Conservation Act-2000 and the Detailed Area Plan were issued to protect the wetland of Dhaka; Water Supply and Sewage Authority Act 1996, Bangladesh Environment Protection act-1995 to deal with the pollution of water bodies and the Water Bodies Protection Act-2000 for the rational use of water bodies for housing and infrastructural development. As precautionary policy measures toward an impending earthquake to strike Bangladesh in the future, there are Bangladesh National Building Code, 1993 and Dhaka Metropolitan Building Construction Rules, 2006 to cover planning administration and enforcement, general building controls and regulations for earthquake safety and fire protection. In order to face the post-earthquake situation Bangladesh government has taken initiatives to form a

group of volunteers, procure equipment for search and rescue-related operations, and has a plan for disaster-related equipment. Fire events are far from being accidents and are preventable. Factory fires happen because of poor planning and a weak infrastructure. Factories Rules 1979, Fire Prevention and Extinguishing Rules 2003, Bangladesh National Building Code 1993, and Dhaka Metropolitan Building Construction Rules 2006 provide broad guidelines on fighting fires, evacuation systems, and directives for making buildings relatively safe from fire hazards. Every year in April Bangladesh Fire Service and Civil Defense observes fire prevention week for awareness building. The Government has enacted Transport Policy 2019 to tackle the situation. However, there are plans and programs for disaster governance for Dhaka to make a smart city but it is also a fact that the city has largely grown in an unplanned manner, thus making it vulnerable during disaster. The Bangladesh Water Development Board, Bangladesh Fire Service and Civil Defense, RAJUK (Capital Development Authority), Bangladesh Road Transport Authority, and Dhaka City Corporations are the vital agencies on disaster mitigation initiatives that led to the development of policies and proper monitoring to control and enforce policy/rules for Dhaka city being smart. In 2010 the Government issued a National Plan for Disaster Management involving the governance of risk and consequences of disasters and formed a separate Ministry of Disaster Management and Relief as a key point on disaster governance.

A smart city is not just about technology, but also about an urban center that is safe from disaster risks, environmentally secured, and has efficient governance for living and livelihoods. A smart city ensures integrated products and services, smart solutions to infrastructure, and promotes a variety of transport options; a smart city can create jobs, use resources wisely, and develop people's living standards. Almost 60% of people across the globe live in cities that are at risk from at least one major natural disaster such as flood, drought, cyclone, or earthquake. Owing to climate change the frequency and intensity of these disaster events are thought to have greater risk and vulnerability. Bangladesh is recognized as one of the most vulnerable countries to natural disasters owing to its geographical location and high density of population. In the context of Dhaka City, disasters and hazards are posed by floods, water logging, drainage congestion, unplanned use and abuse of wetland, earthquake, pollution, unauthorized infrastructure, and fire. In Dhaka City, so many buildings exist close together and millions of people live in close proximity, which brings some issues when natural disasters arise. Thus, adaptation of policies and governance is a justified concern for minimizing and reducing the vulnerability of the city dwellers.

Dhaka city has experienced many major floods, affecting an area of up to 77% with about 66% city dwellers being submerged. Floods in Dhaka affect the basic elements of a smart city such as water supply, transport, and housing by displacing city dwellers. Impacts and damage of extreme flooding that occurred in 1987 and 1988 (two times) hit Dhaka City, causing an enormous loss of life and livelihoods and damage to property, which brought into focus the urgent need for immediate governance. Subsequently, the Government of Bangladesh (GoB) prepared an urgent flood protection and drainage plan including flood embankments, reinforced

concrete walls, and drainage/flood regulation structures such as sluices and pumping stations and has banned the filling in of any wetland for urban development. In 1989, an FAP was specifically issued protecting Dhaka City from flooding, covering flood management such as flood mitigation and drainage improvement to provide a secure living environment for city dwellers, and the Structure Plan of Dhaka Metropolitan Development Plan (DMDP) 1995–2015 was formulated, focusing on the FAP. However, to protect Dhaka City from flooding, dredging work in the surrounding rivers such as Buriganga, Turag, and Balu has been regularly carried out. Massive construction work was also commenced in 1989 to provide flood protection facilities to the most highly urbanized areas, covering about 87% of Dhaka City. In addition to structural measures, nonstructural measures such as flood forecasting and warning and evacuation have been institutionalized to ensure the status of smart city by reducing flood damage. In this respect National Water Policy 1999 can be understood, which emphasizes water-related problems and risk zoning; it focuses on flood proofing, both structural and nonstructural for flood management, early warning, and preparedness. Other major initiatives are the Flood Hydrology Study, Flood Management Study, National Water Plan, and the Flood Warning System Study.

Wetlands are important features of nature and considered an ecological safety valve, which are described as natural security in maintaining the environment. Dhaka was built on the higher terrain and encompasses a river, network of canals, and wetlands. But with the increasing population, the low-lying areas of Dhaka city are being occupied over a period of years owing to the settlement of migrants, rapid expansion of housing, industrialization, and infrastructural development, which cause damage to the natural drainage system of Dhaka, and frequently occurring water congestion and water logging affecting the surrounding ecology and biodiversity. There are many sectoral laws in nature related to water bodies that exist in the country, such as the Bengal Canal act 1864, East Bengal Embankment and Drainage Act 1952, Ground Water Management Act Ordinance 1985, and Water Supply and Sewerage Authority Act 1996. Focusing the pollution of water bodies the Government has enacted the Bangladesh Environment Protection Act 1996. In 2000, the government enacted the Natural Water Bodies Protection Act for the rational use of wetlands in development and settlement works. This Act particularly prohibits any sort of development activities on the wetlands in the Dhaka Metropolitan Development Plan area; issued a detailed area plan (DAP), which has given precedence to eliminating water logging and drainage congestion in Dhaka city; and the Structure Plan of DMDP 1995–2015 for drainage capacity adjustment, a comprehensive drainage development plan and improvement of the drainage management system. The annual loss of wetlands in and around Dhaka city during 1989–1999 was 1.23%, which increased to 5.70% during 1999–2003. If this rate of loss continues then there will be no wetlands in and around Dhaka city in the near future. Thus, further loss of wetlands need to be prevented to mitigate the adverse impact of disaster for balancing the ecosystem and better living of city dwellers.

Experts indicate the possibility of an impending earthquake striking Bangladesh at any time in the future. Dhaka city is at a high risk for earthquake owing to its unplanned urban growth, inadequate infrastructure, and uncontrolled urbanization

resulting in incredibly high population density. A huge number of buildings have been built in Dhaka city flouting the Bangladesh National Building Code, which did not even exist prior to 1993, and more buildings exceeded the number of floors and space then allowed in the approved plan. The present Mayor of Dhaka South City claimed while speaking in a roundtable discussion in March 2019 that around 5500 buildings have been constructed in the capital illegally. Meanwhile, the Government (Bangladesh Inland Water Transport Authority) demolished about 2000 illegal structures along the Buriganga River in Dhaka city in its eviction drive and Dhaka City Corporations have been demolishing the unauthorized constructed/built/extended portions of the structures. However, the earthquake hazards can never be resisted, but the impact in Dhaka city can be reduced/limited by introducing proper policy and planning for disaster management, community awareness build-up and training, proper implementation of the national building code, and enrichment of a well-equipped rescue team. As precautionary policy measures there are the Bangladesh National Building Code, 1993, and the Dhaka Metropolitan Building Construction Rules, 2006, to cover planning administration and enforcement, and general building controls and regulations for earthquake safety and fire protection. In order to face the post-earthquake situation Bangladesh government has taken initiatives to recruit 70,260 urban volunteers and has procured 7496 pieces of equipment for search and rescue-related operations and has a plan to procure another 2154 pieces of disaster-related equipment with the support of the Japanese government (GoB, 2015).

Almost all cities of the globe are more or less affected by pollution, but Dhaka city has reached the highest level. Air and water pollution are the varieties of man-made/technological disasters to the environment that have taken place in Dhaka city creating obstacles to safe and healthy living and affecting with different kinds of fatal diseases. The environmental degradation situation in Dhaka City has arisen out of a lack proper sewage and sanitation for a huge number of residents, particularly the poor who live in the slums; polluting effluents from vehicles, industries, and the presence of brick fields and tanneries in and around Dhaka. The tannery at Hazaribag in Dhaka city and water vehicles plying trade in the Buriganga, Turag, and Balu rivers, are responsible for severe water pollution. However, recently the Government has endured the sifting of all tanneries from Dhaka city to Savar. The unauthorized and open space piling of generated solid waste in Dhaka profoundly impacts the quality of life city dwellers. Dhaka city dwellers are also exposed to noise and odor pollution. As a part of governance and policy, in 1977 The Environmental Pollution Control Ordinance promulgated ambient air quality standards, vehicular exhaust emission standards, river mechanized transport emission standards, and gaseous emission for industries or project standards; in 1989 The Department of Environment Pollution Control was renamed The Department of the Environment, which reflects the seriousness of the government in dealing with environmental pollution; in 1995 the Environmental Conservation Act was enacted, which also contains laws as regards the protection of environmental health and the control of environmental pollution; in 2018 the shifting of all tanneries from Hazaribagh to outside of Dhaka city was completed with strict initiatives and

monitoring by the government; the government banned wood as a primary fuel in the brake-making process in and around Dhaka city and the Dhaka City Corporations built many shades for temporary dumping of waste. Dhaka city has recently been identified as the city with the worst air pollution city in the world. In this situation, in a ruling on 26 November 2019 the High Court Division of The Supreme Court of Bangladesh banned the operation of all brick fields situated near Dhaka city in the districts of Narayanganj, Mushiganj, Manikganj, and Gazipur. Environmental problems in Dhaka city are also created by the transport sector and pollution generated by fuel-burning defective motor vehicles, which is one of the major health hazards and causes of road congestion in Dhaka city. The Government has enacted Transport Policy 2019 to tackle the situation.

Occurrence of fire incidents is a common phenomenon in Dhaka city, particularly in the dry season. Fire that break out in slums, garment factories, and small manufacturing industries are regular news items during that season. Fire hazards that occur in Dhaka city causing a huge loss of lives and assets almost every year are termed accidents, but most fire events are far from being accidental and are preventable (GoB, 2010); fire hazard is a technological disaster that has led to disrupted living conditions of city dwellers and hampered Dhaka from becoming a smart city. Increased population has been linked to the increasing frequency of fires in Dhaka city. Faulty electric wires, higher power loads, loose connections, use of old equipment, unsafe use of chemicals, old and risky gas pipelines, and petrol and CNG/LPG stations at improper places are responsible for most of the fire incidents in Dhaka city. In 2018 alone, at least 468 fire incidents were reported in Dhaka city and among which the horrific Nimtoli fire of 2010 killed 124 people, the Chawkbazar fire of 2019 killed 71 people, and the Tazreen Fashions Factory fire of 2012 killed 112 people. In all cases, fires were caused and had a devastating effect because of the unregulated chemical warehouses in Nimtoli and Chawkbazar. Factory fires occurred owing to poor planning and weak infrastructure. The Factories Rules 1979, Fire Prevention and Extinguishing Rules 2003, Bangladesh National Building Code 1993 and Dhaka Metropolitan Building Construction Rules 2006 provide broad guidelines on fighting fires, evacuation systems, and directives for making buildings relatively safe from fire hazards. Every year in April the Bangladesh Fire Service and Civil Defense observes fire prevention week for awareness building.

Dhaka is well known as a city of rickshaws, manually driven nonmechanized vehicle popular with lower- and middle-class city dwellers. Rickshaws are pollution free but are a cause of road congestion in the city. Dhaka city offers 65% of jobs in the informal sector, among which largest portion is in the rickshaw sector (Mukherjee, 2006). However, in addition to rickshaws, private cars, buses, minibuses, taxis, tempos (baby taxis), and three-wheelers (auto-rickshaws) are the essence of transport in Dhaka city; emissions from these mechanized vehicles are one of the major sources of environmental pollution in Dhaka city. Improperly maintained vehicles and the use of leaded gasoline vehicles are responsible for polluting Dhaka. A study revealed that in Dhaka city, 80% of buses, 90% of trucks and 80% of tempos have been polluting the city by discharging high levels of carbon monoxide emission. To ease the situation from the governance angle in 2006, the

Strategic Transport Plan was adopted for the creation of environmental pollution control standards with a special emphasis on emission from vehicles. In 2002, legislation was introduced for the use of relatively environmentally friendly CNG in vehicles and following the legislation, two-stroke auto-rickshaws, the largest contributors to the city's air pollution, were banned in Dhaka city. The Bangladesh Road Transport Authority, Road Transport Committee, Dhaka City Corporation, and have been playing regulatory functions and the Dhaka Metropolitan Police (DMP) is the implementing authority of traffic management in Dhaka City's transport system.

Dhaka City dwellers face the most serious problems such as traffic jams in their daily life, which consists of 3.2 million work hours per day. Increasing numbers of vehicles on the city's roads contributes to more air pollution emissions and hampers the living standards of city residents. In this situation, the Government has already revised the Strategic Transport Plan for 20 years (2015–2035) to enhance traffic speed. The government has massive plans for Dhaka city. To increase traffic speed and improve living standards of Dhaka city dwellers the Government has taken up plans/projects to build Metro-rail, an Elevated Express Way, and a Digital Traffic System. The projects are being implemented and yet to be completed soon. Metro-rail will certainly help to reduce the number of vehicles in Dhaka city; the Elevated Express Way and the Digital Traffic System will increase the average traffic speed and thus help to reduce emissions from vehicles in Dhaka city and to improve the living standards of city dwellers.

With the economic progress of the country poverty has been declining with improvement of the material wellbeing of the citizens. Dhaka city provides large share of goods, employment, housing, and amenities to enjoy comfortable living and thus, needs a stable electricity supply, water supply, and soil waste management system with assurance of improved service delivery in this regard. Bangladesh now has 23,548 MW installed capacity of electricity and 97% of households have access to electricity (GoB, 2020). Ensuring the distribution of electricity irrespective of slum and nonslum areas through a definite entity is very concerning for Dhaka being smart city. Power generation and transmission distribution to the end users lies entirely with Bangladesh Power Development. In 1977 the Government formed the Rural Electrification Board to ensure the rural distribution of electricity. In 1990 the Dhaka Electric Supply Authority (DESA) was established to provide improved service delivery within Dhaka city. In 2008, the Dhaka Power Distribution Company Limited (DPDC) was formed and took over DESA. The DPDC covers the southern part and the Dhaka Electric Supply Coorporation (DESCO) covers the northern part of Dhaka city. This two authorities are responsible for ensuring the distribution quality of electricity to the city consumers of their jurisdiction and related commercial functions. A few years back frequent power cuts for about 4–5 h a day were common in Dhaka city owing to constraints in the distribution of electricity (IGS-BRACK, 2012). This situation has changed with the expansion of the generating capacity of the country. Now, the city dwellers are getting uninterrupted electricity. However, there are still illegal connections, particularly in the slum dweller area of Dhaka city and corrupt practices in the case of providing service to faulty connection line repair. To ensure water supply delivery, the Dhaka Water

Supply and Sewerage Authority (DWASA) Dhaka Water Supply and Sewerage Authority (DWASA), established in 1963, further endorsed by the WASA Act, 1996, is responsible for providing water, sewerage, and drainage services to Dhaka city citizens. At present DWASA has 311,064 registered consumers, mostly in the nonslum area of Dhaka city. With its 2842-km distribution line DWASA has been meeting the consumers' daily demand of 3152 million liters of water; DWASA produce 3204 liters daily (Water Supply Master Plan, 2021). Almost 100% of Dhaka city dwellers of nonslum areas and only 34% of slum residents are covered by the DWASA water supply distribution line network (IGS BRAC, 2012). The rest of Dhaka city dwellers have to manage water by their own arrangement from various sources such as their own wells, water vendors, private companies, and non-governmental organizations. Dhaka is a rapidly growing city with a growing population and hence its water requirements need to be met through formal channels for the well-being of the dwellers.

The responsibility for solid waste management (SWM) lies with the City Corporations (Dhaka North and South City Corporations). There is definitely no law for SWM except that corporations have the Conservancy Department to collect waste from the source for dumping in a specific place. Open-place dumping of waste is one of the causes pollution-related problems in Dhaka city, with health hazards. Dhaka city generates about 4750 Mt of waste daily (Menon, 2002). Among the produced waste 78% are residential, 20% industrial, 1% institutional, and remaining 1% others; from the source city corporations are supposed collect all waste, but they provide only 85% of services; the rest is found here and there in the streets and drains (Rahman & Rahman, 2011). The slum/poor of Dhaka city can hardly be served by the City Corporations because of the inaccessibility of their garbage vehicles and thus, community members are encouraged to develop participatory type waste management/disposal (Islam & Shafi, 2004). In most smart cities waste is separated for recycle and reuse. Here in Dhaka city there is a small arrangement for the separation of waste for recycling, but there is a dismantling facility in the formal sector that is yet to be developed. In the informal sector separation of waste for recycling is done and many children and women are involved in the recycling process, but there are health hazards (Ahsan et al., 1991). About 120,000 urban poor are involved in the recycling trade chain of Dhaka city (ESDO, 2010). This recycling process is very injurious and hazardous and there is no specific management guideline or regulation. The waste activities in Dhaka including production, import/export, and recycling, etc., are carried out under the provision of (i) the Bangladesh Environment Conservation Act 2010, (ii) the Chemical Substance Depleting Ozone Layer (Control) Policy 2004, (iii) the Sound Pollution Policy 2006, (v) the Bangladesh Environment Conservation Policy 2010, (iv) the Hazardous Waste and Ship Breaking Waste Management Policy 2011, (vii) the Bangladesh Bio-safety Rules 2012, (viii) the Import Policy Order, (ix) the National Environment policy 1992, and the (x) The Environmental Conservation Rules 1997 and The Environmental Court Act 2000. So, to make Dhaka a clean and pollution-free smart city SWM has to be improved on a priority basis. However, under the arrangement of Dhaka North City Corporation an electricity generation plant, with

the technical assistance of a Chinese company, is going to be installed using city waste as a raw material. The plant is expected to come into operation within the next 2 years, and then the SWM scenario of Dhaka city will change.

Poverty and inequality are very common in the slums of Dhaka city, thanks to the main cause: crime (Hossain, 2011). A study revealed that 17% of the total crime of the country occurs in Dhaka city (Shafi, 2010). Crimes such as the abuse of narcotics and its illegal trade, repression of women and children, kidnapping, murder, theft, robbery, and possession of illegal arms and ammunition have been recorded as often witnessed in Dhaka city. In January to June 2005, a total of 2000 crimes, including 120 murders, were committed in Dhaka city (Shafi, 2005). In January to July 2015, a total of 544 persons were arrested in 251 cases for their involvement in illegal arms and ammunition from Dhaka city (Khan, 2015). In addition to these sorts of criminality, political violence, and intra-party clashes, religious fundamentalism, and even terrorist attacks have risen in Dhaka city, which hampers the lives of city dwellers. There are hardly any newspapers without the news of drug addiction, hijacking, illegal arms cases, torture/trafficking of women and children, and the presence of activities of thugs. All the regions are not equally crime prone; crime varies with socio-economic factors (Cohn, 1990). Poverty and inequality are the main reasons for the existence of crime in Dhaka city, particularly in the slum area. Therefore, the Government established the Dhaka Metropolitan Police in 1976 to maintain complex law enforcement procedures in the city area. With the speed of crime and violence the Government was forced to form an anticrime force such as the Rapid Action Battalion with trained forces from the Bangladesh Army, Navy Airforce, and Bangladesh Police (Nazrul Islam, 2005). However, the country has made many improvements in controlling religiously fundamentalist terrorist violence and Dhaka is now more free of violence for city dwellers.

Actions for Improvement and Conclusion

To make Dhaka a more livable and smarter city by 2035 the policy makers of the country have prepared and finalized the Detailed Area Plan- 2016–2035 (DAP). The DAP is a huge document with a massive amount of data regarding the future of Dhaka city. RAJUK initiated the DAP work back in 2016 and it covers almost every aspect of the city, from land use to a demarcation of canals and flood flow areas. Under the DAP, Dhaka city will be renamed Dhaka Metropolitan Region (DMR), which includes Gazipur and Narayanganj City Corporation, Banshi River in Savar, Kaliganj-Rupganj, and Keraniganj, covering an area of 1528 km². The DAP will help to make DMR an eco-friendly, livable, and smarter city with a rapid and efficient interconnecting transport system. With the implementation of DAP policy makers want to keep the population density of different areas of Dhaka proportionate to civic amenities and to develop planned infrastructures for accommodating more than 60 lakh (6 million) people. Presently, there are some certain areas of old Dhaka with a population density of 700–800 per acre. The DAP wants to maintain a population density per acre of 250 in old Dhaka; 200 in central Dhaka; 180 in the

Gazipur, Narayanganj, Savar, Kaliganj-Rupganj, and Keraniganj areas; and 150 in other urban areas. There exist 228 km of inter-regional connecting roads in Dhaka, which is planned to increase to 291 km. The DAP has also a plan to extend the collector road by 1200 km, create a 202-km cycle lane, and 574 km of waterways in its area. The DAP has identified 54 locations to build 650- to 700-ft² (60 to 65 m²) housing flats by RAJUK and Real Estate Companies for lower- and lower middle-class people, providing them with special incentives. To build Dhaka eco-friendly and smarter the DAP has planned to create and construct 5 large regional parks, 49 water parks, 8 large eco-parks, another 9 parks and playgrounds; and 627 schools and 287 hospitals to ensure the education and health of the city dwellers; and to create a cultural zone surrounding the Buriganga river preserving the historical sites and turning them into tourism and recreation centers.

With the increasing rapid development of Dhaka city the disasters and their impacts are increasing. Disasters cause loss of life, properties, and years of development. Like other smart cities, Dhaka city is an integration of transportation, water supply, sanitation, housing, other infrastructure, and service system; strengthening these systems may increase the resilience and help in disaster governance in Dhaka city. Smart cities use ICT. Bangladesh has launched its first satellite “Bangabandhu-1” on 12 May 2018, from which Dhaka city will also benefit with uninterrupted internet service, a faster broadcast service, and effective disaster preparedness, which will ultimately improve city services and disaster resilience. However, good governance, effectiveness and efficiency in policy planning are the ultimate ways in which to make Dhaka city disaster resilient and have a major impact on communities’ preparedness and capacities to recover. There are plans and programs for disaster governance make Dhaka a smart city, but it is also a fact that the city has largely grown in an unplanned manner, thus making it vulnerable during disaster. The Bangladesh Water Development Board, Bangladesh Fire Service and Civil Defense, RAJUK, Bangladesh Road Transport Authority, and Dhaka City Corporations are the vital agencies on disaster mitigation initiatives, which led to the development of policies and proper monitoring to control and enforce policy/rules for Dhaka city to be smart. The Government enacted/adopted/issued the Disaster Management Act, National Disaster Management Policy, National Plan for Disaster Management, and the Standing Order on Disasters for the governance of risk reduction and emergency response management, and formed a separate Ministry of Disaster Management and Relief as a key point on disaster governance. Policy implementation is a great challenge in such a huge population of Dhaka city that needs to be given due importance with preferences and options of different stakeholders. Now it needs the integrated efforts of government organizations, nongovernmental organizations, civil society, researchers, scientists, and media; an effective response across the city dwellers; implementation of major policies/plans/programs to ensure a proper monitoring and accountability system and that may help to achieve good disaster governance in building Dhaka as a smart city.

Smart cities require monitoring of pollution levels, water runoff, and even sewage system overflows, and getting these functions back following a disaster, keeping a city habitable; preventing loss of properties from disasters through preemptive repair

works of identified bad/weak infrastructure; developing systems in such a manner that response times to disasters can be reduced and assessing loss and needs of the victims in the event of a disaster; developing ICT and ensuring safe access to social media so that family and friends outside the disaster-affected area can know/get the real picture of the victims, even when traditional communication is a challenge; reducing the impact of a disaster, creating sustainable designs that consider the natural landscape and any changing climate concerns. These common actions, in terms of policy governance, are equally applicable for Dhaka city too. However, some specific actions are recommended to ensure and improve the smart nature of Dhaka city addressing the disaster risk reduction (DRR) and adaptation to climate change through initiatives with policy formulation and proper governance:

- a. The authorities concerned should take reasonable measures to protect related wetlands, water bodies, and rivers in and around Dhaka city for its survival.
- b. The Government has already issued a decree banning the filling in of any wetland for urban development. Thus, proper land development rules should be introduced without delay to minimize the loss from river flooding from the surrounding rivers of Dhaka city.
- c. Sewage facilities for every corner of Dhaka city, particularly in the slum area, to be ensured to improve the living standard of residents and remove the potential risk to their health, hygiene, and sanitation.
- d. Emissions from vehicles and industries in and around Dhaka city should be strictly regulated at the cost of the owner through proper legislation and its enforcement.
- e. Open and unauthorized dumping of solid wastes in Dhaka city are a source of disease-carrying insects and germs, which need to be properly managed and thus the existing infrastructure should be adequate to handle the huge amount of waste produced every day.
- f. The Department of Environment should monitor the air quality of Dhaka city and data on suspended particulates in the air and the regular publication of such data through news and social media to generate mass awareness of the threat of pollution.
- g. The authorities concerned should ensure regular and careful maintenance of the infrastructure of Dhaka city through proper monitoring.
- h. Natural disasters in Dhaka city would be unavoidable consequences of the impact of climate change and thus a comprehensive disaster management plan is required to be kept in mind for DRR.
- i. Manufacturing industries inside the DMP area attracts poor migrants from other parts of the country to be reallocated to improve traffic congestion and pollution levels and the standard of living of Dhaka city dwellers.
- j. It is observed that most of the fire occurrences in Dhaka city are caused by electrical problems; thus, electrical lines and connections in the infrastructure should be installed with proper sustainable design and regular maintenance has to be ensured in the case of any deviation. On the other hand, any unauthorized connection has to be removed immediately, ensuring proper monitoring.

- k. There are many fire stations in Dhaka city to handle fire occurrences; their capacity needs to improve in such an integrated framework, combined with information and communication systems to alleviate the damage and suffering of the people due to fire.
- l. The application of good and effective scientific management can help the authorities to find better outcomes in the case of criminality and violence in Dhaka city where millions of people live. The law-enforcing agencies of Dhaka city should have to maintain large databases so that they can use those data successfully to understand the problem, take necessary actions, deploying forces, and managing any situation successfully.
- m. The authority should apply existing policy regulations on disaster prevention and mitigation, building infrastructure without any exceptions, and take legal actions against the violators irrespective of their political and social identity.
- n. Appropriate customized software should be developed and to assess the level of fire hazard risk for buildings and industries, as well as measure the quality of fire protection facilities.
- o. A framework should be initiated to facilitate the development of an integrated information system for hazard management and effective handling of disasters in Dhaka city.
- p. Concerned authorities should be pro-active in preventing a building from being erected that violates the construction permit and the violator should brought under law.
- q. Communications technology helps city residents in emergency disaster response and disseminates information to warn people about the current conditions during and after disasters; thus, a holistic approach needs to be taken to extend ICT to all city dwellers at an affordable cost.

Water supply, an assured electricity supply, sanitation, including solid waste management, efficient urban mobility and public transport, affordable housing, smart law-enforcing agencies preventing crimes, programs for poverty elevation, ICT connectivity and digitalization, good governance, especially e-Governance, etc., all exist in Dhaka city; the question is whether they are adequate and can deliver efficiency. Dhaka, with its huge and increased population, has the potential be a smart city. To support its goal to become a smart city, the policy makers at a national level must address the planning needs for achieving sustainable development facing and mitigating disasters in and around Dhaka city. Being a capital city, Dhaka should ensure planned development in both living and livelihoods to be attractive to its residents and settlers. Professionals related to city planning and specialized institutions responsible for governance and policy implementation have a lot to do in respect of raising its standard as a smart city. Government strategies should be connecting city dwellers through information networks to address the challenge of regulations, relevance, and awareness. Thus, the incorporation of ICT into planning practices should occur, with purposeful actions of decision makers and those who regulate and support planning for building Dhaka as a smart city, helping to enhance community resilience to disasters.

Abstract

Owing to its unique geoclimatic condition, India is highly susceptible to sundry natural catastrophes, such as earthquakes, landslides, and other hydro-meteorological disasters. The Indian shoreline is 7516 km, making the 13 coastal states and union territories subjected to 10% of the world's tropical cyclones. Since time immemorial, libraries have been imperiled by various disrupting calamities that severely alter their usual functionality. Libraries have endured numerous disasters, including cyclones, fires, floods, earthquakes, and hurricanes, in addition to the harm caused by war and terrorism. So, libraries need to consider disaster risk reduction for resilience building. This chapter explores the disaster preparedness of libraries in the coastline areas of India and demonstrates the disaster preparedness of libraries in gauging their current resilience levels to natural hazards, specifically cyclones. Thus, this study exhibits an outline of Indian libraries' disaster preparedness in coastal areas. The chapter discusses the research work's findings and extrapolates the significance of disaster management plans in libraries. The study's conclusion urges the enactment of the disaster management plan and the obligation of training for disaster preparedness

Introduction

Since time immemorial, libraries worldwide have encountered disasters in various forms caused by natural and manmade incidents. From fire to floods, earthquakes and hurricanes, libraries have gone through and through various disasters, together with the damage initiated by war and terrorism (Hussein Moustafa, 2015; Kaur, 2009; Najar & Wani, 2021; Superio et al., 2019; Thiem, 1979; Wani & Ganaie, 2017). Libraries, academic or public in nature, hold a collection of cultural significance along with the general collection, and we are liable to safeguard them against any disaster. However, many are unaware that protecting these unique collections has become an integral part of the international framework for disaster risk reduction (DRR) (Garnett, 2021). The history of library disasters communicates the abject account of the obliteration of libraries and the forfeiture of treasured collections of cultural importance. From the burning of the Great Library of Alexandria to the libraries destroyed in the war, many valuable collections have been lost due to natural or anthropogenic disasters (Heller-roazen, 2018; Moustafa, 2013). Libraries around the globe have also faced large-scale disasters initiated by cyclones. In 2004, the Asian tsunami damaged several libraries in Sri Lanka and Indonesia. Correspondingly, various libraries in the United States were destroyed by two hurricanes, namely, Katrina and Rita, in 2005. Additionally, much literature has also reported the catastrophe done by Typhoon Haiyan in the Philippines in 2013 (Amarasiri, 2005; Corrigan, 2008; Diamond, 2006; Mabe, 2015; Nevins & Nyberg, 2007; Shaw, 2015; Superio et al., 2017; Topper, 2011). In May 2019, Odisha was hit by the highly severe “Cyclone Fani,” which caused damage to library books, administrative buildings, and boundary walls in 18 Teacher Education Institutions (TEI), including Elementary Teacher Education Institutions (ETEI), District Institute of Education and Training (DIET), and Colleges of Teacher Education (CTE) across eight districts. Damage to cultural institutions, including museums and libraries (HKM State Library, District Library, Odisha State Museum, Odisha State Archaeology, Anand Bhawan, Madhu Smriti, BK College of Art & Craft, Swaraj Ashram, Sanskruti Bhawan, Utkal Sangeet Maha Vidyalaya, Odisha State Archives, GKCM Odissi Research Center, OIMSEAS, Utkal University of Culture, Netaji Museum, Netaji Memorial Museum), was reported in Cuttack, Khurda, and Puri as well (“Cyclone Fani: Damage, loss, and needs assessment,” 2019).

Correspondingly, the libraries, museums, and art galleries of the magnificent medieval city of Florence were irreparably damaged by the flood in Florence in

1966 (Clarke, 2002). During the great flood of 1997, many Polish libraries lost volumes of their collection. Piotrowicz (2010) reported that 40,000 volumes of periodicals from 1929 to 1945 were damaged by the water. Correspondingly, Colorado State University's Morgan Library experienced water damage in 1997, resulting in the loss of 500,000 books from its basement. It took 7 years, numerous millions of dollars, and countless staff hours to process approximately 100,000 gift volumes, repair 163,377 damaged volumes, and repurchase more than 63,000 highly used total loss volumes in the library's response and recovery operations. There were at least 192,000 volumes that were either categorized as "complete loss" or were not recovered but were nonetheless permanently lost to the collection (Lunde & Smith, 2009). A flood in Punjab, India, destroyed 44,535 articles. India experienced tremendous floods on the evening of July 11, 1993, which impacted the Thapar University Library and the Panjabi University Library. For 4–5 days, the Thapar Technology Campus was covered by 1.4–2.4 meters of water. Out of the 63,000 objects in the university library, 44,535 were destroyed. The library also lost computers, photocopiers, and CDs. Except for the damage to a voltage stabilizer, there were very few losses to the collection and equipment at Panjabi University Library. Only those books that users who resided in flood-affected areas had borrowed were damaged. Similar to this, about half of the library resources were lost, and numerous libraries' physical infrastructure was seriously damaged by the 2014 flood in Kashmir. For at least 2 months, library services were suspended (Kaur, 2009; Wani & Ganaie, 2017). In Iran, 39 public libraries were shuttered, 3 were evacuated, and 1 was destroyed during the recent flood, according to the official reports of the Iran Public Libraries Organization. According to the Public Libraries Institution's report on the incidents involving the public libraries under its supervision, 171 libraries have suffered damage. A total of 171 libraries have been damaged overall in 16 provinces, most of which have been dampened, and 1 library has been completely submerged in water. In addition, two libraries that were 80% complete were devastated. Due to the landslides and their proximity to the dam and the river, three libraries were also evacuated (Pazooki & Saboori, 2021). Besides the damage caused by natural disasters like floods, cyclones, or hurricanes, libraries have also lost their prized holding in anthropogenic disasters. Throughout history, numerous libraries have been destroyed by fire. A famous illustration of how a fire can destroy a collection is the burning of the magnificent Library of Alexandria. Even if there is disagreement over who set the fire, the fact remains that a sizable portion of the collection was destroyed. Like this, Khilji destroyed nine million manuscripts in the library of Nalanda University. Moreover, two-thirds of the 55,000 books in the Library of Congress were destroyed in the largest fire in the library's history on December 24, 1851. In another fire incident, the Norfolk and Norwich Central Library was also destroyed (Gupta, 2018; Hammond, 1996; Musharraf, 2016; Thorburn, 1994).

Cultural wars have also been the reason for the destruction of many great libraries. The best public library in China was thought to be the Oriental Library in Shanghai. According to the statistics from the 1932 Symposium, the library had a substantial number of rare book collections, more than 600,000 volumes in different

languages, and subscriptions to more than 700 magazines. Both a number of priceless first editions from the Sung Dynasty and one of China's most significant collections, the Yen Feng Lau classics collection, were destroyed in the Sino-Japanese War that began in 1937 (Zgonjanin, 2005). During the US incursion on Iraq, many universities and libraries were burned and looted, along with the media equipment. Many Iraqi libraries had a personnel and leadership crisis that exacerbated their material losses, and librarians fled the country (Moustafa, 2013). Consequently, all libraries must include disaster management as a vital part of library management because a thorough disaster management plan can eradicate the chaos by ensuring that logical and appropriate decisions are being made during the disaster (Morgan & Smith, 1997).

Library disaster management encompasses disaster control planning, risk assessment, and staff training. The first step in disaster management is to design a catastrophe preparedness strategy. It is the most significant policy and training document, and it necessitates ongoing managerial commitment and organizational support in the form of a catastrophe awareness and preventive culture. The primary objective of a disaster preparedness plan is to bring down the risks and enhance the efficiency of response during the disaster. For crafting an operational plan, the institution must have thoroughly analyzed the reasons for the disaster, be aware of accessible resources and practices for dealing with a disaster, and sustain a constant commitment to advocating and executing the plan's recommendations (Matthews & Eden, 1996; McIlwaine, 2006; Muir & Shenton, 2002). Despite being an essential part of any library management, many studies have found that libraries fail to implement disaster management plans in general (Ayoung et al., 2016; Kaur, 2009; Kostagiolas et al., 2011). Though the literature on the aftermath of cyclones is few, the investigators found few excellent studies that recognized the response and recovery of libraries that have experienced the wrath of cyclones. Amarasiri (2005) documented the damage caused by the tsunami in Sri Lankan libraries and emphasized the psychological trauma of librarians in affected libraries while accounting for the rebuilding efforts of libraries from scratch. He also expressed the dire need for libraries' effective disaster preparedness plans.

Corrigan (2008) described the experience of numerous academic libraries in New Orleans ruthlessly impacted by Hurricane Katrina. He accounted for the remarkable efforts of Tulane University to protect collections and stabilize flooded library buildings. Skinner (2007) gave a succinct analysis of the magnitude of loss at the academic libraries before recounting the devastation and recuperation of the library at Xavier University. He also provided a list of problems that librarians in flood-prone locations may ask over to plan for the potential of a large flood and its implication. However, Superio et al. (2017) documented the effect of Typhoon Haiyan on academic libraries in Northern Panay, the Philippines, and the disaster management methods that were put into effect. The outcomes disclosed that even though most libraries do not have a disaster management plan, but they all had standard disaster management practices that facilitated them to protect parts of their collections. Furthermore, the study showed that librarians were deficient in knowledge and skills in disaster management. In addition, Hurricane Katrina and

Hurricane Rita have been the most devastating disasters faced by the libraries, especially in New Orleans, Mississippi, Louisiana, and Illinois, the United States. The experience of these libraries in response and recovery to the damage done by the hurricane can be a lesson for other libraries as the studies found that despite having a disaster management plan libraries failed to safeguard themselves from the destruction as the measures were inadequate to tackle such large-scale disasters (Diamond, 2006; Ellis, 2007; Hamilton, 2011; Shaw, 2015; Topper, 2011). In the same way, Frank (2011) also concluded that Gulf Coast libraries in the United States have ineffectual disaster and preparedness plans to render the massive destruction caused by hurricanes. However, disaster management remains a neglected area in India after tsunami awareness has been raised regarding the importance of disaster planning (Kaur, 2016). Subsequently, it is evident from the literature that libraries being the vital institution of the community lack the management of disaster. Though libraries in foreign countries are aware of the importance of disaster plans in India, library professionals are still inconsiderate. As India stands vulnerable to various natural disasters, it is crucial to realize the importance of a well-documented disaster plan in general. Thus, this is the first study that strives to determine the status of disaster management plans in general while converging on libraries' prevalent disaster management practices, particularly for tropical cyclones.

This study centers on the disaster management practices of academic libraries located in the coastline areas of India. The investigators opted to implement the survey method by administering the questionnaire as a research tool to fulfill the study's purpose. A similar study was conducted by Superio et al. (2017) on the academic libraries of the Philippines. Therefore, the investigators adopted the scale developed by the mentioned author to root out the data. The questionnaire consists of 30 close-ended questions and 2 open-ended questions in the following subsections:

- A. Demographic information
- B. About the library
- C. Disaster management practices
- D. Preparation before the cyclone struck
- E. Impact of the cyclone on the library
- F. Post-cyclone responses and recovery efforts
- G. Realization and lessons learned

After identifying nine states (*Andhra Pradesh, Goa, Gujarat, Maharashtra, Kerala, Tamil Nadu, Karnataka, Odisha, and West Bengal*) susceptible to cyclones, the investigators retrieved the email IDs and contact numbers of approximately 80 librarians working in the academic libraries (central as well as state university) located in these states. As the country's academic institutions were closed for walk-ins, due to pandemic the investigators were bound to collect data via online mode. Employing Google Forms, an online questionnaire link was created and sent out to the librarians via email. Regrettably, a few email IDs were found invalid, and the investigators tried to reach them via WhatsApp. Notably, few respondents expressed their inability to provide data as the libraries have done nothing for the management

Table 1 List of the respondents

Name of the institution	Location
Central University of Tamil Nadu, Thiruvarur	Tamil Nadu
Yashwantrao Chavan Maharashtra Open University, Nashik	Maharashtra
Goa University, Taleigao Plateau	Goa
Indian Institute of Teacher Education, Gandhinagar	Gujarat
The Maharaja Sayajirao University of Baroda, Vadodara	Gujarat
The WB National University of Juridical Sciences, Kolkata	West Bengal
National Law University, Cuttack	Odisha
University of Calicut, Malappuram	Kerala
Cochin University of Science and Technology, Kochi	Kerala
Karnataka Veterinary, Animal and Fisheries Sciences University, Bidar	Karnataka

of disaster; this scenario exhibits the obligation of instituting recognition of disaster management in academic libraries. The link to the online questionnaire was accessible from early January 2022 to mid-March 2022. Despite the several reminders and follow-ups, the investigators succeeded in getting only 12.5% (10 out of 80) responses from the target population. Then the accumulated data was imported to MS Excel Office 365 for analysis and interpretation. Table 1 displays the list of universities that take part in the survey.

Library and Its Structure

The physical structure of any building plays an essential role in protecting it from any disaster. When asked about the physical structure, 80% responded that the libraries were made of concrete while the rest were made with concrete and light materials like wood. Further, 90% of libraries responded that they are in only one building, while 10% had two or more buildings. Likewise, it is also essential to know that the library building is situated far from the shoreline. It was found that 50% of libraries are located within the range of 10 or fewer kilometers from the shoreline, whereas 20% lie within 21–30 km. For now, 10% of libraries are too far from the shoreline. The library's proximity to the shoreline helps determine the chances of risk posed to the library. Libraries in close vicinity of the shoreline are highly likely to be affected by the cyclones.

Disaster Management Plan

A disaster plan is the most important aspect of disaster management because it removes fear and allows for logical and proper decision-making to minimize potential damage (Morgan & Smith, 1997). Though a disaster plan is vital for every library, only one library (The Central Library of Goa University) has been found in

Table 2 Reasons for lacking a disaster management plan ($N = 10$)

Reasons	Frequency	Percentage
No significant holdings of rare books/materials	2	20
Lack of financial resources	1	10
Lack of human resources to implement	0	0
Lack of model to serve as a guide	3	30
No staff available to write a plan	0	0
There is no perceived risk	6	60
No instruction from the parent institution	1	10

Multiple answers were permitted

possession of a disaster management plan. In contrast, the remaining libraries do not have any disaster management plan to refer to for the duration of any emergency. Kaur (2009) has also found that disaster management remains a derelict standpoint in Indian libraries. However, 50% of libraries showed interest in writing disaster management plans, while the other 30% (3) responded that they are in the process of writing one for their library. The usual reason for the lack of disaster management in libraries was that 60% of libraries think there is no perceived risk of disaster like cyclones, followed by a lack of a model to serve as a guide. Also, 20% of libraries responded that they do not have any significant holding of rare books. One library responded that it has no instruction from the parent institution. Cuthbert and Doig (1994) have also accounted that most libraries assume that they do not need any disaster plan because they anticipate no chance of any statistical disaster. Though the unpredictable nature of disaster cannot be taken lightly, as disaster has the potential to strike at any time and any place. Furthermore, a disaster management plan does not deal with the response and recovery of the collection alone, but it also guides the management team on the safety of clients and staff when any disaster strikes. Thus, libraries must seriously consider writing a disaster management plan precisely drafted according to the nature of the library Table 2.

As mentioned above, the disaster management plan deals with the collection of the library and encompasses the security of the building and staff as well as clientele of the library. The library has a disaster management plan that covers the safety procedures of persons and the collection of the library and building. Correspondingly, one library out of two libraries that are in the writing process of a disaster management plan also responded that its disaster plan covers the disaster management practices of upkeeping its building and collection along with the staff and clientele. In contrast, the disaster management plan of the second library involves its building only. The justification for ensuring only the library's building is that the library recognizes no risk of disaster and has considered the safety of library buildings against disasters such as fire.

Disaster management practices such as an updated list of staff that can be contacted in a disaster situation, labeling of collection that mare in salvaging priorities list, technical endorsements/strategies/policies for rescuing damaged

materials, regular building maintenance, conducting drills and exercises in case of disaster, and updated telephone tree help the libraries in minimizing the risk of disaster and guide them in quickly reacting against the disaster (Superio et al., 2017). However, the study found a lack of any such practices among the libraries. However, 90% of libraries have emergency kits such as flashlights and fire extinguishers, which indicates that libraries are mainly concerned about the fire disaster, which is further proven by the availability of fire alarms in 80% of the libraries. Illo et al. (2018) also found that among most libraries disaster management practices are standard for fire disasters only, and libraries have trained their staff to oversee this disaster. In line with the previous statement, the study reveals that most libraries have provided training to their staff in managing the fire extinguishers and have detailed what to do in case of any disaster caused by fire. However, 20% of libraries responded that none of their staff had undergone such training. Besides, having insurance policy is also an essential part of securing library against any disaster. In response to the query about having insurance policy, five (50%) libraries have their building insured, whereas three (30%) have insurance for their collection.

Thus, considering the importance of a disaster management plan, each member of the library must get the necessary training, and libraries must consider enactment of a disaster control plan that summarizes the risks, responsibilities of staff, and strategies related to response and recovery to the disaster (Matthews & Eden, 1996).

Preparation Before the Cyclone Struck

The states the investigators have chosen for conducting research have faced cyclones recently. The Indian Meteorological Department (IMD) issued a warning before the cyclone struck to take adequate measures to reduce the damage done by the disaster. Libraries are no exceptions, and the authority must ensure that the library building is safe enough to face the disaster. As the library's under study has no well-documented plan, still some measures had to be taken to ensure the safety of the library. In response to the preparation of libraries before the cyclone struck, it was found that nine (90%) libraries checked the roof for any possible leaks, while six (60%) repaired the library building and three (30%) put up some items on chair or tables to safeguard them in case of a flood.

Further, two (20%) libraries have covered the collection and library equipment with plastic and waterproof materials. Only one library has relocated its collection to other buildings. These measures have aided the libraries in upholding the collection (Fig. 1).

Impact of the Cyclone on the Library

Figure 2 reveals that 70% of the libraries were untouched by the cyclone, whereas 20% of the libraries reported slight damage like detachment of roof or windows due to the strong wind and water inside the library; however, the collection remained safe

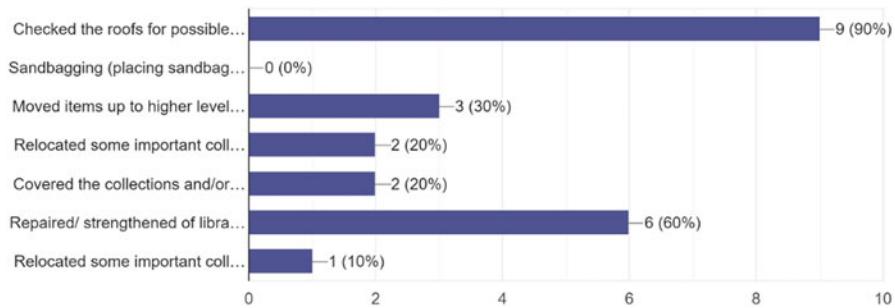

Fig. 1 Preparation before the cyclone

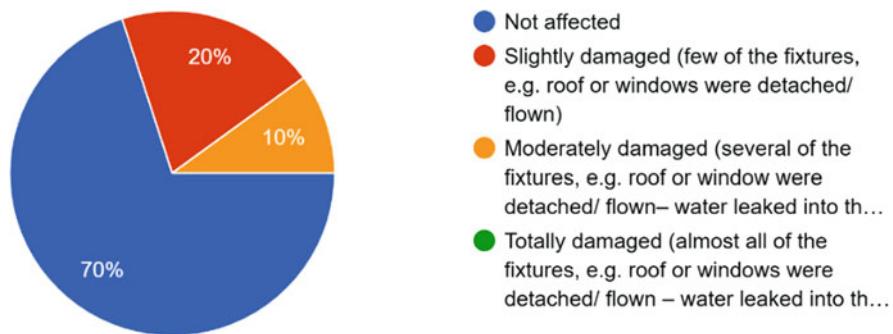

Fig. 2 Impact of cyclone on libraries

from water leakage. Only one library testified moderate damage due to storm surge, several fixtures like detachment of roof and windows and water leakage from the roof were also stated. Additionally, the library that received moderate damage is situated less than 10 km from the shoreline; thus, it can be comprehended that libraries within the range of 20–30 km need to consider implementing disaster management plans more seriously Fig. 2.

Post-Cyclone Responses and Recovery Efforts

It is imperative to check the library after the disaster pass to know the damage caused by the disaster. It was found that 60% of the libraries checked the library a day after the disaster; however, 80% of libraries reported that communication was made among the library staff. As most of the libraries reported being impervious to the cyclone, the libraries that received slight and moderate damage opened the door and windows and drained the water inside the library. Additionally, the libraries also sanitized the building to prevent mold growth. Further, the libraries also removed the wet carpet and affected furniture.

Realization and Lessons Learned

Whatever the extent of damage caused by the disaster, it is essential to take the opportunity to learn from it and utilize it to improve the current practices of tackling any disaster. As mentioned previously, libraries have believed that they are out of danger from any disaster and the good luck of not receiving significant damage from the disaster, and they have paid no heed to dwell on the thought that what if the cyclone has damaged the library to a great extent. Hence, they seem to be not bothered that the disaster could have proven chaotic for them.

Conclusion

This study uncovered that despite being in the high vulnerability zone of the cyclone, most of the libraries have assumed that there is no perceived risk of disaster, especially cyclones in their library. Libraries were unwary to face such type of risk in the future. The library professionals are undertrained for any disaster other than fire. The leading cause behind the unavailability of a disaster management plan was the assumption of library professionals that the library stands out from any disaster. Notably, the lack of cooperation to participate in the survey indicates the wretched status of awareness concerning disaster management in libraries, which further points out that disaster management continues to be an overlooked area in the academic libraries in the country (Kaur, 2009). Whether natural or anthropogenic, disasters are capricious and can bring about destruction to a great extent. Statistically, a disaster may be unlikely to happen in a few places, but that does not mean it cannot happen in the future (Cuthbert & Doig, 1994). A well-written plan that deals with the emergency must be a part of any library management strategy (Owens & Brown-Syed, 1998). Libraries retain valuable collections labeled as a special collection in their inventory that is important to global heritage, and a few libraries under study also have an important special collection of cultural importance. As global warming has skyrocketed the occurrence of natural disasters, libraries cannot ignore the importance of a well-written disaster management plan in the present time. It has become the *need of the hour* to safeguard the precious collection of libraries and staff, and clientele against any disaster. The government of India has undertaken many initiatives for DRR in the nation. Though no specific initiative has been found for the libraries, many government policies and guidelines can serve as a roadmap for libraries in creating their disaster management plan. The National Disaster Management Authority (NDMA) has created a Disaster Management Plan template that the libraries can adapt according to their prerequisite. Other than that, libraries can help in research studies and try to find out the best practices and lessons learned from already happened disasters to improve their disaster management plan. Further, libraries must provide training to their staff as disaster training is an indispensable condition of a disaster management plan and it ensures the efficiency of the plan. The National Institute of Disaster Management (NIDM) in collaboration with other institutes organizes workshops on various aspects of disaster covering every possible

disaster such as earthquake, cyclones, and tsunami. Libraries can register for the workshop and learn from the experts. Additionally, individual efforts can also be taken to train the library staff for any disaster.

With the change in climate and frequent occurrence of natural disasters in the present world, libraries need to shift their focus to draft a disaster management plan according to its need as the libraries serve as the custodian of cultural heritage and bridge the past and future generation through this collection of cultural importance. It is time to emphasize safeguarding its collection and staff as some of the collection can be irreplaceable, and the loss cannot be undone ever. Thus, this study recommends taking the disaster management plan seriously and urges the Indian libraries to draft a disaster management plan. The study also emphasizes the significance of training staff to handle any catastrophic situation and organize mock drills occasionally.

Abstract

Disasters be it natural or humanmade has been perceived from diverse viewpoints in human history. Modern scientific knowledge places enormous emphasis on disaster management, mitigation, resilience, and control, while the field of history and anthropology has focused on various conceptions of disasters and tragedies as experienced and depicted by humans across time and space. The present paper will examine disaster through the lens of indigenous art of the Patuas in India especially their visual depiction of disaster, by combining the methodology of meaning making and indigenous and visual anthropology. The primary objective of the chapter will be to take forward our understanding of disasters not as the common geographical-environmental process but a nuanced, often invisibilized impact they have on human life and imagination of social realities of life, death, spirituality, and religion.

Introduction

Disasters are events which are perceived and experienced differently across humans and communities. It impacts the mind and psychology of human beings, but those close to nature, such as indigenous communities, absorb its occurrence in its most unadulterated form. Some of these human beings who are perceptively sensitive and have an ability to illustrate their experience reflect this impact in their art forms. But this alternative perspective has often been silenced and ignored by modernism, irrespective of its diverse forms. Indigenous art has been subsumed as “primitive” and “tribal.” Art within such an Enlightenment epistemology, was understood as “self-evidently universal,” silencing the histories and achievements of the non-West (Harney and Philips 2018). Following the Enlightenment, modernity played a remarkable role in art with its emphasis on knowledge as what can be “scientifically” tested and verified and not based on religion and myth. Such a definition of “scientificity” rendered indigenous art as mythical and mystic not portraying the “real,” often termed as “primitive” (Price 1989).

It is important to bring to light that in the history of human evolution, art appeared much before writing, which establishes that prehistoric art by humans and indigenous communities is as significant a human contribution to knowledge as philosophical attributions of art and aesthetics in Greek philosophy of Plato and Aristotle.

A dominant tendency among scholars has been to define and measure disaster quantifiably, i.e., in terms of loss of property, life, economic destruction, possessions, etc. Recent development in the field of disaster resilience and studies have focused on the significance of emotional and psychological impact of disaster on humans. A prominent contribution in this newly evolving field of disaster studies is its emphasis on art as therapeutic, possessing healing mechanisms, and how art can bring in hope and recovery from loss (Knoff 2022). Apart from acting as a healing mechanism, it is equally an important tool for expressing stories of disaster, further helping in illustrating experiences of disaster. These experiences reflected through art then gets translated into knowledge that can have impact across boundaries (Alexander 2021: 3,4). Aristotle in his *Poetics* stated that art as mimesis is a natural and pleasant way of learning and contributes to knowledge (Pappas 2013: 18).

The proof of such Eurocentric domination is amply available to be witnessed as none of the so-called handbooks and companions of aesthetics and art carry work on indigenous art and aesthetics or any topic on indigenous knowledge and everyday living such as *The Routledge Companion to Aesthetics* edited by Berys Gaut and Dominic McIver Lopes (2000, 2013) and *The Oxford Handbook of Aesthetics* by Jerryold Levinson (2005).

With this as a background, the present paper elaborates, first art as agency for indigenous communities through a visual anthropological lens and its resistance in the Western epistemologies in Anthropocene and, second, how disasters are perceived by indigenous communities in India and expressed through their art form. The argument of the chapter is supported by the case study of the *Patuas* of West Bengal, also known as *Paitkars*, famous for their indigenous paintings known as *pattachitras* (*Pattachitra* is a Sanskrit term, *Patta* means cloth and *Chitra* means picture. It is a picture painted on a piece of cloth) depicting disasters.

Indigenous Art and Agency

There has been a tendency to hierarchize art into “high” and “low” and “primitive” or “tribal,” forms of art considered much below the high art. Breaking such a hierarchized view of art, Sally Price (1989) asserted that non-Western art must be recognized as it is produced by individual artists through their imagination (Price 1989, as referred in Gell 1998). Moving further, Alfred Gell argued that art of non-Western cultures must not simply be evaluated but identified as possessing a social relation with the community and culture it belongs to. Herein, Gell brings out an anthropological study of art as social relation much beyond its exhibitory-economic value. Gell in his ambitious scholarship to further an anthropological theory of art was one of the pioneering scholars who advocated “art as doing” beyond the usual function of providing meaning and communication (Gell 1998). Nicholas Thomas, in the foreword he wrote for Gell’s book published posthumously, illustrated:

Doing is theorized as agency, a process involving indexes and effects [wherein] indexes are understood as material entities which motivates inferences, responses, and interpretations. Indexes stand in a variety of relations to prototypes, artists, and recipients. Prototypes are the things that indexes represents, recipients are those whom the indexes are taken to effect and artists are responsible for the existence and characteristics of the indexes... [wherein] agency of the artist is rarely self-sufficient but a distributed extension of agent. (Thomas in Gell 1998: xi)

Not only did Gell propounded an anthropological theory of art as agency, but his work is also significant in decolonizing art, especially his challenge to the Western Eurocentric evaluation of any non-Western art with the universal yardsticks of aesthetics. Gell punctures the European project of “indigenous aesthetics” as essentially a project to expand and refine the sensitivities of Western art public, by comparing Western art to non-Western art (Gell 1998: 3).

Art has been understood as agency for individuals and communities; equally art is also a space which is colonized and marred with power dynamics of the market and neoliberal demands. Notwithstanding the approach to art as agency is the acceptance of art as marketable things for the European audience and auctioneers. In this respect, indigenous art or art of Global South had to suffer the onslaught of colonialization and the museumization of their way of life considered as primitive and non-modern, as exhibits in museums for anthropologists to study. Asserting that

colonial mindset not only impacted the art and life of the colonized, Guha Thakurta stated that the museum became a “complex site for production of new orders of religious values” around indigenous art by designating objects of art as “sacred” (Guha Thakurta 2007).

Another significant interpretation of Western epistemologies emanating from the Enlightenment has been the presentation of the indigenous population in various parts of the world as “under perpetual threat,” completely obfuscating their knowledge as premodern, mythic, and spiritual rather than acknowledging that indigenous art and knowledge presents alternative to the dominant white ecological paradigms of thinking about our earth (Horton 2017: 50). Though such thinking has undergone a shift, there still exists a gap among policy-makers and administrative bureaucrats, researchers as well, about indigenous knowledge as “soft” and “unscientific,” incapable of solving modern issues of environmental degradation which modernity itself is responsible for. Indigenous communities do not treat environment as problem but as a part of their life; it is intrinsic to living. From this perspective, indigenous art is not just a thing or piece for collector’s items or antique but as the Cherokee artist Jimmie Durham stated:

“the purpose of art is to help people interpret their world so that they may be better able to change it in positive ways.” In opposition to the kind of privatized vision of art that privileges the individual’s own relationship to his or her work and suggests no desire for any more interactive art process, Durham challenges us to consider how our understanding and engagement with art would change if art were recognized as part of a “social dialogue,” if we could accept art as existing for “the purpose of critical social interpretation.” (Durham as cited in Bell hooks 1994)

For the indigenous communities, their art is about the relationship they share with each other, the cosmos, and nature. It is connected and deeply entrenched in their idea and thought about life and living. It is a social dialogue (hooks 1994). Such renditions of indigenous art and life get either caricatured in their depiction by mainstream cinema and media or canonized as premodern, while what they present is “shared modernity” (Horton 2017: 53). Indigenous art is evolutionary and reactive to the changes in environment. It is neither primitive nor static like the Eurocentric vision shows it to be. Art for the indigenous has also become a political conversation between the humans and nonhumans as Horton also examines the violation of treaties by the American state and the indigenous nations which is often depicted through indigenous art of the First Nations (Horton 2017: 54).

Indigenous Art, Epistemologies, Resistance in the Eurocentric Imposition of Anthropocene

The last decade of the twentieth century saw a new movement in art world, i.e., of connecting art to the idea of the Anthropocene wherein “art is conceptualized as the vehicle of aesthetics, located at the center of thinking with and feeling about the

Anthropocene” (Davis and Turpin 2015: 3). Scholars, especially, anthropologists and art historians, ventured into this space of growing academic discourse focusing on the sensorial and visual in the Anthropocene (*ibid*). According to Davis and Turpin, Anthropocene has brought forth the issue of “living in a damaged world where art provides polyarchic site of experimentation, visualization and new alternates to the Anthropocentric where it is not just a concern, a problem to be managed or mitigated rather bringing in the complexities of power relations which have led to massive transformation of the Earth” (*ibid*: 7). Laura Hall asserted that in thinking about and in the Anthropocene, indigenous art provides a meeting ground for the Eurocentric dichotomies of art and craft, aesthetics and spiritual, as indigenous art is not a part of life but a way of life, rooted in community responsibility and accountability toward living well in the ecologies inherited from their ancestors; such art is capable of renewing fractured cultural-ecological connectivity (Hall 2015: 283).

Postcolonial nations following the path of Western modernity have carried the burden of thinking as “binary”: nature-human and human-artificial; in such ideas, nature seems to be treated as an unlimited credit bank from where humans can simply take more and more. It is such exploitative notions popularized under the tag of “development” that has caused the Anthropocene. In most countries of the African continent, Asia, and Amazonia, agricultural practices of the indigenous communities have been categorically suppressed or discontinued. Indigenous art, although flourished in certain pockets, was not a popular form for many decades in India becoming more lost with meager intergenerational practices, migration of indigenous people to urban centers, and new technologies of art.

Paradoxically, it was the twentieth-century globalization which led to the increasing demand of indigenous art patterns more as fashion and style, while the everyday lives of these communities are getting more marginalized. Parallelly, there are also indigenous creative resistance rooted in the art of healing wherein the aesthetic in indigenous is to “heal” the community from colonial and capitalist violence. But how far the damage of imposing Eurocentric categories and concepts in “making sense” of indigenous can be healed remains a question as the indigenous nations have been categorized by the adulteration of patriarchy, race, and ethnicity, and this has resulted in homogenization of knowledge within the indigenous communities. A case to cite is that of indigenous women. In many countries today, indigenous communities’ identity has been fixated by the state authorities. Critiquing such “misrecognition,” Monika Siebert (2015) argues that multiculturalism with its fetish on recognition is influenced by the Eurocentric liberal perception of what is it to be indigenous. Her work *Indians Playing Indians* (2015) criticizes the cultural misappropriation that multicultural misrecognition has leashed on indigenous nations in a twofold manner: first, by substituting cultural meanings with political meanings of indigeneity and, second, the replacement of “indigenous nations” by the term “indigenous cultures,” equated with the ethnic/immigrant minorities, while they were the original nations and owners of the land and appropriated by the white modern statist powers turning the owners into minorities seeking accommodation and recognition in their own land (Siebert 2015: 3). This in turn has led to the grouping of all indigenous nations under the rubric of “indigenous” without taking

full cognizance of the diversities within these First Nations, another European Enlightenment project of homogenization necessary for the larger interest of the national project of cohesion (*ibid*: 180–181).

Although a complete understanding of indigenous epistemologies may not be comprehensible for non-indigenous individuals and communities, nonetheless, a genuine attempt to shift the focus from a cult of calculative-interpretive result-oriented individuals that modernity has brought with itself to an unfeigned attempt toward accepting an epistemology which believes humans to be nature's extension and not master, acknowledging the earth's healing power, practiced by most indigenous communities may educate us toward acknowledging indigenous epistemologies (Todd 2015). Indigenous worldview is ingrained with the ecological, environmental, or natural world-based knowledge whose inclusion in the Western Eurocentric world continues to be debated till date (Hall 2015: 287). As Battiste and Henderson establish such connections by elaborating that:

Ecological teachings have defined for Indigenous Peoples the meaning of life, our responsibilities, our duties. They have also developed our consciousnesses, our languages, and what others have categorized as our cultures. (Battiste & Henderson, 2000: 9 as quoted in Hall 2015: 286)

Furthering her argument, Hall brings forth the practice of storytelling among the indigenous as a way of reviving, renewing the interconnections with earth as a living being (Hall 2015: 287). This brings us back to our main position of how art becomes a relationship beyond simply an impression or extension of individual emotions, as the pictorial depiction of stories woven in the psyche of younger people by the elder generation. In this respect there is an eerie similarity among almost all indigenous communities irrespective of their location. The Great Andamanese folktales claiming birds as their ancestors (Abbi 2021: 35) are seemingly closer to the “creation stories” of the indigenous people of Canada and North America claiming animals as ancestors (Sengupta 2022).

The indigenous epistemologies have no doubt been influenced by the “quest for political-governmental power forgetting the goal of reconnection and preservation of harmonious ways of life” which has been termed as “internalized colonization” imposed upon indigenous nations (Hall 2015: 288). Yet among the indigenous nations and communities, disasters are not problems to be managed but earth's mode of communication with other living creatures. Such a vision is not control-centric giving way to understanding disasters as “sharing-caring” for the earth and giving time for her renewal.

An Indigenous Understanding of Disasters

Disasters have a special place in traditional knowledge and religion, and indigenous communities offer chants and offerings and conduct ceremonies and thanksgiving in their unique manner (Kapur 2010: 92). To support Kapur's statement, herein quoting

a few examples from the Indian indigenous communities and their age-old practices for perceiving and understanding disasters will clarify the idea. In West Bengal, to avert a threat of flood, women perform a ritual named *Batiphota* (*Batiphota* is a combination of two bangla words – *bati* means a bowl and *phota* means small ball-shaped imprints) wherein the lady who only bears a daughter and not son can perform it. Her daughter is selected by the villagers to recite a few mantras into the bowl, and it is buried under the earth to stop the rain (Kapur 2010: 104,114). Lord Ganesh is termed as *Vighnaharta*, and it is people's belief that by worshipping Lord Ganesh one can not only bring success and prosperity to one's life but also help to deter any disaster to occur on earth. Goddess Kali who is 1 out of 108 avatars of Shakti, *Rakshakali* avatar, is associated with both the destroyer and protector of disaster. People in West Bengal, Orissa, Bihar, and Uttar Pradesh worship Goddess *Kali*. Especially in many villages of West Bengal, *Rakshakali* is worshipped when people are struck by a disaster or epidemic (Scrase 2001: 124).

People living in the Koraput district of Orissa has the presence of huge number of *sacred groves* which according to the villagers would protect them from famine and other epidemic diseases. Deity worship in context to disasters is common in India; the "Naga tribes of Manipur believe that a deity named *Kampinu* made the hills for the Nagas to live in and an earthquake happens when a piece of rock is cut away to mend the deity's house below." In the Himalayas, "the *Gaddi* tribe always carry a sickle which according to them symbolizes the *Kalubir* (the father of all serpent gods). It is their belief that when *Kalubir* is not duly propitiated, a landslide occurs" (Hudson 1911). The Indian Ocean tsunami which struck India on 26th December 2004 was regarded as the outcome of bad sins by many of the survivors. The fishermen who were affected in the coastal areas of India – Kerala, Tamil Nadu, Andhra Pradesh, and Pondicherry – held the belief that it was the "act of god" and the result of displeasure and anger of the sea god due to bad karma. Rituals were performed to satisfy and please Goddess Ganga who is considered to be the goddess of sea and water (Paul 2013).

Along with these religious practices and beliefs, art finds a distinctive flavor within indigenous communities who treat the earth as a living, growing creature. In this way, indigenous art is a repository of knowledge, expression, way of life, and understanding, presenting the events as well as predicting the future events of disasters.

Expressing Disaster in Indigenous Art: The *Patuas* of India

Disasters have found a unique place in popular culture, literature, art, myths, and religion (Giovanni et al. 2019: 12–13). Natural calamities, death, and disease are presented through art of all genres: from rock art in prehistoric period to indigenous art, modern, and postmodern art. The *Patuas*, a community inhabiting the eastern region of India, mainly living in the states of West Bengal, Jharkhand, and Odisha,

are also called as the *Paitkar* and are famous for their scroll paintings known as *pattachitra* (narrative scroll art) accompanied by the songs about the paintings. The *Patuas* are a semi-itinerant caste originally from the village of Naya in West Bengal, and their repertoire of paintings encompasses disasters such as the Medinipur floods, Tsunami, the 9/11 (Korom 2019: 187), and recently the Covid-19 pandemic. Some scholars point out that the *Patuas* belong to the ancient Indian tradition of performing artists, as even the gates of Sanchi stupa, the ceremonial gates of the famous Buddhist pilgrimage (first century BC), have scroll finials depicting life of Buddha, in Jain texts of sixth century BC, and find mention in the *Tarikh-e-Firoz Shahi* 1351–1388 (Sarkar 2016).

The “flood narratives,” as Roma Chatterji calls these paintings, argued that the “the idea of affliction as a form of grace. . . . are performed in the mode of picture storytelling. . . the *Chitrakars*, an itinerant caste of performers, paint and display narrative paintings on a variety of themes inspired by the *mangalkavyas*” (Religious-literary documents, several of the poems also contain references to geographical places and historical events) (Chatterji 2014: 76). The Medinipur floods of 1978 affected Medinipur, bringing havoc and rendering more than two million people homeless, and after the flood water receded, there was fear of epidemic that engulfed the region (Korom 2015).

An interesting feature of the *pattachitra* songs is that the singer mentions the date in accordance with the Saka calendar (The Saka calendar is based on luni-solar reckoning of time consisting of 365 days and 12 months. The calendar was believed to be created by Kushana king Kanishka.) and explains the characters as depicted in the vertical scroll while singing the narrative (Korom 2019: 189). These paintings by the *Patuas* who now call themselves *Chitrakar* (painters) weave in the songs, the narration of suffering, reliefs provided, political gimmicks surrounding disasters, and relief work, all infused through their paintings. This indigenous community of artists uses organic and vegetable colors from nature and does not use chemical colors to draw their *pattachitras*.

In recent times, the young *Patuas* have started small teams which move from place to place informing communities about disasters and how to deal with them. One such group is the *Jubo Shilpogushthi*, who is spreading awareness about the Amphan cyclone, floods, and now the Covid-19 pandemic and the need for hand sanitization, cleanliness, wearing of mask, etc. (Anwar and Akter 2021). The survival of the *Patua* paintings for centuries is the testimony of the community’s resilience and resistance to the surroundings through their art. They fuse the mythological narratives with the contemporary events affecting humans and non-humans equally breaking the binaries of the modernist-humanist, presenting their worldview that all living creatures share this earth in common and disaster affects one and all, rejecting the modern ontologies toward an episteme of respect for nature (Korom 2019: 197). Another scholar Ines Ponte (2015) calls the *Patuas* and their surviving art is a result of cosmopolitan tradition rather than of modernity (Ponte 2015).

Conclusion

Disasters are not what the scientific experts mean and define. It is a polysemous term and its definition, meaning, and understanding are differential. They are not just phenomena to be mitigated using techno-scientific methods, but their perception, mitigation, and response are also subjected to individual/community's understanding and environmental and indigenous knowledge. Disasters are narratives depicted by the artists and painters to describe about the event and educate their community for the future events. Indigenous art plays a critical role in meaning making and interpreting disasters among these communities who have been living in harmony with nature since a longtime. Art be it in a form of painting or performance doesn't always involve words but is rather a reflection of unsaid dialogues. For the indigenous communities, disasters are not problems but rather events to live with and adapt to. It provides an alternative epistemology of disaster events not the capitalistic way of managing and controlling disasters.

Abstract

The twenty-first century is deemed as the century of cities. The rapid and haphazard development of cities worldwide has, however, been faced with unprecedented challenges, ranging from typical concerns like population congestion and pollution to new and emerging risks like pandemics to cyberattacks. In the backdrop of these widespread contemporary challenges, the evolving notions of “smart city” and “resilient city” are now being widely recognized as policy-level pathways for enhancing the quality of life and sustaining urban livelihoods. Although both the visions have considerable overlaps between their meanings and relationships, their ground-level implementation continues to be done in a discrete manner. Recognizing the need for an integrated approach toward smart and resilient cities, this chapter discusses five good practices of smart city developments from around the world (Guwahati, India; Kathmandu, Nepal;

Beijing, China; Surabaya, Indonesia; Takamatsu, Japan), wherein the notion of resilience has been effectively integrated. It is hoped that the lessons derived through these existing cases will provide a broader understanding to researchers worldwide, while also paving the way for policy-level deliberations to realize integrated smart and resilient city development.

Smart city · Resilient city · Information and communication technology · Disaster risk reduction · Integrated approach

Introduction

Attributed to the growing concentration of population and economic activities in cities worldwide, the twenty-first century is widely being recognized as the century of cities. More than 55% of the world's population already resides in cities (confined in about 4% of the terrestrial surface), and this proportion is projected to reach 68% by 2050 (UN DESA, 2019). Serving as the engines of economic growth, cities have been providing ample opportunities for jobs, economic development, and better living standards. However, the continuous migration of people toward cities has, over the years, brought forward many challenges including population congestion, overstressed infrastructure, increased resource demands, increasing pollution levels and waste generation, etc. (Hayat, 2016). Superimposed on these typical challenges are the rising concerns of extreme weather to disease pandemics to cyberattacks. To thrive in face of such unprecedented shocks and stressors, it is increasingly important for the cities to get smarter in risk mitigation while creating livable and self-reliant features.

In that context, to revolutionize the traditional ways of managing urban systems, the fancy notion of "smart cities" has gradually drawn remarkable attention of not only the scientists and policy makers but also the hi-tech businesses. Leveraging the potentials of information and communication technology 'ICT', the idea of smart cities is intended to solve the contemporary urban problems and enhance the quality of life through improved service delivery (Baron, 2012). To date, more than 1000 smart city pilot projects have been executed (are either ready or under progress) worldwide, a few prominent examples of which include San Diego in the United States and Vancouver, Canada (Zhu et al., 2020). Nevertheless, due to the lack of a universally agreed definition (or set of indicators) and the multi-interpretations, the execution of "smart city" concept remains to be challenging. More so, the smart city terminology has developed concomitantly with many other similar terms such as virtual city, intelligent city, ubiquitous city, etc.

While the smart city discourse continues to be debated, the onset of new and emerging risks like the latest COVID-19 pandemic, terrorism, energy crises, and climate change have also mainstreamed the need for new models of governance to enhance the resilience of smart cities. Though the scientific research on smart city

development is increasingly covering wider prospects, Arafah and Winarso (2017) underline that very few of the existing studies have emphasized on the importance of resilience. Besides, the new and evolving concept of “resilient city” has simultaneously attracted global attention for enhancing the capabilities of cities to deal with such unexpected predicaments. Typically, a resilient city resonates with the ability of cities to absorb the impact of the disasters, shocks, and pressures, through adaptation to ensure long-term sustainability of a city’s basic functions. In recent years, numerous researchers (e.g., Shamsi, 2020; Zhu et al., 2020; Sharifi et al., 2021; Majewska et al., 2022) have further conducted in-depth studies on the application of resilient city concept in tandem with smart city solutions, while also uncovering the existing faults, failures, and solutions.

Aimed at realizing sustainable urban development through improved quality of life and the environment, Arafah et al. (2018) underscore that the visions of smart city and resilient city are largely aligned. Earlier, Papa et al. (2015) also underlined their synergies and inconsistencies through a conceptual model. More recently, a variety of research frameworks have also been established to measure the resilience of smart cities and their intricate connections (e.g., Zhu & Li, 2019; Zhu et al., 2019; Zhou et al., 2021). Even as the evolving notions of “smart city” and “resilient city” have considerable overlaps between their meanings and relationships, bulk of the current research is reportedly focused on their discrete application. With an aim to bridge this knowledge gap in their integrated application, this chapter first synthesizes their conceptual evolution independently and then discusses five good practices wherein the essence of concomitantly applying both the notions is clearly reflected.

Broadly, the chapter comprises of five key sections, including section “[Introduction](#).” Sections “[Evolution of “Smart City” Concept](#)” and “[Evolution of “Resilient City” Concept](#)” describe the evolution and characteristics of “smart city” and “resilient city” concepts, respectively. Section “[Integrated Approach Toward “Smart and Resilient City”](#)” discusses five good practices of smart city applications from around the world, wherein the resilience component is duly reflected. Lastly, section “[Key Takeaway Lessons](#)” summarizes the key takeaway lessons.

Evolution of “Smart City” Concept

The roots of “smart city” concept could be traced back to the 1990s, when the term “smart growth” began to be sporadically used in an effort to save the earth, by deriving solutions to rising urban problems such as air pollution, congestion, etc. Arafah and Winarso (2017) specifically highlight the pioneer examples of Singapore and Adelaide smart city, wherein long-term transformations were initiated in 1994 to enhance their ICT infrastructure for better service delivery. Hoelscher (2016) also substantiates that the concept emerged in the late 1990s to early 2000s, from the e-governance movements and collaborations between governments and private companies in Europe and the United States. The early twenty-first century further witnessed the smart city transformation of many European countries, and their upsurge has since then become a global phenomenon (Zhou et al., 2021).

Today, many countries around the world have rolled out pilot projects for developing smart cities, and the notion of technology integration in cities is increasingly being supported and adopted by many institutions. However, as pointed by Hayat (2016), the precise content, features, and nature of smart city developments still vary in different countries, which likely reflects the lack of theoretical consistency. Even though various attempts have been made at conceptualizing smart cities, like through methods of benchmarking and indicator frameworks, the notion of how a city qualifies as “smart” or “not-smart” is still debated. Thus far, numerous definitions have also been put forward by different quarters; however, in reference to Mora et al. (2017), it is clear that the many definitions of smart city are still not coherent, due to which it is difficult to obtain a common understanding. Through an extensive review of more than 100 definitions, the International Telecommunication Union, a specialized agency of the United Nations, established that “A smart sustainable city is an innovative city that uses ICTs and other means to improve quality of life, efficiency of urban operation and services, and competitiveness, while ensuring that it meets the needs of present and future generations with respect to economic, social, environmental as well as cultural aspects.”

Though the precise features of smart city vary widely, Giffinger et al. (2007) pointed out that the concept has six key structuring dimensions: (1) smart economy, (2) smart people, (3) smart environment, (4) smart living, (5) smart governance, and (6) smart mobility. Based on a comprehensive review of existing literature, Khatibi et al. (2021) also summarized several other theoretical dimensions and critical factors of smart city initiatives. Sukhwani et al. (2020) further underline that the current policies of smart city can be categorized in three types, namely, (1) greenfield projects (built from scratch), e.g., Masdar City in Abu Dhabi; (2) purpose-driven SC (industrial city, etc.), e.g., Songdo International Business District (South Korea); and (3) brownfield projects (by retrofitting existing cities), e.g., Amsterdam (The Netherlands).

Evolution of “Resilient City” Concept

Originally introduced by C.S. Holling in 1973 (Holling, 1973), in the context of engineering and ecological sciences, the concept of resilience is referred to as the ability of a system to absorb any changes and its capacity for reorganization or adaptation in face of disruptions. Gradually, the concept has also been adopted in disaster science, development planning, economy, social psychology, and many other fields. Particularly, in context of cities, the term resilience is referred to as the ability of individuals, communities, institutions, businesses, and systems within a city to adapt and respond (or their ability to “bounce back”) to any changes and disruptions (for further reading, Patel & Nosal, 2017; Arafah et al., 2018; Khatibi et al., 2021; Yang et al., 2021). Cartalis (2014) provides an extensive overview of definitions, challenges, and prospects associated with “resilient city” ideology, while emphasizing that cities must have the strength to resist any acute shocks (such as earthquakes, floods) and chronic stresses (such as food and water shortage), along

with the flexibility to accommodate extreme situations and the capacity to recover quickly. For the design and planning of resilient cities, several key principles have also been recognized, such as redundancy, robustness, resourcefulness, flexibility, adaptability, etc. (OECD, 2016).

Different meanings of resilient cities have been discussed since the 1990s (e.g., Pickett et al., 1992); however, the ideology has received wider recognition after the start of twenty-first century and is today being explicitly acknowledged at global policy levels (Patel & Nosal, 2017). Khatibi et al. (2021) highlight that about 2100 cities all over the world have joined the “Making Cities Resilient” initiative (that was launched in 2010). Furthermore, 100 cities have also been selected under the 100 Resilient Cities (100RC) initiative that was launched by the Rockefeller Foundation in 2013. Notably, 100RC is established as a nonprofit organization dedicated to providing financial and technical support to cities around the world, with an objective to realize resilient cities in face of contemporary challenges (100 Resilient Cities, 2019). The organization brings together cities, experts, and other multi-stakeholder groups through its platform partners, while sponsoring a Chief Resilience Officer and facilitating the development of City Resilience Strategy. Hofmann (2021) details the overall process of city selection, strategy development, and stakeholder engagement under this program. To guide the selected cities, the Rockefeller Foundation along with ARUP (a global design firm) has developed a set of tools (City Resilience Framework and City Resilience Index) that allow cities to analyze and assess their resilience (for further reading, Galderisi et al., 2020). Although the program ended in 2019, Hofmann (2021) highlights that it still continues to work toward lesson sharing through its successor, Adrienne Arsht Center for Resilience.

Today, in the age of COVID-19, the notion of resilience has become a guiding component for cities worldwide, and the need for realizing “resilient cities” is more than ever. DeVerteuil et al. (2021) also emphasize that the discourse around “resilient city” is gaining fast traction, as it recognizes the importance of absorbing, attenuating, and surviving any crisis, rather than ambitiously aiming for warding it off or eliminating it.

Integrated Approach Toward “Smart and Resilient City”

Evident through sections “[Evolution of “Smart City” Concept](#)” and “[Evolution of “Resilient City” Concept](#),” just like the notion of smart city, the quest for resilient city is also not new. City governments around the world have for long been working to discretely apply both these ideologies to address the diverse urbanization-related problems. However, in view of their shared essence, a genuine need has now been recognized for an integrated approach toward execution of both these identical development paradigms. Particularly after the sudden outbreak of the coronavirus disease from Wuhan (COVID-19) in January 2020, when several modern and smart cities across the world (like Wuhan, Auckland, London) were faced with lockdowns and its grave social, economic, and environmental consequences, the resultant disruptions in city operation worldwide were a clear manifestation of insufficient

urban resilience. Even though the ongoing smart city developments have increased the adoption of data sensors and automation technologies in managing urban systems, it is evident that the new and emerging risks still pose challenges for the continuity of services (Zhu et al., 2020). At the same time, through the conduct of 100RC program, several shortcomings have also been observed in the execution of “resilient city” concept, as the goals of resiliency building in the partner cities are still not fully accomplished (Hofmann, 2021). With a core realization that concomitant actions are needed to make cities resilient while approaching toward smart cities and vice versa, this section mainly presents five good practices from around the world, wherein the smart city developments have effectively incorporated resilience components.

Case of Guwahati, India

In June 2015, the Government of India launched the “Smart Cities Mission” (SCM) for developing 100 smart cities across the country, with an allocated funding of around 700 million US dollars (USD) for the initial 5 years. Selected based on a rigorous two-stage competition at intrastate and interstate levels, the selected 100 cities represent all Indian states, based on a combination of population and a range of governance indicators. For the selection process, each candidate city was required to prepare a smart city proposal (SCP) that outlines their suitability for SCM. Herein, the proposal guidelines mandated to follow an area-based approach (like for upgrading certain areas through retrofitting) while also including pan-city elements (for further reading, Hoelscher, 2016; Sukhwani et al., 2020).

Guwahati, the capital city of Assam State in India, has also been selected for the coveted SCM project. Situated on the banks of River Brahmaputra, Guwahati nurtures great biodiversity and is blessed with a natural topography comprising hills, lakes, wetlands, and streams (Hemani & Das, 2016). A fast-growing metropolis, Guwahati also serves as a hub for fostering “Look East Policy” of India due to its strategic geographic location. The exponential population growth and the haphazard urbanization in recent years have, however, degraded the city’s natural ecosystem, and there is enormous pressure on availability of land and infrastructure. Located on an earthquake-prone belt, the region has also started to frequently experience landslides and flash floods, which is largely attributed to land use change (Deka & Devi, 2017).

Taking due account of the city’s rich cultural and environmental heritage alongside the existing vulnerabilities, the SCP of Guwahati (Guwahati, 2016) leverages the locational advantage of city to enhance its prospects in terms of tourism, business, trade, education, and health, while aiming to achieve a climate-resilient and flood-resilient city. Correspondingly, the SCP of Guwahati enlists several eco-friendly projects aimed at redesigning the ecological public realm of the city, like, for instance, networking the open spaces to stimulate rainwater harvesting, developing basin-specific stormwater management plan along with open space master plan, exploring eco-mobility options along stormwater drains, etc. As part

of the area-based approach, retrofitting of around 696 acres of continuously placed water bodies is planned to be taken up along with the development of 6 km long riverfront development, with an objective to mitigate floods and reconnect the city to its riverine systems. Herein, eco-restoration and bioremediation techniques are also being explored to realize landscape transformation of the degrading water bodies. Further, as part of the pan-city approach, ICT-based applications (sensor networks, CCTV surveillance) are also being operationalized across Guwahati City to offer a series of services to citizens for monitoring water resources information along with advanced flood warning systems and other services such as for traffic management.

The projects listed in the smart city action plan of Guwahati clearly reflect how smart city developments can closely be aligned with the goals of resilience building. While the smart city developments are recognized for ICT implementation to enhance service delivery and to boost economic growth, Guwahati City has been laying high emphasis on utilizing the technological advancements for mitigating the existing vulnerabilities.

Case of Kathmandu, Nepal

Typical to the South Asian context, Nepal is one of the most disaster-prone countries in the world (UNDRR, 2019), and Kathmandu Valley (capital valley) is one of the most earthquake-prone cities (GFDRR, 2017). As per the census of 2011, the urban population in Nepal increased by 58.38% as compared to a decade earlier, and the census of 2021 is very likely to confirm a similar trend in the last decade. Besides, the development of new roads and better service delivery at local level has supported the continual development of new towns and cities. While the government agencies in Nepal have successfully pooled the required lands, built the foundational infrastructure (sewage, drainage, roads, piped water supply, open spaces, public transportation, IT infrastructure, etc.), and established a handful of townships that cater basic services to the population, majority of these urban centers still do not have even the basic physical and social infrastructure and government services.

In context of smart cities, Nepal does not have a standardized commonly accepted definition. However, two attempts have previously been made by government agencies to define smart cities as follows: (1) In July 2016, the National Planning Commission of the Government of Nepal has developed a “Smart City Concept Note” (NPC, 2016); and (2) the Department of Urban Development and Building Construction (DUDBC, a federal government agency) has published the “Final Report: Preparation of Concept and Indicators for Smart Cities in Nepal.” Correspondingly, there are two approaches to smart cities: (1) fix or renovate existing infrastructure and services such as transportation, water and electricity supply, sewage, etc., by using off-the-shelf technologies to make the systems more efficient and predictable, and (2) build a whole new urban environment using the latest information technologies, sensors, robotics, and auto-control configurations, along with risk-sensitive urban planning. According to DUDBC, in Nepal, 13 smart cities plans are presently in the process of development.

Kathmandu Valley is recognized to be a potential candidate for smart city transformation in Nepal. It has 21 municipalities, including 2 metropolitan cities of Kathmandu and Lalitpur. Kathmandu Valley is one of the most at-risk cities in the world in terms of earthquake and fire risks. Furthermore, since 2016, Kathmandu Valley has witnessed floods every monsoon season. Kathmandu Valley Development Authority (KVDA) is a government agency that has the mandate to plan and implement development projects within Kathmandu Valley. In this context, the KVDA has entered a MOU with Oriental Consultants, a Japanese consulting private company, for development of four smart cities in Kathmandu Valley (OCG, 2020). While project-specific activities under the smart city projects are being designed and yet to be implemented on the ground, the government is already taking some good initiations toward making a city smart and lower disaster risks. For example, laying of underground electricity and Internet cables in Kathmandu Valley has not only improved beautification of the city, but it has also drastically lowered fire risks in the aftermath of an earthquake. There are clear benefits of moving toward smart cities by adopting ICT and AI in some service components and gradually expanding to other services, particularly from disaster risk management and resilience perspective. In that manner, the development of smart cities will be an evolutionary process in Nepal, and so will the process of managing urban disaster risks.

Case of Beijing, China

For long, the Government of China has been devoting to the promotion of smart cities, and China is recognized to be one of the first developing countries to have started the smart city planning. In 2012, the Government of China identified 90 cities as a pilot project for smart city planning, which also included Beijing, the capital of China. As one of the biggest cities in China, the number of residents in Beijing was over 21 million in 2020. From 2010 to 2020, the city has been witnessing an average population increase of 1.1% per year (Beijing Municipal Government, 2021). The consequently increasing burden on public services has resulted in increased incidents of traffic jam, low efficient public management, and other social problems.

Since 2012, the municipal government in Beijing has been operationalizing a unique smart city system, which has been supported by the rapid development of Internet economy in China. In that regard, the key characteristic of smart city system of Beijing is that the municipal government is aiming at establishing a highly efficient public service and governance system. In public service domain, the municipal government has established an online public service platform application, called as Beijingpass, through which most kinds of administrative procedures could be finished online without waiting for long (Beijing Youth, 2021), such as the social security procedures and the vehicle procedures. In the future, the Beijingpass is expected to be further integrated with many other public services based on big data sharing. In governance domain, the municipal government of Beijing is also trying to realize open governance through quick-photo platform (Beijing Daily, 2021). At present, the open governance platform has been applied in traffic governance and

related infrastructure, wherein all registers could take a photo, like, for instance, when found breaking a traffic signal, etc. In the future, more open-access platforms are to be applied to improve the governance efficiency.

More recently, the disaster prevention and disaster risk reduction factors have also come into the sight of the Beijing Municipal Government as extreme weather events are getting more frequent, especially the heavy rainfall events (like in July 2021) that have caused enormous damage to city. Accordingly, the municipal government has been working on the integration of emergency management system. The weather data and geological data collected by different departments will be shared with the emergency management department to improve the disaster risk reduction system of Beijing, especially the early warning system (Beijing Youth, 2021). In the future, open governance platform is also expected to be integrated with the emergency management system to accelerate the recovery from damages of extreme weather.

Case of Surabaya, Indonesia

Indonesia is one of the most disaster-prone countries in the world, with exposure to several hazards including floods, landslides, droughts, tsunamis, earthquakes, volcanoes, and forest fires. Often, the poor and vulnerable population in Indonesia have to bear the disproportionate burden of disaster impacts due to their lack of access to key services, limited assets, and lack of financial resources (Stanton-Geddes & Vun, 2019). In that backdrop, since 2017, the Ministry of Communication and Information Technology in Indonesia has been implementing a pilot project for the Smart City Movement, with a goal of achieving 100 smart cities with advanced technology features by 2020. The implementation of smart city in each of the selected cities, however, is determined by how the local administration adapts the idea to local features (Devega in, Syalianda & Kusumastuti, 2021). The Surabaya City government, being led by the City Mayor, is the key policy implementer in realizing the Surabaya smart city, while other government agencies are also engaged at various levels (Pangestu et al., 2021).

In Indonesia, the term smart city was first popularized in 2011, when the City of Surabaya won the Smart City Award (at the national level) for three categories, namely, Smart Governance, Smart Living, and Smart Environment (Setiaji, 2018). Surabaya won the award for smart environment because of its efficient early warning system for disasters, ICT-based trash management system, and ICT-based water monitoring system (Pangestu et al., 2021). Notably, the early warning system implemented in the city, named the Surabaya Early Warning System (SEARS), is particularly intended to support urban disaster resilience.

Further, to collect disaster data, the private sector from NATEK Studio has developed the Matakota application, which assists the Surabaya government toward smart city implementation. This application has six reporting functions, namely, traffic, disaster, criminal, fire, social, and child protection. It also provides a panic button to get a quick response from the relevant agencies in emergency situation. Matakota application further helps to enhance cooperation between several city

government agencies such as hospitals, fire departments, etc., to follow up on emergency reports. Remarkably, to avoid fake panic buttons, the application has been integrated with the Population Identification Number (NIK) which is issued by Population and Civil Registry Office (Andarningtyas, 2017). In its development, the Matakota application will be integrated with CCTV, drones, and IoT systems, through which it can access images at certain locations in real time to monitor traffic jams. The Matakota application is also very helpful for the local community of Surabaya to report disaster events to the relevant agencies, while it also helps the government to speed up its emergency response. Apart from the e-government platform, the Surabaya City government is also using Matakota to lay emphasis toward capacity building. Moreover, this application also helps to disseminate government information to the wider community in Surabaya, be it the case of its early warnings about disasters or the latest news in Surabaya.

Case of Takamatsu, Japan

While the national government of Japan published its first official document to promote smart city developments in 2018, the smart city construction in Japan has begun much later than other developed countries (MLIT, 2018). Still, some cities have already developed their unique smart city systems based on their local conditions and local problems. For instance, the Takamatsu City in Kagawa Prefecture has been facing the problems of aging society and declining population (like many other areas in Japan) and vulnerability to natural hazards. The city has correspondingly been working to establish a smart city system (based on IoT platform) with nearby cities and villages. There are two key characteristics of this system: First, it does not only focus on a single city, but a central city with small cities and villages nearby. Second, this system is disaster risk reduction-oriented system, as it is designed to collect and share the data of infrastructure to improve the disaster risk reduction system. The reason for this unique system is that one city cannot afford the high cost of a IoT platform, since the revenue of local government in Takamatsu (and also other cities in Kagawa Prefecture) has constantly been decreasing due to the demographic changes in recent years (Takamatsu Municipal Government, 2018). On the other hand, as the central city in this area, most of the residents in other small cities and villages must work or study in Takamatsu City, due to which a comprehensive data collection ability and information sharing system is necessary for Takamatsu City (Cabinet office, 2020). It is also relevant because of the fact that Kagawa Prefecture is facing a high risk of natural hazards such as trough earthquake and extreme weather events like heavy rainfall.

Moreover, the smart city system of Takamatsu City has also realized the integration of traffic data, route condition, water-level data and rainfall by connecting water-level sensors, meteorological facilities, road camera to Internet, and the application of IoT. Today, the central city, small cities, towns, and villages could check the same information in the same interface. Through this network connection, the Takamatsu City could send an early warning to high-risk areas, and the central city could

simultaneously prepare early for the rescue and recovery based on the accurate data to improve the disaster resilience of this area.

As climate change is also considered as one of the main problems in DRR 4.0 (Cabinet Office, 2017), the smart city system model of Takamatsu City can serve as a good reference to other prefectures in Japan and cities worldwide that are also facing the similar problem.

Key Takeaway Lessons

Each of the five cases of smart city developments, discussed in section “[Integrated Approach Toward “Smart and Resilient City”](#),” have unique characteristics. From context-specific objectives to key focus areas, significant variations are notable in how the smart cities are being executed. For instance, the SCM project of India is being executed with a combination of area-based and pan-city approach, while in the case of Nepal, the theoretical understanding about the smart cities is still in development. Japan, being a developed country, has started to focus on smart city application at a later stage, while China has for long been devoting attention to it. Moreover, in each of the five cases, we have also observed different focus areas ranging from ICT-based advancements for improved service delivery, e-governance systems, ICT-based environmental management, etc. One key point reflected through all five cases has been the consideration of resilience factors. For instance, in case of Guwahati (India), the existing flood vulnerabilities have duly been addressed in the smart city planning, while in the case of Takamatsu (Japan), due emphasis has been laid on enhancing regional-level urban-rural connections to overcome the demographic challenges. Deriving lessons through these good practices, the following subsections summarize the key takeaway lessons for creating smart and resilient cities.

Toward Integrated “Smart and Resilient City” Concept

Both “smart city” and “resilient city” are contemporary concepts, which have evolved over the last 20 years as strategic solutions to sustain urban livelihoods against the varied challenges associated with rapid urbanization, urban population growth, changing climate, etc. While the concept of smart city relies on the rollout of ICT to boost economic growth and enhance quality of life, the notion of resilient city intends to enhance the ability of cities to prepare well against any catastrophic event. Moving toward a common goal for urban sustainability, Tzioutziou and Xenidis (2021) underline that further deliberations and research on the operational foundations of “smart city” and “resilient city” concepts can support the development of an integrated framework. Today, as the resilience discourse is embracing broader dimensions with technological consideration, the smart city interventions are also encompassing the perspectives of disaster risk reduction.

Although there is an agreed notion that a smart city must prepare to be resilient to deal with unexpected predicaments, the integration of resilience component with the smart city approach, however, is still abstract and vice versa. Despite the everyday use of “smart city” and “resilient city” concepts in urban discourse, their universal interpretation is still not formalized (also highlighted in section “[Introduction](#)”), and their multifaceted definitions further make it difficult to concisely capture their key features in an integrated framework. Regardless, a growing number of theoretical and operational studies are today employing these two concepts together, and the resilience of smart cities has become a prominent topic. For instance, Zhu et al. (2019) conducted an empirical investigation to investigate the resilience of 187 smart cities in China.

While the traditional disaster management systems are faced with the lack of effective means to collect, integrate, and process large volumes of data from multiple sources in real time, the recent technology advancements (like the Internet of Things and big data analytics) are also providing innovative opportunities for effective development of disaster-resilient smart city environment, as pointed out by Shah et al. (2019). Today, ICTs can provide an enabling environment for generating multidimensional data through heterogeneous data sources that can help derive quick and timely situational awareness, eventually enhancing the preparedness and response to any emergency.

Relevance of Soft Assets in Creating Smart and Resilient Cities

To achieve smart and resilient city objectives, soft or nonphysical assets also play an important role, as a capital component, for enabling a city to deliver and mainstream a people-centered policy in addition to the benefits provided by traditional, hard infrastructure. In general, soft assets involve social and human capital, knowledge, technology/information, participation, external relations, and innovative approaches that drive value in city (Wataya & Shaw, 2019). Wataya and Shaw (2022) emphasize that hard assets alone do not define a city and it is the participation of people that is vital. Considering this dichotomy between hardware and software approaches as well as blended options, cities need to be smart, lean, integrated, cost-effective, and resource-efficient. While each city has their own values, approaches, and objectives, such soft assets enable a city to develop smarter solutions and more resilience by spillover or scaling-up spreading results throughout city or a community. A balance of both hard and soft assets should therefore be considered and used in the municipal decision-making process. There are different ways to incorporate soft assets to achieve smart and resilient city objectives, three of which are as explained below.

Fundamental Level in Society

According to Resilience Alliance (2022), “Resilience is the capacity of a social-ecological system to absorb or withstand perturbations and other stressors such that the system remains within the same regime, essentially maintaining its structure and functions. It describes the degree to which the system is capable of self-organization,

learning and adaptation.” From the sociological perspective, key soft assets are people/human and institutional capital and competencies that demonstrate the technical, operational knowledge, planning, and institutional capacity to create robust social systems and organizational structure.

Increasing Rapidity at City Level

When facing external risks, the capacity of a smart and resilient city to prioritize needs and implement recovery actions requires utilization of both soft assets and hard infrastructure. It is important to achieve resilience at a local level. UNISDR defines a resilient city as a city capable to withstand or absorb the impact of the hazards, shocks, and stresses through adaptation or transformation, in order to guarantee long-term sustainability, as well as its basic functions, characteristics, and structures (UNISDR, 2012). Capacity through adaptation or transformation is achieved by repetitive learning process and growth from lessons and experiences from past incidents. The learning perspective is one of the key components of the value creation framework for the public sector (Kaplan & Bower, 1999). It can provide improvements in internal capacity for better implementation, results, and stronger resilience outcomes.

Adaptation and Transformation at Community Level

Repetitive learning and this growth process develop the capacity to adapt and transform. Norris et al. (2008) emphasized this: “community resilience emerges from a set of capacities – community resilience from a set of networked adaptive capacities. This is an important point: resilience rests on both the resources themselves and the dynamic attributes of those resources (robustness, redundancy, rapidity).” Therefore, adaptive capacities consist of a set of networked resources, i.e., economic development, social capital, information, communication, and community competencies.

Moreover, the value and impact created by soft assets (spillover, scaling-up, etc.) are basically unpredictable and difficult to quantify. This unpredictability creates a sense of “risk of the benefit of spillover” (unanticipated benefit) for decision-makers. As Haskell and Westlake (2018) point out, an unknown risk of spillover or scaling-up benefits can be a disincentive for investors employing soft assets. This resistance is particularly applicable to the public sector. Municipal authorities need to demonstrate performance to citizens (taxpayers). Also, authorities may be limited in their ability to leverage the features of soft assets because of strong bureaucratic structures or silo culture within their operations. It is a major challenge to introduce innovation breaking through entrenched bureaucratic silos to create a new pathway for a beneficial holistic approach. Because of the demonstrated value addition of soft assets, local authority decision-makers therefore need to find evidence-based support for realizing the objectives and vision of smart and resilient cities, thereby benefitting its citizens.

Acknowledgments The first author (V.S.) is thankful to the Ministry of Education, Culture, Sports, Science and Technology (MEXT), Japan, for the provided scholarship.

Abstract

Communication holds the key to an efficient disaster management. The aims of crisis communication broadly, is to inform, educate and communicate with various stakeholders with a view to create resilience and confidence among them and communities at large. The people in charge of communication need to be trained specifically in communicating on disasters during various stages, viz., pre-disaster, disaster and post-disaster. Among the various stakeholders who need to be sensitized and trained, the most crucial include, the civil servants, who are called upon to administer/manage disasters, the information public relations personnel in the central and state governments who disseminate information to the media on behalf of the government, disaster management teams at ground zero and at head office level, the communities at the grassroots level and last but not the least the media persons who need to be exposed and sensitized to the disaster management emergency response system and the preparedness of the administration in dealing with any kind of situation so that their reportage is balanced.

J. Jethwaney (✉)
NAPSIPAG Center for Disaster Research, New Delhi, India

It is generally believed that truth is an easy causality during a crisis. Therefore, it is important that efforts be made to disallow the formation of grapevine, misinformation and fake news. Media often takes the centre stage post a disaster. The news media by its nature is critical of those who are in charge of disaster management to find the underlying cause of the tragedy. Misinformation, disinformation and scare mongering during disasters is a common occurrence; therefore, managing perceptions is important to ensure that the situation does not get out of hand. In the smart cities' context, it is expected that these are equipped with zero-failure communication dissemination apparatus and mechanism.

The chapter would explore the multi-pronged challenges in disaster management but most importantly how the people in charge of disaster management and communication are to be trained to do a professional job. The chapter would provide an outline of the training contents on disaster communication for various stakeholders.

Keywords

Accountability Crisis · Disaster · Knowledge -sharing · Management · Leadership · Media Training · Stakeholders · Strategic communication

Images of disasters both natural and man-made, the mushroom-shaped smoke in the aftermath of the dropping of atom bombs in Hiroshima and Nagasaki, the soul-stirring shots from the Chernobyl and Fukushima disasters reflecting human suffering, but at the same time resilience of the communities, the mayhem left by the Tsunami, the lethal Bhopal Gas Tragedy, pictures of hapless people, the blood and gore in the aftermath of wars and natural disasters, and the trauma and despondence of the survivors looking askance, remain etched in public memory for long. Media an effective chronicler of events, though not necessarily always objective, has brought disasters live in our living rooms thus making everyone a part of the multiple act of the tragic drama, every time a disaster strikes. Journalism as put by the *Washington Post* President and Publisher Philip L. Graham is “the first rough draft of history.” The Internet has ensured that what is uploaded once, its footprints remain permanently, underlining the importance of media and communication. The role and scope of communication and independent news media, therefore, as areas of inclusion in the disaster policies and laws in various countries cannot be underestimated.

Disaster as a Subject of Study

Disaster as a subject of study is not very old. The last few decades have seen disaster management being included as an area of academic study in some universities. Disasters can be defined as “severe alterations in the normal functioning of a community or a society due to hazardous physical events interacting with vulnerable

social conditions, leading to widespread adverse human, material, economic, or environmental effects that require immediate emergency response to satisfy critical human needs and that may require external support for recovery” (https://www.ipcc.ch/site/assets/uploads/2018/03/SREX-Chap1_FINAL-1.pdf). Disaster management largely refers to the systematic organization and management of institutional roles and responsibilities in dealing with emergencies (Quarantelli, 1988).

The United Nations General Assembly declared the decade of 1990s as the International Decade of Disaster Reduction (IDNDR) with an overarching aim to “decrease the loss of life, property destruction and social and economic disruption caused by natural disasters such as earthquakes, tsunamis, floods, landslides, volcanic eruptions, droughts, locust infestations, and other disasters of natural origin.” This happened after the adoption of Resolution 44/236 on 22 December 1989. To support activities of the decade, a Secretariat was created in Geneva in close association with the UNDRO (https://www.un.org/ga/search/view_doc.asp?symbol=A/RES/44/236). The first archived international assistance in disaster management is ascribed to the Red Cross which provided relief to the war affected in the Battle of Solferino in 1859. Red Cross was founded by J.H. Durant, a Swiss Philanthropist and Humanitarian in 1863 in Geneva. (<https://www.nobelprize.org/prizes/peace/1901/durant/facts/>) Now there are several international agencies and private charities that come forward and provide the needed resources to the extent possible.

Disaster Management Initiatives

Vulnerability to natural and man-made disasters varies, depending on their geographical location and preparedness in handling various kinds of disasters. Disaster management requires the active contribution of various stakeholders including communities and media, but the disaster plans of most countries do not necessarily incorporate the role of these stakeholders in full measure, especially the media. One has witnessed a lot of academic debates and research in the arena, but regrettably, the people in general, who bear the brunt of disasters may be ill-prepared in dealing with disasters when faced, rendering all the serious work done by experts to question. Capacity building and public information campaigns on disaster preparedness still remain a distant dream, even in some of the most disaster-vulnerable countries.

In the next few paras, we shall look at some of the policies and laws in a cross-section of countries that are vulnerable to disasters, to argue how important it is for the lawmakers to appreciate and include the importance of including media and communication in the overall disaster management plans and execution.

Bangladesh

Owing to its geographic location, Bangladesh is very vulnerable to natural disasters like floods, earthquakes, cyclones, droughts, Tsunamis, lightning, river bank erosion, and arsenic contamination, besides man-made and health emergencies. Bangladesh

passed a law on disaster management in 2012. Later the National Planning Disaster Management (NDPM) for 2016–20 was prepared to “guide implementation of the Disaster Management Act 2012, allowing GoB ministries and other agencies to use it to produce their Annual Work Plans. The plan takes a ‘whole-of-Government’ approach, and it also attaches importance to engagement of the private sector” ([https://modmr.portal.gov.bd/sites/default/files/files/modmr.portal.gov.bd/policies/0a654dce_9456_46ad_b5c4_15ddfd8c4c0d/NPDM\(2016-2020\)%20-Final.pdf](https://modmr.portal.gov.bd/sites/default/files/files/modmr.portal.gov.bd/policies/0a654dce_9456_46ad_b5c4_15ddfd8c4c0d/NPDM(2016-2020)%20-Final.pdf)).

The Disaster Management Act 2012 provides the legal framework. The prime minister heads the National Disaster Management Council, which is the “supreme body for providing overall direction for DM.” The Ministry of Disaster Management functions as the secretariat to NDMC. The plan has three core goals, viz., Saving lives; Protecting investments; and Effective recovery and rebuilding. Interestingly in the NPDM, there is no mention of the role, scope, or use of news media as an institution in disaster management. In the yearly plans from 2016 to 2020, there is a mention of “creating awareness,” which can be deduced as information dissemination from the government’s end.

People in Bangladesh especially those residing in the interiors and cyclone-prone areas depend a great deal on warnings from the radio. The state-run radio called the *Bangladesh Betar* with six stations and ten relay stations covers the entire length and breadth of the country. Similarly, Bangladesh Television with two stations and 13 relay stations covers over 90 percent national territory as an empirical study (Shahidul Islam et al., 2004).

India

India has been a witness to many natural and man-made disasters from time to time. The commonly occurring disasters include earthquakes, lightning, floods, landslides, gas leakages, and caving in of tunnels at coal mines, among others including Tsunami and industrial disasters. The Disaster Management Act (DMA), 2005, defines disaster as “a catastrophe, mishap, calamity or grave occurrence in any area, arising from natural or man-made causes.” The Act also defines disaster management as “a continuous and integrated process of planning, organizing, coordinating and implementing measures” (https://ndma.gov.in/Reference_Material/DMAct2005).

The DMA has mentioned about media interestingly in section 67 and circuitously also in section 54. First, let us look at section 67:

67. Direction to media for communication of warnings, etc. – The National Authority, the State Authority, or a District Authority may recommend to the Government to give direction to any authority or person in control of any audio or audio-visual media or such other means of communication as may be available to carry any warning or advisories regarding any threatening disaster situation or disaster, and the said means of communication and media as designated shall comply with such direction.

Clause 54 defines the punishment for “false Warning” thus:

“54. Punishment for false warning. – Whoever makes or circulates a false alarm or warning as to disaster or its severity or magnitude, leading to panic, shall on conviction, be punishable with imprisonment which may extend to one year or with fine.” Although “whoever” has been left ambiguous, it could be interpreted to include any person or any institution including news media and social media platforms.

News media, as we see in both the sections, is seen as a tool, as a medium, and not as a stakeholder or an independent interpreter of events. The reference is also in the way of instructions under clause 67 and a warning under clause 54.

Acts and Laws on Spreading False Information

Section 505(1) of Indian Penal Code, 1860: The punishment for making, publishing or circulating any statement, rumour or report which may cause fear or alarm to the public, or to any section of the public.

Punishment: Imprisonment which may extend to 3 years or fine or both.

Section 66D of Information Technology Act: Whoever, by means for any communication device or computer resource cheats by personating.

Punishment: imprisonment of either description for a term which may extend to three years and shall also be liable to fine which may extend to one lakh rupees.

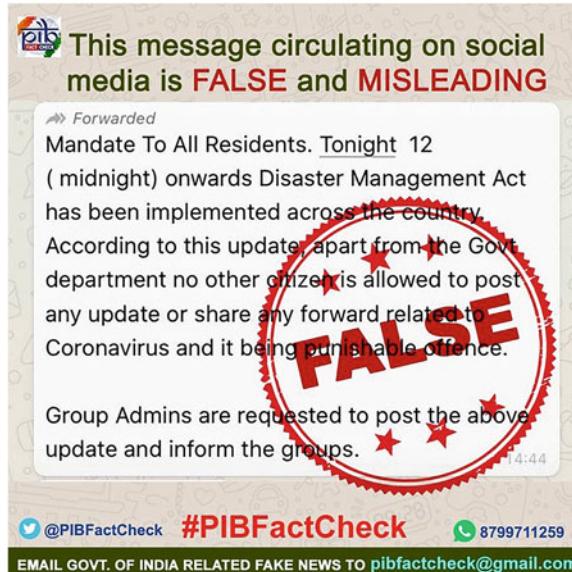

Section 54 of the Disaster Management Act, 2005: Whoever makes or circulates a false alarm or warning as to disaster or its severity or magnitude, leading to panic.

Punishment: Imprisonment which may extend to one year or with fine. (https://economictimes.indiatimes.com/news/politics-and-nation/view-disinformation-in-times-of-a-pandemic-and-the-laws-around-it/articleshow/74960629.cms?utm_source=contentofinterest&utm_medium=text&utm_campaign=cppst)

For long, disaster plan standard operating procedures (SOPs) often have not specifically mentioned the role and scope of independent news media and communication. By its protocol default, the news media does acquire center stage as they are in the business of news, and there cannot be a more urgent time for the media to share the “breaking news” than a disaster.

The Covid-19 pandemic was put under the DMA, in 2005 by the central government and notified to the public. The unprecedented crisis saw the emergence of grapevine, gossip mongering, and false information on various social media platforms. Through social media platforms, a rumor floated that only the government of India would publish and share information on Covid-19 and not anybody else. The Government realized the mischief by some and immediately got into action through its Press Information Bureau (PIB), immediately clarifying its stand, using various

media platforms including the social media as reflected in the graphic below (Source: https://twitter.com/PIBFactCheck/status/1245643028951228416?ref_src=twsrc%5Etfw%7Ctwcamp%5Etweetembed%7Ctwterm%5E1245643028951228416%7Ctwgr%5E%7Ctwcon%5Es1_&ref_url=https%3A%2F%2Fthelogicalindian.com%2Ffact-check%2Fdisaster-management-act-coronavirus-supreme-court-20523).

The mainstream media wrote about this phenomenon immediately. Online news portal, The Print said, “Circulating fake news on Covid-19 during the 21-day ‘complete lockdown’ announced by Prime Minister Narendra Modi Tuesday can lead to a trial, and punishment of up to one-year imprisonment” (<https://theprint.in/india/spreading-fake-news-rumours-on-covid-19-can-land-you-in-jail-for-a-year/387611/>).

Media also carried stories about some journalists getting booked by the police for spreading “Fake News.” Both the DMA and the hackneyed, Epidemic Diseases Act, 1897, were invoked to arrest journalists. Media reported that the Assam government had constituted a five-member committee “for monitoring and checking of fake news in all forms of media” (<https://www.hindustantimes.com/india-news/about-500-cases-lodged-in-india-for-social-media-posts-on-covid-19/story-PBaxt7oNs9IdPNUCVRiUUM.html>). The Indian Express reported that 14 FIRs were filed against five journalists from Himachal Pradesh, some for showing live coverage of migrant laborers on reverse migration (<https://indianexpress.com/article/india/14-firs-five-reporters-himachal-fake-news-disaster-management-act-6412057/>). The news story shared that a multiple acts were invoked in almost all these cases.

Section 54 of the Disaster Management Act, which prescribes a penalty for false alarm leading to panic, was invoked in a majority of the 14 FIRs. Section 188 of the Indian Penal Code that relates to disobedience to order duly promulgated by a public

servant was invoked in almost all of the FIRs. The story quoted Mohan Lal Verma, a member of the Shimla-based Working Journalists' Association, who called the journalists frontline warriors in the COVID crisis, questioned the action taken by the authorities, reasoning that "Instead of registering FIRs, they should be assured medical compensation in case of contracting the disease" (Ibid).

Japan

Japan as a country has faced some of the worst natural disasters including the Fukushima nuclear disaster resulting from a devastating Tsunami in 2011. Under the 1961 Disaster Counter Measures Basic Act, a central Disaster Management Council was formulated in the overall policy for DRM to work as a national coordination body on disaster management. Interestingly the council chaired by the prime minister drew experts coming from various specializations including those representing the public broadcasting and banks, making it interdisciplinary and stakeholder-centric (https://www.preventionweb.net/files/29163_drmkn221.pdf).

There has been in general a perception among critics that during disasters including the Fukushima, the news media shared in large measures news based only on what the government sources shared, which could be seen as a case of "press release journalism." The real stories emerged when international media wrote about the severity of the disaster and its repercussions. Scholars since the disaster have undertaken empirical studies to look at the state of media coverage. For instance, Martin Falkner commented, "During the Fukushima disaster, the media served government objectives such as preservation of social order by playing down the size of the accident and severity of radiological releases, resulting in widely divergent coverage from serious overseas media" (Falkner, 2021).

Sri Lanka

The Sri Lanka Disaster Management Act No. 13 of 2005 prescribes a disaster management council headed by the President of the country as the chairman and the Prime minister as the Vice Chairman. The council also has the leader of the opposition, which makes it inclusive. Ministers from various ministries and also chief ministers of its provincial council are also members of the council (http://www.unlocked.lk/wp-content/uploads/2019/06/Disaster-Management-Act_E.pdf). Surprisingly however, the Ministry of Information and Mass Media as it is called does not find a place in the Disaster Management Council. There is no ascribed role or scope for the news media in the Disaster Act of Sri Lanka.

There is some criticism of the Sri Lankan media for not covering enough the news on mitigation, relief, and recovery when compared to what the various media houses might be doing in organizing succor, thus following their own agenda (Galagedarage, 2018). During the Covid-19, many journalists' associations and

groups issued a joint statement exhorting the electronic and print media companies to implement measures for the protection of media persons covering the pandemic (<https://ifex.org/sri-lanka-media-owners-urged-to-prioritize-safety-of-journalists-during-covid-19-coverage/>).

USA

In the USA, the disaster management is coordinated in unison by many agencies including the local police, fire, health to the Federal Management Agency (FEMA). The disaster management works around four key areas, viz., mitigation, preparedness/training, response, and recovery. The document details preparedness and role play by various agencies and institutions including the nongovernmental and civil society organizations. There is no mention about the role of government communication dissemination protocol or the role of the news media except for a mention of the Mobile Emergency Resource Support (MERS) which is required to provide mobile telecommunications, life support, logistics, operational support, and power generation required for the on-site management of disaster response activities.

It is in this context that the current publication, the International Handbook on Disaster Research acquires much significance because those who conceived the book realized the importance of communication and media as important players in the overall disaster management. The role of media cannot be underestimated either in the ordinary or extraordinary times, as media is the channel that provides information to ordinary citizens to make sense of the world around them. Media also informs, educates, and interacts with people. There are empirical studies that suggest that media, especially the social media, has been very effective in times of disasters by connecting communities in raising alarm, reaching out to the affected, and sharing user-generated content, often from the sites of disasters. The disaster management authorities in various countries have also made ample use of mass media, especially radio and now social media, via mobile phones to alert communities of impending disasters like cyclones and flooding, thus saving many lives, by timely relocation of communities from the disaster sites.

European Union

Europe is considered, a relatively safer place but not unaffected by various man-made disasters. Over-urbanization and urban settings are believed to amplify disaster risks such as floods, epidemics, and heatwaves. Environmental challenges and global warming also contribute to disasters of varying kinds. While it is the responsibility of individual countries to set their own disaster risk policies and laws, the European Union has put together policies and joint funds to address collective safety and resilience against any impending adverse events. Under the EU Civil Protection Mechanism, 27 EU countries and six other participating countries exchange information on disaster risks on a continuous basis (<https://ec.europa.eu/echo/what/>

[civil-protection/european-disaster-risk-management_en](#)). The Emergency Response Coordination Center (ERCC) of the EU monitors events throughout the world to ensure rapid deployment of emergency support system with national civil protection authorities.

Here too, one finds many documents and protocols on risk mitigation and disaster management, but nothing specifically on the role and scope of communication and media.

Media, in covering disasters, often focus on the lapses of the disaster authorities which in many cases on the one hand has brought corrective action on the part of the disaster managers, but unfortunately on the other hand has also invited backlash against the media from the very same authorities for allegedly sensationalizing agony and suffering. It becomes a catch-22 situation for the news media on deciding what would be in the public interest to share and what may not please the authorities. When media does its job objectively, at least some quarters look at it as an adversary, but when it pushes only the official perspective, media is criticized for being in cahoots with the authorities in keeping away the facts from the general public. A critical media in disaster situation often leads to reputation management by the authorities.

Just to cite the role of social media from the recent history when Nepal experienced its worst earthquake in more than 80 years in April 2015 killing more than 9000 people (<https://www.worldvision.org/disaster-relief-news-stories/2015-nepal-earthquake-facts>), Facebook (FB) activated its special feature *Safety Check* which helped friends and families to locate their near and dear ones. This feature meant that people closer to the site of the disaster could mark themselves safe and share with friends. Safety Check's feature also encouraged other users to share about people they knew were safe. FB came out with this feature after its engineers during the devastating Tohoku Earthquake and Tsunami in Japan had developed the Disaster Message Board in 2011 (<https://www.downtoearth.org.in/blog/how-people-turn-to-social-media-during-natural-disasters-49587>). It has been seen that people use the internet more frequently during a disaster to know not only about the location and magnitude of the disaster but also to get first-hand information from the site of the disaster. They often use social media platforms to check on their family and friends, and seek and provide support. During the flooding of many towns in Maharashtra including Mumbai in 2005 and years later in Kashmir, including Srinagar in 2014, many mainstream news channels in India ran a continuous scroll sharing messages of people to each other, especially the families and friends about their well-being.

Now on the content in this section...

The section on media and communication has been carefully curated with the rationale that Media, especially the news media, plays a very important role all through the various stages of disaster management. Media on its part sources news by various means, including being at the site of the disaster, government sources, nongovernment sources, communities, tip-offs, unauthorized sources, social media, and grapevine, among others. Each source has its own merits and pros and cons, impacting the perceptions of those affected by the disaster and people at large. Trust levels between the media and the authorities in charge of disaster management often

are at the lowest ebb in disaster times, each one suspecting the other of its intent in publishing certain news or keeping away vital information from the public.

The government often maintains a robust information dissemination network that is used both in normal and disaster times, which by its nature is not expected to be critical but only provides the government's perspective, which is also important to share.

The Corporate Inc. on its part has a well-entrenched and oiled communication apparatus that goes on in an overdrive in case of industrial disasters and also natural disasters when it decides to extend a helping hand under its Corporate Social Responsibility (CSR) drive. To cite an instance, during the second wave of Covid-19 in April–May 2021, when there was an acute shortage of oxygen in India, the large industrial houses came forward in converting their industrial oxygen to medical oxygen to fulfill the demand. The CEOs of vaccine manufacturing companies were interviewed to share when the vaccines would be available and about their manufacturing capacity and capability, but taking viewers on a virtual tour of their plants.

Entertainment media, especially the celebrities with a larger than life persona and a huge fan following usually come forward during disasters by reaching out to communities in distress and sourcing funds through events. India has had a long tradition of this phenomenon with some great results. During the Russia-Ukraine war in 2022, a number of Hollywood stars including Angelina Jolie visited the war-torn Ukraine to register her solidarity with ordinary people. Closer home, we found many Bollywood celebrities assisting hapless victims especially the migrant laborers with food and arranging for their transport back home during the Covid-19 emergency. Film star Sonu Sood became the face of Bollywood and emerged as an iconic figure during the pandemic.

The section on media and communication, keeping in view that disaster management is a multi-disciplinary and trans-disciplinary field, has looked at the entire media ecosystem to cover various aspects of information dissemination, both from the demand and supply sides, including various media platforms, government information dissemination apparatus, brand communication, media coverage, etc. It has also discussed the need for capacity building in training and hands-on skills to various stakeholders on disaster communication management.

In all there are 22 chapters in the Media and Communication section. The chapters have been contributed by academics, researchers, and professionals coming from the media sector. ► [Chapter 81, "Covid-19 Communication Strategies in India: An Analysis Using Social Amplification Risk Framework \(SARF\),"](#) by Md Shahid Akhter and Biswanath Dash draws from the "Social Amplification of Risk framework," examining the relationship between information sources with the nature of medium and social stations. The chapter highlights that risk concerning the Covid-19 pandemic was amplified or attenuated depending on social and political considerations. It calls for increased attention to the government's role in regulating and reframing communication strategies. ► [Chapter 84, "Post-Disaster Suffering: Amphan Cyclone in East Coast on India,"](#) by Subrat Kumar Mishra and Akanksha Shukla has taken up the case study of the super cyclonic storm Amphan which made

landfall in West Bengal on 20 May 2020, causing widespread damage in two states, West Bengal and Odisha, claiming 128 human lives. The chapter assesses the impact of these fatalities on the surviving members of the families based on qualitative research and reports of grief-focused journalism after the event. The study reveals that when a member of a family dies of a natural hazard, it leaves the survivors in trauma and distress on multiple fronts, viz., economic, social, and psychological. The chapter recommends workable measures for the survivors to secure their livelihood, food, nutrition, shelter, and physical and emotional well-being.

► [Chapter 89, “Disaster Communication and Trust,”](#) contributed by Nguyen Thi Thuy Hang and Tran Truong Gia Bao, deliberates on the monitoring of disasters and initiating counter-measures, positing how the media could gain the trust of the public when reporting on disasters is in full steam. The authors argue that even nations with a wealth of experience in dealing with such events, such as the USA and Japan, have faced criticism from the public in the past for their disaster communication strategies. The chapter discusses disaster communication in Vietnam by analyzing a specific case of communication during the 2020 floods in central Vietnam, identifying the causes of the communication problems, and proposing solutions to the challenge of securing public trust. ► [Chapter 83, “Interrogating the Role of Environmental Journalists in the Disaster Context,”](#) authors, Dinushika M. Yapa Abeywardhana, P.K.G.I. Lavangi Ranasinghe, and Luxshe Hariharan, argue that journalists can effectively monitor rehabilitation and restoration of essential supportive mechanisms post a disaster, despite the politicization of disasters. Under this backdrop, the ecological journalist’s role has been interrogated in various social settings. The chapter inquires the status and role of environmental journalists in the disaster context, particularly in Sri Lankan disaster events. Himanshu Shekhar Mishra, an active mainstream television journalist, in his ► [Chap. 86, “An Ethical Code for Disaster Journalism,”](#) attempts to codify the primary role and responsibilities of journalists in a disaster zone, the logistical challenges they face while communicating risk, and the moral/ethical questions that they have to face while gathering and disseminating news. The chapter suggests a standard operating procedure (SOP) that journalists need to develop to combat threats to their physical safety and health and codify risks involved in potentially hazardous/dangerous disaster zones. It also outlines a new methodology to interview disaster victims in a disaster zone with empathy and a greater sense of understanding of their trauma, loss, and pain. At a broader level, the chapter attempts to develop an ethical code for Disaster-sensitive Reporting and argues for a humanitarian approach in Disaster Journalism.

► [Chapter 95, “Media and Disaster Reporting: An Analysis of Kashmir Floods 2014,”](#) by Sabeha Mufti and Irfan Hashim analyzes the “agenda setting role” of the media with a focus on the leading media narrative at regional, national, and international levels to understand the overall media portrayal of events during the Kashmir flooding disaster in 2014. The analysis has been drawn using content analysis keeping in view the social and political realities. The findings reveal important implications for the understanding of media and the political narrative in the backdrop of the long-standing Kashmir discourse and the role of media.

Seema Goyal's ► [Chap. 96, "Role and Impact of Visual Imagery During Crisis,"](#) debates on the impact of photographs and videos and the power they possess in creating impressions and perceptions in the minds of the masses which could neither be denied nor underestimated. Any tool with so much power to shape the mind, argues the author, has to be understood and handled with extreme caution. Lack of critical thinking and understanding of the impact of a single picture or film can prove to be catastrophic, especially during a crisis when emotions run high and logical thinking takes a back seat. Panic and heightened emotional reactions resulting from insensitive or irresponsible visual imagery freely circulated on the social media platform can sometimes lead to undesirable overreactions and create additional difficulties in managing the crisis at hand.

The government often is the disaster manager in most cases, ► [Chap. 97, "Government Information Dissemination Structures and Processes in Disasters,"](#) by Shalini Narayanan makes a case about the ineffective communication as a part of the disaster management strategy which led to avoidable hardship to the common man during the Covid-19 pandemic in India. The chapter presents a case study of the pandemic as a lesson in communication during a disaster. ► [Chapter 88, "Media and Communication in Disaster Risk Reduction,"](#) by Juhi Ramrakhiyani discusses that despite many scientific and technological breakthroughs, there seems no letup in the loss of human life and property in a disaster. The aggregate of human and financial losses, collectively with redevelopment costs, she argues, makes disasters both a humanitarian and economic tragedy. Media provides a large potential and probability for enhancing disaster resilience and a chance to manage and increase the capacity building for early warning and education. As a result, with righteous use of media and communications, the author argues, the emergency organizations can strive to prepare a resilient community with increased capacity-building resources.

► [Chapter 93, "Social Media and Communication for Older Adults During Disasters: A Narrative Study of Aging Population in Kolkata, West Bengal,"](#) by Debarati Dhar aims to map the fears and apprehensions of older adults during disasters by examining their experiences. She argues that it is essential to study the various aspects (both physiological and psychological) of a crisis in the context of older adults and look at the possible ways of coping with the help of social media engagement. The central argument of this chapter is that social media can be utilized as a communication resource by older adults during a crisis. Prachee Majumder, Disha Dwivedi, and Garima Khera's ► [Chap. 90, "Social Media as a Catalyst in Disaster Risk Governance,"](#) makes a case for the role of social media that has grown exponentially, invading geographical limitations, administrative boundaries, and even the apparent limitations of technology for aid in disaster management in the face of information overload, which has come to be known as "infodemic." Carrying on with the same theme of social media, Jyotirmayee Tudu and Sourav Prakash Shit in their chapter, ► [Chap. 92, "Disaster Management and Communication Technology: The Prospect of Social Media"](#) focus on how the Indian government has used the tool of social media in spreading information to connect with the affected population. How far it has been able to establish a sustained two-way communication within the governmental agencies and with citizens and whether the use of social media in managing disasters has opened up a new chapter toward digital democracy in disaster management practices is a moot point.

Radio for long has been used effectively in reaching out to communities in far-off places in many developing countries, Mohammad Sahid Ullah's ► Chap. 82, "Keep Me Safe from Cyclones: Community Radio and Disaster Campaign in the Coastal Areas of Bangladesh," examines the broader influence of the programs broadcast from the four community radio stations in the country in the context of evacuation and preparedness measures during cyclones. The study recommends the developing of localized broadcast plans for cyclone warning campaigns, a step that would significantly contribute to the safety of the community at large.

Yet another chapter on the same medium, ► Chap. 99, "Radio for Disaster Management," Rajeev Kumar Shukla argues that although all media platforms are active partners in disaster management communication, radio proves to be the most immediate, intimate, and accessible medium due to its faster and larger reach, affordability, and simpler technology, making it indispensable in a disaster situation. When a disaster strikes, it affects a wide range of communities, interests, and professions, Ipsita Barat's ► Chap. 94, "Pandemic Survival Strategy of Hindi Film Studios: The Case Study on Yash Raj Films," attempts to gauge how the industry players, especially the famous Yash Raj Films (YRF), survived and sustained itself during the pandemic. A collective understanding has been that the industry survived by creating alliance with Over-The-Top (OTT) streaming platforms such as Netflix, Prime, and Hotstar. However, YRF had no OTT film released in 2020. YRF, despite no such alliance, was able to survive the pandemic times and continued to do so by adopting an effective business strategy.

Medium- and small-sized industries suffered the most during the pandemic globally. In ► Chap. 67, "Resilience of MSMEs During the Pandemic," Deepmala Baghel has looked at the repercussions of the Covid-19 on MSMEs and whether they were able manage the crisis in the Nagpur District of the State of Maharashtra. The results of her study indicate that MSMEs faced myriad problems following Covid-19 mainly because of their inherent characteristics of being small-scale operations, limited monetary base, and a confined area of operation. The author has suggested an appropriate policy framework, emphasizing on the need for both monetary and empathetic governance to support MSMEs' organizational resiliency.

► Chapter 98, "Reinventing Fashion Industry to Sustain Itself During Covid-19," by Meha Jayaswal gives an interesting perspective on how the Covid-19 pandemic affected the fashion industry globally and how some major fashion brands and individual fashion designers stood to the challenges when the market was absolutely down and out. The chapter discusses how some of them contributed to bringing succor to communities and reinventing their brand perspectives in a crisis.

On the same theme, in ► Chap. 91, "Pandemic and Brand Communication in India," Tanu Dang argues in the Indian context on how during the pandemic, brand attitude and brand reputation gained greater relevance over brand positioning. Consumers not only evaluated the ways in which brands dealt with the pandemic but also shifted loyalty, if their favorite brands failed to act responsibly during the crisis. Brand communications evolved new ways to humanize their brand in order to make it more relatable to their consumers. ► Chapter 85, "Outreach Strategies Adopted by Corporate Organizations for Flood-Affected Communities in India," by Kulveen Trehan, discusses the role of corporate organizations in carrying out

community outreach during floods in India, by employing various strategies and tactics of branding and social responsibility in their involvement in the flood management cycle. Their outreach efforts, the author argues, got recognized during the Kerala floods (2018), thus consolidating their role in the disaster ecosystem. Interviews with different persons involved in flood management, disaster research, mitigation, media, and corporate communication brought in focus the higher outreach marketing by companies using their products and use of social media during floods.

► Chapter 87, “Capacity Building Through Stakeholder Training in Media and Communication for Effective Disaster Management,” by Jaishri Jethwaney explores the multi-pronged challenges in disaster management but most importantly how the people in charge of disaster management and communication need to be trained to do a professional job in the face of a disaster. Among the various stakeholders who need to be sensitized and trained, the most crucial include the civil servants, who are called upon to administer/manage disasters, the information public relations personnel in the central and state governments who disseminate information to the media on behalf of the government, disaster management teams at ground zero and at head office level, the communities at the grassroots level, and last but not the least the media persons who need to be exposed and sensitized to the disaster management emergency response system and the preparedness of the administration in dealing with any kind of situation so that their reportage is balanced. The chapter provides an outline of the training content, pedagogy, and hands-on skills on disaster communication for various stakeholders.

In summation, the part on “Media and Communication” in the current International Handbook on Disaster Research hopefully will amplify the debate on the role of media and communication in disaster management among academics, policy makers, and lawmakers among others. The section expectantly would also be contextualized with other segments of the handbook to reinforce the argument that a trans-disciplinary approach to disaster management is not a choice, but a necessity.

Abstract

The Pandemic showed the world at large that appropriate risk communication strategies are of vital importance to deal with a disaster of unprecedented scale. Conventional communication alongside a host of social media played a range of roles from spreading awareness, building preparedness, reducing mental anxiety and associated stigma, spurring policies and action to spreading misinformation, reinforcing popular myths, blurring the distinction between science and pseudo-science. This chapter seeks to understand how effective the communication strategies were in India during the Covid Pandemic. Drawing from the “Social Amplification of Risk framework” it examines the relationship between information sources with the nature of medium and social stations. The broad objective is to understand how social and cultural factors shape the impact of communication. The study highlights that risk concerning the pandemic was amplified or attenuated depending on social and political considerations. It calls for increased

Introduction

The frequency of disease outbreaks and disasters has risen over the last few decades (CRED & UNDRR, 2021). Modern society characterized with all kinds of risks indicates a sense of insecurity for the present while raising the concerns for the future (Rayner, 1987). Unprecedented scale of urbanization, deforestation, and simultaneous change in climate and consequent impacts have resulted in bringing animals and humans' sphere of existence much closer than ever before. Such close proximity intensifies chances of infectious diseases outbreak and an upsurge in occurrences of epidemics and pandemics (Harvard, 2020). The spread of SARS (2003), HINI (2009), MERS (2012), and COVID-19 are clear reminders that biological disasters are not as infrequent or region-specific as it was perceived to be at one point of time. SARS-CoV-2 (henceforth COVID-19) originated from Wuhan China and created one of the biggest global health crises within a short span of 6 months (Lee et al., 2021). The contagious nature of this disease was the major cause of public concern and it continues to create panic well into the third year of its initial outbreak. In such a situation, societies require an appropriate public health communication strategy to protect themselves from the adverse impacts of ongoing Pandemic and future disasters.

An effective risk communication strategy is vital for public ingestion of pandemic information and to convince people to behave in an appropriate manner (Bernhardt, 2004). A long and protracted spell meant that risk perceptions of people varied and tended to be low during crucial phases. The growing fatigue and high stress due to uncertainty and limited trust and confidence in governmental response contributed to a near breakdown of the fabric with which our communities are made of (Mackenzie et al., 2014). Thus, the strategies to manage these risks effectively require better communication between different individuals, groups, stewards, government agencies, and members of society (Hanafiah, 2018; Matta, 2020). A robust risk communication strategy therefore must exist at all levels from global, national, and regional to local and is a prerequisite to contain the transmission and handle the disaster effectively.

Risk communication strategies are often treated as supplementary efforts in dealing with outbreaks rather than being treated as an integral part of the successful responses to any public health emergencies (WHO, 2017). To make communication effective and to promote people-centric response, community's engagement, empowerment, coordination, and localization are imperative. Without community involvement, there is a danger of confusion and escalation of misinformation and

mistrust undermining the efforts of lifesaving tools, information, and services. What and how the communication process should be is a question which has engaged researchers across the world and several models and frameworks are proposed to capture the process through which risk messages progress from its origin to the final receiver. This chapter focuses on various communication models in general and social amplification of risk framework (SARF) in particular to examine COVID-19 risk communication practices and its entanglement with social, institutional, and cultural practices.

Risk Communication

In the classical notion of risk communication, the major sources of risk information are scientists, public agencies, or interest groups such as environmentalists or industries, eye witnesses in the case of hazardous events, etc. Such primary sources send information in the form of personal interviews, press releases, and reports to transmitters or occasionally send them directly to the final receivers. The coding or re-recording of risk information at the transmitting stations is the next step of communication. The media, public institutions, opinion leaders, and interest groups are potential transmitters of risk information. As transmitters, the mass media dominates, but interest groups often act as information brokers. The information receivers can be subcategorized into general public, affected citizens, socially exposed individuals, and members of different types of social groups. The last step of communication is the processing of the re-coded messages at the final receiver. Again, receivers can be categorized into different groups. The mass media usually serve the general public, while many mediums target specific groups or audiences. Specialized journals are again appealing to diverse groups such as science communities, risk assessors, environmentalists, religious groups, political camps, etc. In addition, citizens directly affected by the event may process the information differently from the other non-affected persons. The effects of the risk information depend upon the targeted audience and its amplification mechanisms in receiving and processing the information.

Risk Communication Approaches

A number of risk communication models have been proposed and through their use, attempts are made to outline efficient and effective practices. Broadly, risk communication is a complex activity involving different types of communicators such as media, government agencies, scientists, etc. Smillie and Blissett (2010) postulate a three-phase model, consisting of risk appraisal, source analysis, and situational analysis. In this approach, risk appraisal involves an objective overview of scientific facts. The second phase or situational analysis focuses on perceived risk through the lens of the outside world and the third or source analysis refers to responsible communicator's self-analysis.

A highly discussed risk communication model, known as Internalization, Distribution, Explanation and Action or shortly IDEA was developed by Sellnow et al. (2017). It has four key components: a) Internalization motivating receivers to attend and remember the message b) Distribution or the essential elements that disparate audiences receive during a crisis. c) Explanation to understand the accuracy of risk information, and d) Action, or the process through which appropriate actions can be taken. Veil et al. (2008) outlines strategies, which may be useful to establish a reliable risk communication model within organizations. It views preparedness and prior proactive measures before occurrence of an event to be of vital significance. According to Sellnow et al. (2009), to achieve the best practices in risk communication, nine core principles require to be valued. They are: treat risk communication as a process; infuse it into policy and decisions taking; focus on uncertainty aspects of risk; design risk messages based on the sensitivity of the culture; acknowledge diverse levels of risk tolerance; present messages with honesty; should be accessible to the public; collaboration with credible sources; and involve the public in dialogue about risk.

A message-centric approach, for example, as proposed by Zhang et al. (2020) (Fig. 1) argues that limited information and delayed decision-making at local government level are important in making the communication ineffective. This approach entails that government, experts and the public constitute the three core pillars of public health-related risk communication. In the interaction among these three components such as government-expert, government-public, and expert-public, key risk governance decision-making process remains with the government

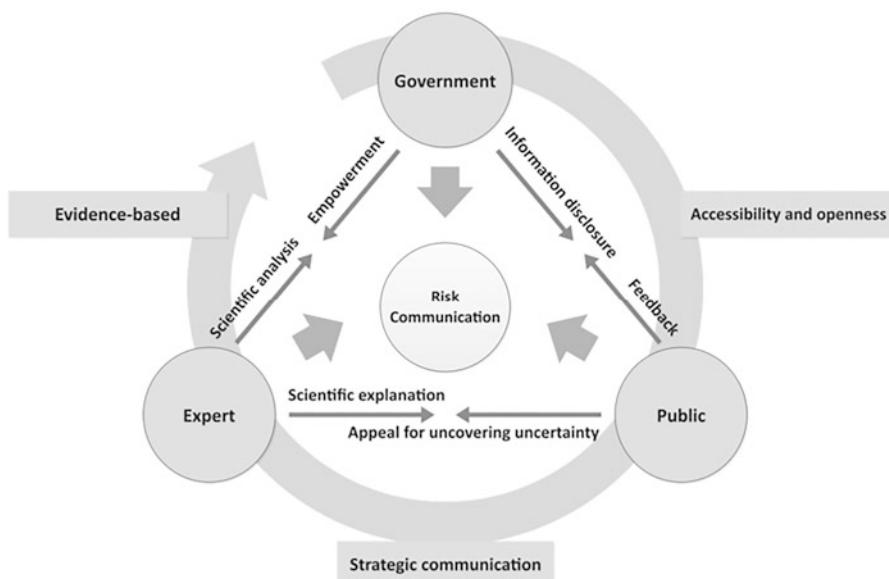

Fig. 1 Government-Expert-Public Communication model. (Source: (Zhang et al., 2020))

for example, in government-expert communication for internal risk assessment and government-public communication, to convey adequate and accurate risk information to the public, government carries key roles and responsibilities.

The Crisis Emergency Risk Communication (CERC) model developed by the Center for Disease and Control (CDC), USA is regarded as one of the most effective public health emergency communication models (Herovic et al., 2020). The CERC model views communication evolving through five phases: pre-crisis, initial, maintenance, resolution, and evaluation. It points to an evolution throughout a life cycle, be it crisis, emergency, or disaster; they evolve in phases and so also is the risk communication. The experience during the Pandemic in different country's context show the merit of such an approach particularly in a protracted disaster that itself evolved over time.

Risk Communication Framework

In the wake of the declaration of a pandemic on 11 March 2020, the World Health Organization (WHO) advised countries to follow a whole-of-society and a whole-of-government approach. Information Network for Epidemics (EPI-WIN) was introduced to fight against “infodemic” (WHO, 2020a). The use of scientific terms was often difficult for the public and it was suggested that pandemic risk messages be crafted in simple, clear, short, and to the point format for audiences (CDC, 2018). Further, the Global Outbreak Alert and Response Network (Mackenzie et al., 2014) was developed with the collaboration of 250 technical institutions across the world to establish an integrated global and national risk communication platform and to imply risk messages in a local context. Visuals and infographics messages were important for social media to promote protective measures such as hand washing, social distancing, cleaning and disinfecting objects and surfaces. WHO released a set of infographics, known as “COVID-19 – Know the Facts” and undertook other measures, for example, it teamed up with Google and social media companies for pandemic-related queries to be redirected to the WHO web page (Zarocostas, 2020). Training courses were also conducted in collaboration with celebrities to reach a diverse audience (WHO, 2020a). In the face of such initiatives, there was clear variation however over the extent of adherence to the suggested protective measures in the given context. For example, Varghese et al. (2021) (Table 1) found that European Countries differed in their adherence to a set of six basic preventive measures recommended by the WHO.

Social Amplification Risk Framework (SARF)

Social Amplification Risk Framework (SARF) is a dynamic model that does not fit well with the traditional communication model of information transmission between sources, transmitters, and final receivers. The classical models were initially developed in the late 1940s (Chandler, 1994; Lasswell, 1948), and they remain popular in

Table 1 European Countries ranked for their level of adherence

Rank	WHO recommendations	Top Adherers	Worst Adherers
1	Avoid shaking hands, hugging or kissing while greeting others	Portugal, Italy	Denmark
2	Keep a distance of at least 1 meter	Portugal, Italy	France
3	Cover nose and mouth while coughing or sneezing	Portugal	France
4	Regularly wash hands with soap	Portugal	Denmark
5	Use alcohol-based hand rub	Portugal	Germany
6	Avoid touching nose, eyes, and mouth	Portugal, Italy	Denmark

Source: (Varghese et al., 2021)

communication studies. SARF on the other hand identifies numerous intermediators that intervene between the risk event and its consequences, and recommends a causal and temporal sequence for compelling actions. From the origin to the end receiver, information flows through various channels – initiating individual stations, triggering social stations of amplification, and precipitating behavioral reactions. They produce ripple effects, which further lead to secondary impacts.

However, any model with simple logical structure may be inappropriate to analyze or capture the complexity of social communication (Rayner, 1988; Rip, 1988). For example, Lasswell's (1948) idea of "who says what to whom, how and with what effect" was the guiding tools on communication research over three decades. According to this model, the mass media is the core transmitter of information in society. With the coding process of a message, the flow of information starts at the source station, from which it goes to transmitters, where it is decoded then re-coded and transmitted further to the next transmitter or the final receiver. The original message gets altered either intensified or attenuated by each transmitter, and incoming signals can get added or omitted. The new cluster of signals is received by the next transmitter or the final receiver, which decodes, evaluates, and deciphers the information contained therein.

Signal Amplifiers: In social communication, signals without meaning are regarded as noise, and a cluster of meaningful signals on the same topic is considered a message. Any change or alteration of signals may change the meaning of the message. The change of messages during transmission is the main concept of the social amplification model.

Message Components: The amplification mechanisms of signals are based on two criteria: quantity and placement. Both are powerful agents with style and composition being additional mechanisms frequently used in coding or re-coding of messages. The coded messages can be in written or oral form. By using the mechanisms of signal amplification, different components of the message can be amplified by transmitters. Adding or deleting symbols is probably the most important mechanism in order to amplify or attenuate the original message (Renn, 1991).

Source of Messages: The framing of a message at its source is the first stage of communication. There are three levels of information source: individuals, social groups, and political institutions. At an individual level, messages are composed based on personal experiences, and it is rather rare in risk communication, unless they are directly affected by a cause of risk or eyewitnesses of a risk event. The amplification of these messages will only occur when mass media reports about this topic and agencies or fellow citizens highlight the topic as part of its own agenda (Peters, 1986). Therefore, the response of public agency, media interest, and individual action are all essential tools to fuel the amplification process.

Information Receiver: Receiver can be classified into micro, meso, and macro types, which can also be termed as individuals, groups, or institutions. Amplification during reception may differ between individuals, members of social groups, and public institutions. The cognitive processes along with emotional and subconscious processes play vital roles in filtering the incoming messages and co-determining evaluation (Renn et al., 1992). In the procedure of signal transfer, there are a number of stages through which individuals receive the signals, articulate them, and transform them gradually into an enduring belief (Renn, 1991).

SARF framework comprises mainly two stages. The first stage focuses on an event and its relation to public perceptions and their first order behavioral responses that are influenced by various amplifying/attenuating platforms. These stations of amplification can be social and individual, and the creation and process of signals rely upon qualities of these stations. In the second stage, emphasis shifts to secondary impacts and a direct link is established between the amplification of risk perception, behavioral reactions, and secondary consequences. These consequences include direct and indirect impacts such as loss of confidence in institutions, insurance, and liability cost, or alienation from community affairs (Kasperson et al., 1988, p. 181) (Fig. 2).

The consequences of an event are perceived at individual, social, and cultural levels. The response of individuals to a specific event depends on their perception, value, convictions, and surrounding social and cultural risk environment. The processes not only provide experience of a physical threat, but also disclose a new meaning or create subjective interpretations of risk (Pidgeon et al., 2003). Kasperson et al. (1988) explain how hazards that have relatively lower risk, for example, nuclear energy receive strong response (Amplification), while hazards such as smoking, air pollution, etc., which are no less dangerous are often ignored. They argue that how individuals understand and evaluate risk, and respond to it is shaped by a range of factors, namely, social, cultural, and institutional platforms. Thus, SARF suggests that social, cultural, psychological, and institutional processes may broaden or constrain the temporal and spatial scales of impacts (Renn et al., 1992).

In addition to the two stages, SARF can be further formulated through two other steps: information mechanism and response mechanism. There are four information mechanisms that intensify risk perception at the initial stage of transmitting risk messages. They are volume of information; degree of dispute or ambiguity of information; the level of dramatization; and types in which information is symbolized (Pidgeon et al., 2003, p. 14; Kasperson, 1992). There are also four types of

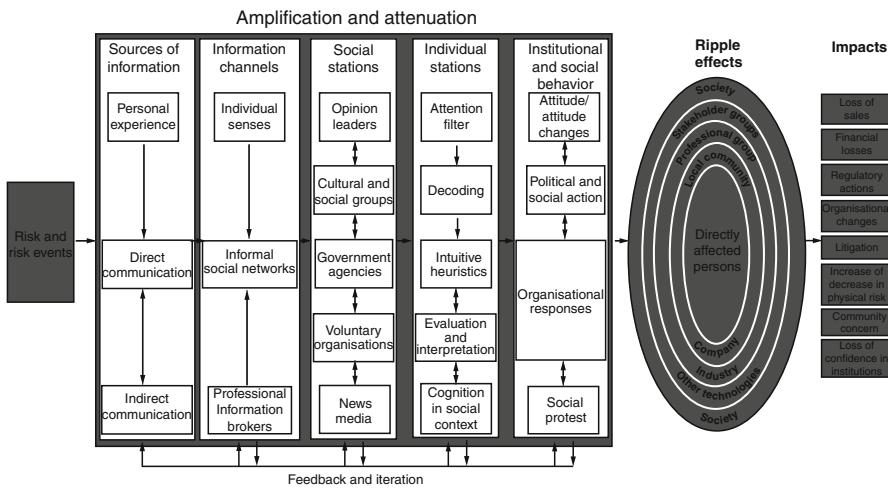

Fig. 2 Social Amplification Risk Framework (SARF). (Source: (Pidgeon et al., 2003, p. 14))

response mechanisms, which are: inquisitive form of knowing or valuing an event; the relationship among social group, political, and ideological commitments; high signal value event, for example, elevating seriousness of an existing one or introducing a new risk; the stigmatization that refers to the negative imagery of objects or undesirable individuals and groups connected to an event.

Covid-19: Communication Strategies in India

Institutional Mechanism

India's brief history of pandemics and epidemics include Cholera 1817–1899, Bombay plague 1896, Influenza 1918, Polio 1970–1990, Smallpox 1974, Surat plague 1994, Dengue 2003 and 2006, SARS 2003, Chikungunya 2006, H1N1 flu 2009, Indian Swine flu 2015, and Nipah 2018 (Chattu et al., 2018). In recent times, the Government of India has played a lead role in the management of Ebola and outbreak of H1N1 through experiences and realized that an effective COVID-19 communication strategy is essential for strengthening coordination and cooperation across all levels. The Ministry of Health and Family Welfare (henceforth MoHFW) is the nodal central agency for management of an incident amounting to a national public health emergency. Crisis Management Group (CMG) and National Risk Communication Committee (NRCC) are the institutional mechanisms at the national level mandated to ensure effective coordination and provide appropriate directions. CMG and NRCC receive technical advisories from the Director General Health Services Government of India, and similar mechanisms operate at the state and

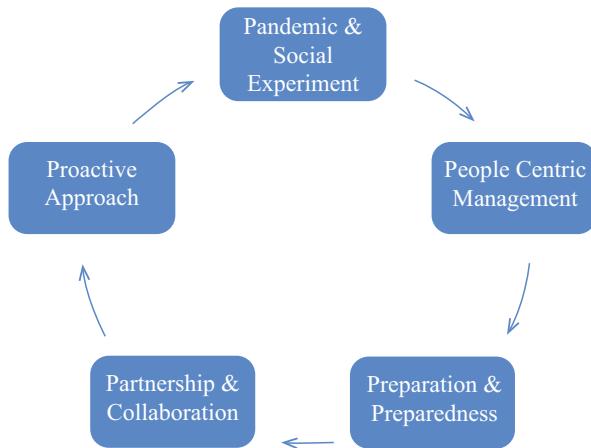

district levels in the form of State Risk Communication Committee, and District Risk Communication Committee, respectively.

The social experiment of achieving a physical distance for over 1.3 billion populations in India and over a substantive period of time provided much to learn from in terms of disaster risk communication and management. The nationwide lockdown, both voluntary and involuntary confinement and consequent challenges thereof, carry important learnings from the perspective of preparedness (French & Mykhalovskiy, 2013). The Integrated Disease Surveillance Project (IDSP), an important initiative of the Central Government underway since 2004 provided the much required infrastructure at the local level to detect risk at an early stage (Srivastava & Shainesh, 2015). This program was ably supported by other agencies such as Indian Space Research Organization (ISRO), National Informatics Centers (NIC) for district level surveillance, and the MoHFW, which in association with Indian Council of Medical Research (ICMR) provided three tier labs network and diagnostic centers, (Nomani & Sherwani, 2020), all of which are important source and widely regarded for their credibility.

Risk Communication Strategy

A general classification such as short-, medium- and long-term plans and actions can be useful to understand employed communication strategy in India over a long period. In this conception, a short-term process deals with relief-driven approaches and distribution of pandemic's information. The medium-term strategy focuses on socioeconomic recovery and welfare approach, and the long-term mostly addresses the diagnostic and prognostic remedies (Hao et al., 2020). From the initial stage itself, MoHFW began a practice of releasing a daily update on COVID-19 situation and the briefing was usually a well-publicized event and it was broadcast live by most of the television channels. Similar briefing was subsequently conducted on a daily basis by a number of Indian states. A wide range of Information, Education, and Communication (IEC) initiatives was prepared for different types of audiences such as quarantined, vulnerable groups, frontline workers including health professionals, and the general population. Public Service Broadcasters in collaboration with MoHFW telecasted a total of 36 COVID-19 affiliated videos on national television channels including the government-owned Doordarshan and they were also hosted on MoHFW website. The videos were made combining text, audio, animation, and voice-over and generally contained information on essential protective behaviors (Purohit & Mehta, 2020). A central repository of Standard Operating Procedures (SOP) and relevant Guidelines were created for quick retrieval to provide easy access to authentic information. A very effective means of communication, for example, was the consolidation of overall management approaches within five Ps: Pandemic and Social Experiment, People-Centric Management, Preparations and Preparedness, Partnership and Collaboration, and Proactive Approach (Fig. 3). The value of such an effort lies in its attempt for innovative representation of important management attributes.

Fig. 3 Five Ps of disaster management. (Source: (Nomani & Parveen, 2021))

The Center of Disease and Control (CDC) created an active web page on Twitter and Facebook to post and circulate large numbers of short messages within a short span of time. All India Institute of Medical Sciences (AIMS) the premier medical research institute in India conducted periodical webinars to communicate appropriate measures and procedures relating to treatment and institutional preparedness. For example, telemedicine guidelines were formulated and provided for wider healthcare access. An interactive epidemiological dashboard was created in several cities displaying the total number of corona cases, deaths, availability of hospital beds, and other critical information. “Break the Chain” a particular campaign by the Government of Kerala was found to be effective in communicating the importance of appropriate behavior (Line, 2020). Caller tunes, for example, were set in regional languages in order to make local people understand about the guidelines and protocols related to infection and stigma (Times of India, 2021).

A specific component of the MoHFW'S communication strategy was to include social influencers such as religious leaders and public celebrities to join the risk communication campaign. Political representatives were included on a regular basis for risk communication during the pandemic. Members of Indian Parliament or MPs, Members of State Legislative Assembly or MLAs, and that of Village Gram Sabhas and Gram Panchayats (GP) were part of the government communication plan to reach out to the wider public. This strategy was replicated during COVID-19 Vaccine drive as well during which it was further expanded to involve health practitioners of all streams, Auxiliary Nurse Midwives (ANMS), Faith leaders, Self-Help-Groups (SHG), etc.

Mass Media: Print, Television, and Radio

The mass media – print, television, radio, and internet – not only has a vast outreach but also plays a very prominent role during public health emergencies (Sharma et al., 2020). For example, during the Pandemic, frontline workers and government

agencies relied greatly on mass media to remain updated on latest government directions and information. Since pre-independence times, print media has emerged as an important means for communication in India, for example, it played a remarkable role during the country's freedom struggle (Dhanashree et al., 2020). Over the years, print media has earned credibility for its unbiased, accurate, factual, and objective reporting. It continues to carry forward the same reputation; recently it was evaluated to be the most trusted among readers as compared to web based or electronic media outlets (Saxena, 2021). As per a report of Ministry of Information Broadcasting, India has over 143,423 registered newspapers and periodicals during 2020–2021. The newsprint industry however was one of the worst affected in the pandemic and suffered severe financial crisis. During the early lockdown period, estimated losses of print media for 2 months – March and April 2020 – was as high as INR 4, 500 crores (The Times of India, 2020). According to the World Association of Newspapers and News Publishers, (as cited in Saxena, 2021), Indian publishing houses generally are facing a revenue crisis of an enormous scale and have entered into a debt trap. Porwal (2020) further points out that high production cost and new customs duty have only created additional pressure on them for sustenance.

In contrast, a positive upsurge was observed during the lockdown as far as viewership of television is concerned (Dhanashree et al., 2020). India has more than 900 private satellite television channels (MIB, 2020). In the early period of the Pandemic, keeping in mind the unusual nature of the enforced preventive measure, the central government decided to re-telecast various popular television serials. The government-owned television channel Doordarshan thus received a very positive acknowledgment for doing so. Further it initiated telecasting educational programs with an aim to augment the learning process and reach out to students particularly those in highly remote locations. A number of health awareness programs were played out on a routine basis as well to promote mental health, and reduce fear and stigma among people (Romero-Blanco et al., 2020).

Notwithstanding proliferation of satellite television, radio as a mass medium continues to perform an important role, for example, in dealing with fake news through authentic sources. In a country where internet is yet to reach majority, radio remains the most important for those left out of the digital divide (Pavarala & Jena, 2020). The Prime Minister of India thus announced the nationwide lockdown through a popular radio show “Mann Ki Baat” highlighting the importance accorded to the medium. As per a study of the Association of Radio Operators for India (AROI), radio listenership during the lockdown surged by 23% to record 51 million listenership, which is close to television (56 million) and social media (57 million) (Moneycontrol, 2020). A number of radio programs such as “Zindagi Kaise Jiye” (How to live life?), Savdhan (Be Alert), “Corona se Jung” (War against Corona), etc., were broadcasted in different languages providing information on public hygiene and sensitizing over various lockdown regulations (Pavarala & Jena, 2020). Globally, there are approximately 5000 community radio stations, and around 500 stations are in South Asian countries (Pavarala & Malik, 2007). During COVID-19, community radio ensured democratization of information for the

diversified rural populace in developing countries (Laskar & Bhattacharyya, 2021). India has 310 community radio stations, half of which are operated by Non-Government Organizations (NGO) and roughly 7% are operated by Krishi Vigyan Kendras (MIB, 2020). The mass media however is not entirely free from inaccuracy, errors, infringement, and aggrandizement (Snow, 2008; Leask et al., 2010). For example, they are required to be more accountable for their role in creating panic during the public health crisis and contributing to psychological stress and anxieties.

Social Media

Social media has brought about a significant change in communication dynamics. The web platforms and mobile-based technologies that enable users to create content collaborate and exchange among the participants and members have altered both communication patterns and development of appropriate strategies (Cohen, 2011). COVID-19-related news, opinions, and stories spread with a single touch of a screen, moving from individuals to millions across the globe within a short span of time. In the early period of the pandemic when there was no medicine or cure available, social media was widely used to spread public health awareness (Farnan et al., 2013). The easy mode of use and low-cost tools helped Government and Public Health Officials to diffuse relevant information and news to a large number of people (Merchant et al., 2011). Most of the Public Health agencies carried active social media sites, which were used to spread and communicate both among agencies and with the public (Thackeray et al., 2012). Although the role of social media in COVID-19 outbreaks is receiving attention, little is known about the mechanisms of social media use and its effects on risk perception and preventive behavior toward outbreaks.

During the Pandemic, risk information was carried over numerous websites hosted by diverse kinds of entities and in different Indian languages. The country has more than 560 million internet users, which is second highest in the world after China. There are more than two billion social media users, and on a daily basis, more than 500 billion tweets are posted from twitter (Farsi, 2021). During Covid lockdown, social media was the most preferred medium to exchange information with WhatsApp, Facebook, and YouTube being some of the most popular platforms (Internet Usage in India 2020). Based on analysis of social media messages, it is found that during the first lockdown most Indians were positive and there were fewer instances of anger, disgust, and sadness (Chehal et al. 2021; Barkur & Vibha, 2020). In the second phase of lockdown, the most trending topics were AarogyaSeva app, wear mask challenge, respect for coronavirus warriors. In the third phase of lockdown, the set of trending topics changed to issues such as Liquor Shops, Self-Reliant India, etc.

Public health professionals and healthcare organizations have long realized the value of social media in communicating health-related information (Bender et al., 2013). During COVID-19, political leaders in particular were found to have extensively used social media platforms like Twitter to disseminate or communicate with the public. A study, for example, shows that almost 90% leaders in India shared fact-

based positive or neutral information rather than statements in the form of opinions. The types of information that were shared by political leaders fall into the category of guidelines, daily updates, awareness campaigns, actions, appeals, appreciation and moral boosting, financial and non-financial assistance (Kaur et al., 2021).

Use of Social Media for Risk Communication: Challenges

During COVID-19, spreading of false information or “infodemic” posed the most serious threat to public health and management effectiveness. The scale of this challenge can be seen from a statement from Secretary General of the World Health Organization (WHO), Antonio Guterres who posted on Twitter saying that “Our common enemy is #COVID-19, but our enemy is also ‘infodemic’” (United Nations, 2020, May 28). Misinformation propagated mainly through social media created panic and anxiety. Several implausible claims relating to the virus and the spread of unproven and unscientific facts in the media posed enormous challenges to authorities (Kim et al., 2019). Facebook and Twitter being the two most important social media platforms (Mitchell et al., 2016) were also found to be major sources of such misinformation (Garrett, 2019; Vicario et al., 2016). It thus points toward a growing concern among provincial decision-makers to negotiate the way information gets mobilized in multiple directions and from diverse sources.

Some of the specific fallout of these practices include: a) maligning professional image, for example, posting and forwarding information with unethical and fabricated contents have adverse effects on the psychological condition of healthcare students, doctors, and other medical professionals (Peck, 2014). Social media service plays a crucial role in shaping the belief, personality, and interest of the commons and creates impressions in the mind of people. b) Similarly an inaccuracy, which often is difficult to be detected from a large volume of abridged, informal, and partial nature of information, can potentially create environs of panic and disturbance. To add to it, the desire to spike popularity act as an incentive for many users to post morphed or distorted videos and images (Moorhead et al., 2013). c) The psychological consequences of misinformation can exhibit in various forms, for example, anxiety, stress, trauma, worries, etc. (Roy et al., 2020).

Trusting the Source

The acceptance of information particularly in crises depends on the credibility and trustworthiness of sources. It is generally seen that people tend to believe in information shared by health experts, doctors, and scientists (68%), followed by the World Health Organization (56%) (WHO, 2020b). However, as far as politicians as an information source is concerned, there appears to be much variation. A number of structural factors can be attributed for the low level of trust such as lack of transparency, incompetent leadership, or cultural and historical factors. It is equally important to have an appropriate information channel to communicate evidence-based information effectively. A report from Myanmar suggests that as a media channel, radio is considered one of the most trusted although only 20% of the local

population receive information through radio (WHO, 2020c). Similarly, in Colombia, 88% respondents of a survey reported that they received Covid-related information through television but only 32% indicated that they trusted the channels. Other studies corroborate similar findings, for example, health workers (50%), television (44%), and newspaper and radio (38%) are found to be rated higher on reliability parameters. Importantly, while exposure to the online sources is rapidly growing, level of trust for these sources is still generally low (WHO, 2020d).

Discussion and Conclusion

The million deaths due to Covid-19 across the world have pushed human societies into turmoil and have left us economically in very dire straits. However, there are several lessons that should not be lost with regard to risk communication and its primacy in negotiating future challenges. In this chapter, analysis of India's strategy points toward the importance of advance planning, quick announcement as and when there is an outbreak, and being honest about risk messages with the public, as well as with various stakeholders. Besides, building public trust on government plans and actions, and a formulation of a communication strategy characterized with compassion and empathy have positive reception. The occurrences of health emergencies in India in the form of Bird flu, Swine flu, Severe Acute Respiratory Syndrome (SARS), Middle East Respiratory Syndrome (MERS), Nipah and, Ebola in recent times were helpful for realizing the significance of risk communication and a better understanding of its unaddressed aspects. For example, it brought to fore the requirement of a strategy that focuses on communicating awareness and proactive actions in the initial stage, a responsive and reactive action in the subsequent phases, and focus on social and mental health recovery during the final stage.

The Social Amplification Risk Framework (SARF) (Pidgeon et al., 2003) has much scope for applications and in this case, it carries relevance to understand how Covid-19 risk has been perceived and transmitted, amplified and attenuated through social filters. A review of recent studies point toward the role of social media platforms through which social, technical, and scientific risk mitigation and preparedness ideas merged through visuals and infographics and promoted protective measures. In the Indian context, several organizations such as National Disaster Management Authority (NDMA), National Informatics Centers (NIC), Indian Council of Medical Research, Indian Space Research Organization, and Programs such as Integrated Disease Surveillance, etc., collaborated for an effective risk communication strategy. Such strategies were fine-tuned with support from different levels of government, for example, National, State, and District level Risk Communication Committees.

This study draws three key lessons: the first, proliferation and popularity of social media, which warrant a rethink on conventional risk communication approaches. The COVID-19 risk communication in India reinforced two distinct features: social media on one hand helped communicate the risk with much effectiveness and on the other hand they carried a significant role in spreading erroneous and inaccurate

information, creating a distorted risk perception of an existing objective threat. Recognition of these two sides is prerequisite for formulation of better communication strategies. The second lesson is that the credibility of sources of information, which for COVID-19 were mostly government agencies, helped in achieving a positive outcome for the process of communication. Such credibility is gained through years of good performance and it is thus of utmost importance that the source agencies retain or improve their own performance for future benefits. Finally to improve and develop effective risk communication requires recognition of the role of varied social actors and cultural context in which risk messages evolve. A deeper examination of the nature of interaction is necessary to explain success and failure of risk communication strategy in different Indian contexts.

Abstract

This study examines the broader influence of four community radio stations' programs in the context of evacuation and preparedness measures with a month-long observation of people's behavior during cyclones. This study also engages 16 in-depth interviews with radio station managers, listeners' club members, and non-listeners across the coast. Study findings reveal that vulnerable people in isolated coastal areas and offshore islands continue to trust community radio for information related to cyclone preparedness and evacuation. Results of this study ascertain that listening to hazard-related programs on state-run and community radio stations has played a significant role in cyclone-related disaster prepared-

ness activities relating to minimizing cyclone-induced life and property losses. The distinct feature of broadcasting early warnings in local dialects has increased the comprehensibility, information clarity, and reliability of the warning messages delivered by community radio. Better access to information has helped at-risk people make adequate preparations as they face impending cyclone risks. These activities together appear to have helped community radio listeners to incur a significantly lower degree of losses than that of non-listeners. However, while safety campaigns deployed by community radio stations have the potential to increase preparedness and timely evacuation, it has also been found that the capacity of stations to serve as effective channels for disaster campaigns still has limitations, largely due to inadequate training in crisis communication. This study recommends developing localized broadcast plans for cyclone warning campaigns, a step that would significantly contribute to community safety.

Introduction

Cyclones with tidal surges are the most severe natural disasters in Bangladesh in consideration of lives lost and damage to property. To avert these losses, studies (e.g., Azad et al., 2020; Hadi et al., 2021; Parvin et al., 2019) have confirmed that the most important cyclone mitigation measure is to temporarily evacuate the vulnerable population on issuance of a warning and protect them by arranging shelters with adequate facilities. It is necessary to better understand people's protective actions and hazard decision-making in pursuing effective and efficient evacuation inclusive of safe sheltering. In this pretext, Raj et al. (2010) argue that broadcasting information about available emergency aid resources, especially through timely warning bulletins, helps people protect their lives and property from cyclones.

Research findings from Alam and Collins (2010); Raj et al. (2010); and Paul et al. (2010) similarly ascertain that community engagement in evacuation, such as volunteers with the Cyclone Preparedness Programme (CPP), remains a major focus and self-reliance is considered the key to preparation, response, and recovery from cyclones. It is, however, evident that efficient warning message dissemination through broadcast media, radio in particular, to people at risk is an important precondition for disaster preparedness. In performing such dissemination, media – especially community radio within small communities – plays a crucial role in

developing countries (Ahsan & Khatun, 2020; Hibino & Shaw, 2014; Selvaraj & Kuppuswamy, 2019; Sen, 2020). For instance, Selvaraj and Kuppuswamy's (2019: 103) research on the *Peridar Kaala Vaanol*, station in Tamil Nadu, India, found that community radio stands as an irrefutable medium of disaster communication, especially to the vulnerable and socially excluded and economically disadvantaged.

Similar to this, Raj et al.'s (2010) study found that boosting people's confidence can help reduce the possible death toll from a catastrophic cyclone and tidal bore in Bangladesh through providing early and simple-to-understand radio warning in the local dialect. The study argues that successful public awareness programs aimed at changing the mindset and developing the capacities and skills of people might reduce the number of lives and property lost substantially. Following such a reference, the densely populated and disaster-prone Bangladesh has considered early warnings and alerts to be critical for mobilizing human and other material resources to manage cyclone emergencies (Ahsan et al. 2020). In response, this study examines the broader influence of four community radio stations' programs in the overall impact on evacuation and preparedness strategies.

Based on a month-long observation of people's behavior during cyclones as well as 16 in-depth interviews with radio station managers, listeners' club members, and non-listeners across the coast, this study finds that vulnerable people in remote coastal areas and offshore islands continue to rely on community radio for information about cyclone preparedness, evacuation, and sheltering. This study also revealed that the distinctive practice of regionally broadcasting early warnings in local dialects has improved information clarity, reliability, and understandability of the messages. Community radio's delivery of warning messages has aided those in danger of cyclones in making the necessary preparations. Together these issues appear to have helped community radio listeners incur a significantly lower degree of losses than non-listeners.

Furthermore, the study demonstrates how community radio has effectively increased disaster preparedness in cyclone-prone coastal Bangladesh, leading to significantly fewer deaths for community radio listeners. Finally, community radio stations are not mere providers of cyclone preparedness information but rather the empowerment agent of the community in multitudinous aspects, particularly by building capacity that comes in handy during cyclones. This study also shows that the programmatic and capacity-building efforts of the community radio stations had a tangible impact in terms of putting into place and strengthening community preparedness mechanisms in cyclonic disasters. On the flip side of the aforementioned prospects of community radio, several challenges were also reported by the respondents, namely, limited network coverage, signal dropping, formal language (with technical jargon) in early warning messages, and perceived credibility of warning, which need to be addressed when community radio is engaged to minimize the loss of lives and property from cyclones.

Cyclones and Evacuation in Bangladesh

The Bay of Bengal in the Indian Ocean is a hotspot for forming tropical cyclones, with 10% of the world's cyclones originating there on average. Cyclones pose a serious threat to 27 million people living along 700 km of Bangladesh's coastline. Bangladesh has had at least 70 of these severe cyclones since 1965, which typically occur every 4 and a half years and go into category three or four on the Saffir-Simpson scale. Cyclones *Bhola* (1970), *Gorky* (1991), *Sidr* (2007), and *Aila* (2009) are among those that have wreaked havoc on coastal Bangladesh, claiming lives and causing significant property damage (CRED and UNDRR, 2020). During the 1970 and 1991 cyclones, the Bangladeshi coast had lost approximately half-million and 138,000 people, respectively. However, several years later in 2007, cyclone *Sidr* hit resulted in the death of 3460 people. Following cyclone *Sidr*, the deadly cyclone *Aila* struck Bangladesh's southwest coast in 2009 and killed 190 people. Bangladesh, despite facing cyclones *Roanu* in 2016, *Mora* in 2017, and *Title* in 2018, continued to experience fewer casualties. More recently, *Amphan*, a category one cyclone that made landfall on May 20, 2020, affected 2.6 million people, destroyed 55,767 homes, damaged 76 km of embankment, and destroyed 440 km of road across more than 19 districts but only claimed the lives of 22 people. The decrease of losses from cyclones confirms that Bangladesh has developed a workable disaster management system that incorporates a set of mechanisms and procedures (Ahsan & Khatun, 2020).

Despite significant improvements in the disaster response infrastructure over the last three decades, Ibrahim et al.'s (2019) study notes that shelter evacuation rates are still low. Ahsan and Khatun (2020) and Ibrahim et al. (2019) showed that jerry-built roads, a fear of theft, a lack of belief in and mistrust of warnings, ignorance of threats, and the poor condition of cyclone shelters are the main deterrents to evacuating during cyclones. Additionally, people's decisions about whether or not to leave their homes during the warning times were influenced by past experiences with warning failures, superstitious religious beliefs, fatalism, and safety concerns for women. Hadi et al. (2021) have found that most people are still taking a "wait and see" approach mainly due to fear of losing property. The preceding study results by Raj et al. (2010: 2) support the statement that "cyclone preparedness and evacuation are not primarily about awareness." Other factors that affect how individuals respond include housing type, individual economic and social standing, where cyclone shelters are located, level of education, prior experience, media availability, neighbors' influence, and age.

Hadi et al. (2021), however, compared people's evacuation to cyclone shelters in four different catastrophic cyclones (*Gorky*, *Sidr*, *Aila*, and *Amphan*) and argue that despite significant improvement in disaster management in Bangladesh, factors influencing noncompliance with evacuation orders have remained largely

unchanged over the last three decades. Studies (Hadi et al., 2021; Ullah, 2020), however, considered that early warnings (with preparedness instructions), which are typically disseminated through media channels such as television and radio, or warning flags, megaphones, sirens, and going door to door to alert people, are major effective tools of preparedness for cyclone hazards. After delivering warnings, the media might persuade people to seek refuge in cyclone centers built along the coastline zone.

Studies and surveys (e.g., Parvin et al., 2019; Paul et al., 2010) on the devastating cyclones of 1991 and 1997 show that radio and television warning transmission played a significant role in reducing the number of cyclone and tidal surge deaths because the affected populations were able to make adequate preparations after listening to both regular and special weather bulletins. For instance, Cyclone *Aila*, and its loss of 190 people, confirmed that effective early warning systems, special cyclone bulletins, and evacuation measures seem to have saved countless lives in this event. Considering the effectiveness of warning announcements through radio and television, the government of Bangladesh has placed broadcast media at the center of its disaster preparation plans (GOB & MODRM, 2017; UNDP, 2014).

Cyclone Warning Campaigns and Peoples' Responses

The Bangladesh government has given the broadcast media a number of chartered duties that are to be carried out before, during, and after disasters under the Standing Order for Broadcast Media 1985 (last updated in 2010). Radio and television operators are obligated to uphold these obligations during each stage of cyclone disaster management in collaboration with the Bangladesh Meteorological Department (BMD), Storm Warning Centre (SWC), and Ministry of Disaster Management and Relief. In addition to this, Bangladesh has improved disaster management through the construction of shelters and evacuation plans, the modernization of early warning systems, the building of coastal embankments, the preservation and improvement of coastal forest cover, and community-level awareness campaigns (Haque et al., 2012; Paul & Routray, 2013).

Although around 0.7 million deaths have been recorded in Bangladesh over the last 50 years due to cyclones, the decrease of causality data from recent cyclones encourages the international community to consider that Bangladesh has become quite successful in cyclone early warning dissemination and reducing the number of human causalities. Studies by Hadi et al. (2021), Paul and Routray (2013), and Ullah (2003) have confirmed that the lower cyclone death toll in Bangladesh is primarily due to improvements in early warning systems and prompt information

dissemination. Despite these advancements, millions of isolated coastal residents remain outside the reach of mainstream media due to poverty and illiteracy. It makes sense that a sizable portion of the population has yet little to no access to broadcast media.

However, researchers over time (e.g., Alam & Collins, 2010; Parvin et al., 2019; Raj et al., 2010) have found that the reasons for refusing to evacuate to a shelter during a cyclone, the key cause of death, are due to fear of burglary and theft, disbelief of warnings, lack of shelter in the vicinity, poor condition of shelter, poor road network, religious beliefs, illiteracy, conservative and superstitious beliefs, confusion, distance to the cyclone shelter, misinterpretation of warnings, cultural issues, and past experiences of the failure of early warnings or false warnings. For instance, Ibrahim et al. (2019) examined the reasons for nonresponse during the warning periods and obtained a comparative picture of three recent cyclones over Sandwip island: cyclones *Mahasen* in 2013, *Roanu* in 2016, and *Mora* in 2017. They found that the majority of residents (around 80%) received warnings through megaphones, followed by radio, mobile phones, and other sources (neighbors and friends).

Raj et al. (2010: 5) study reveals that although radio (75.3%) is a significant source of information on appropriate preparation measures, around one-third (31.6%) of respondents faced difficulties to understand the cyclone signals (22.3% partially and 9.3% failed) and 30.5% showed reluctance to heed warnings. Lack of acquaintance with the technical jargon used by the media (14.3%), unclear understanding of the distinction between river and sea ports (14.3%), misunderstanding of the signal (24.0%), and general lack of concern (8.0%) were the causes of their incomprehension. Therefore, the traditional cyclone warning signals broadcast through media in Bangladesh are heavily criticized by disaster management agencies. For instance, quoting UNISDR (2007), Ullah (2020) acknowledges that disaster management organizations both at home and abroad assert that the majority of coastal residents are unable to understand radio and television broadcast warning announcements for technical reasons; one of the most frequently cited reasons is the use of “polished” “textual” language in the bulletins along with “meteorological jargon” (UNISDR 2007).

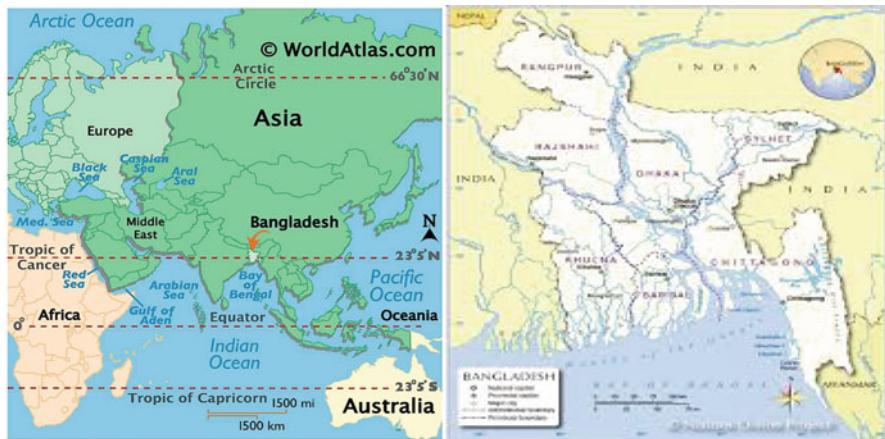

Most adults and women are illiterate in Bangladesh’s coastal region and offshore islands and are not familiar with the language used in warning bulletins and consequently fail to recognize the impending threat (Paul & Routray, 2013). Subsequently, low literacy levels are a significant variable in mediated cyclone warning messages’ success (or lack thereof). Raj, Ullah, and Akhter’s study (Raj et al., 2010) noted that 19.3% of the respondents has acknowledged that they are unfamiliar with the technical jargon used in media announcements and warnings about cyclones. Within this pretext, Ahsan and Khatun (2020), utilizing the Protective Action Decision Model (PADM) created by Lindell and Perry (2012),

address the problems entailed in overlapping processes before hypothesizing how information sources may assist people at risk in getting ready for or selecting protective measures in times of threat. They have discovered that community radio listeners suffer significantly less economic loss than non-listeners do ($\chi^2 3:11$; $p < 0:003$). Under these circumstances, this study intends to unearth the success and constraints of community radio in mitigating cyclone disaster-related warning effects through a qualitative inquiry.

Study Design and Community Radio Studied

To date, 19 community radio stations are in operation across Bangladesh. Nine of the current stations provide news, infotainment programming, weather forecasts, and cyclone hazard early warnings to roughly 2.3 million at-risk residents throughout the coastal zone (BNNRC, 2022). Three key preconditions – (a) the station must be located in a cyclone-prone coastal zone; (b) one community radio must be situated on an offshore island; and (c) one must be government-run community radio station – were followed to select radio stations for this study. With these preconditions and considering the quota (geography and ownership) and purposive (easy to reach and geography coverage) sampling method, four community radios, namely, Lokobetar, Radio Sagor Dwip, Krishi Radio, and Radio Naf (located on the map), were selected.

Lokobetar started airing in 2011 and is the first Bangladeshi community radio station located in Barguna, a deadly cyclone-prone southwestern district. A nonprofit media research and training organization – Mass-line Media Centre – established this station with Danish aid agency DANIDA. Lokobetar reaches around three million listeners in Barguna and its two surrounding districts and airs 6 hours of programming daily from 3 to 9 pm (for detail, <https://lokobetar.com/>). The second is Radio Sagor Dwip, situated on the island Hatiya in Noakhali, a southeast district of the country, which has been established to assist marginalized rural populations in disaster management and spark democratic processes including ongoing social development initiatives on the island. Dwip Unnayan Songstha (Island Development Association) in collaboration with Japan International Cooperation Agency (JICA) established the station (for detail, <https://radiosagordwip.net>).

COMMUNITY RADIO IN BANGLADESH

Study map: prepared by the author from Nation Online Project

Krishi Radio (farm radio; full name is Community Rural Radio) launched in 2012 at Amtali of Barguna district, with financial assistance from the Food and Agricultural Organization (FAO) and under the direction of the Agricultural Information Service (AIS) of the government of Bangladesh. The station has a broadcast capacity of 50 km and 8 hours of programming (from 9:00 am to 11:00 am and from 3:00 pm to 9:00 pm) with an estimated 175,000 listeners each day (for more detail, <http://www.ais.gov.bd/> and <http://www.shongjog.org.bd>). Radio Naf is located in Teknaf, in the extreme southeast corner of Bangladesh, near the border between Bangladesh and Myanmar. Approximately 1.5 million people within a 50 kilometer broadcast radius can hear this station, which was established by the local NGO Alliance for Cooperation Legal Aid Bangladesh (see for more detail, <http://www.radionaf.com/>).

The empirical data for this study is collected through intensive observations of the radio stations' activities, examining the program contents and people's response during cyclonic situations in real time. The study also conducted 16 in-depth interviews with all managers of the stations studied as well as people living in the community, station volunteers, and cyclone victims across the study areas during Cyclone *Bulbul* (November 2019). The data has been analyzed from the observation notes regarding warning bulletin dissemination and people's responses. Multiple coding of the interview transcripts (lasting between 40 min to an hour each) also contributes to understanding preparedness activities for people at risk in cyclone-prone areas. The transcripts of the interviews were thematically analyzed by two cycles of coding (Saldaña, 2016). This process involved open coding, identifying themes, clustering themes by patterns, and distinguishing meaning from these patterns. Applying all these methods, the results are summarized under four broad themes – (a) community preparedness, evacuation, and safety; (b) community radio intervention: cyclone campaign strategies for preparedness activities (c) safety from cyclone and the community radio, and (d) community radio and capacity building.

Results and Findings

Findings show that just before and during cyclone landfall, community radio stations broadcast cyclone alerts, preparedness messages, and evacuation directions that are friendly to their listeners. All radio stations under this study abandoned the regular broadcast schedule and broadcast hourly warning updates as well as religious sermons (*Humd* and *Naths*). The findings further reveal that community radio stations have a noticeable impact airing round-the-clock warning bulletins during the pre-cyclone emergency period. Stations included in the study broadcast warning bulletins, publicized emergency crisis management meetings, and provided reassuring and composed evacuation announcements in order to dispel myths, confusion, and rumors among at-risk people. In addition, the community radio

stations provided timely and accurate updates on the level of damage incurred and produced programs in which victims can express themselves first hand, established contact with the meteorological office, and broadcasted regular weather bulletins. However, due to insufficient logistics and a lack of production experience for pre-cyclone programs, the cyclone broadcast programs were unable to garner enough attention from all coastal residents.

Observation and in-depth interviews confirm that community radio campaigns have the capacity to avert immediate danger from cyclones and tidal bores. However, community radio stations cannot be completely effective due to lack of adequate training for broadcasters. The results of this study further confirm that listening to cyclone-related radio programs on state-run and community radio stations significantly influenced preparation efforts aimed at minimizing losses.

Furthermore, the empirical evidence reveals that those who are vulnerable may easily comprehend the warning messages that are broadcast by local radio stations in various coastal regions, enabling them to be well-prepared. Their dependence on alerts, hazard-related knowledge, and resources led to a reduction in the severity of tropical cyclone losses.

Community Preparedness, Evacuation, and Safety

People across the coastal region and nearby islands (chars) generally follow media announcements in order to learn basic information (awareness) about impending cyclones. It has been found that people in a high-risk zone (typically within a kilometer from seashore) respond more quickly to prepare by storing drinking water, securing dry food, and charging flashlights and cell phones ahead of those who reside inland. This study has also noted that compared to villages in clusters, people who live in solitary and dispersed settlements are more vulnerable. In addition, people living outside the cross dam (a protected earthen dam averting surges of water coming inside villages) are most vulnerable across the areas studied. People in those areas believe that cyclones are acts of *Allah*, and thus they follow the “wait and see” approach, a strategy to determine whether or not they are serious enough to seek shelter. Despite this, many people abide by government and non-government cyclone management authorities’ advice to prevent any casualties; people recall CPP volunteers’ instructions as their safety net during prior cyclones. Narrating her preparedness activities, Kulsuma Khatun (42) a widow living at Gollahkhali village at Hatiya Island says:

After hearing a cyclone (tufan) warning on the radio, I seek advice from neighbour and call [Mobile call] my son who is living in Feni town. Following advice from my neighbour and instruction from my son, I ask my daughter in law to tie up all valuable belongings [ornament, land records and cash mainly] of my family. In case of moving to the cyclone shelters, I always follow neighbours. In most cases, I do not feel to move to the cyclone shelters . . . only when the Red Crescent [CPP] volunteer urges me to evacuate [from home] repeatedly, I start moving.

Regarding the preparedness Nizam Mridha (38), a day laborer working on a boat on the river Paira from Dhalbhanga village, 8 km away from Lokobetar station, says:

Two days before the cyclone (bonna) hit I learned from the radio that danger signal number five was declared, and the announcement advised us to evacuate to the local cyclone shelter within the next 12 hours. I decided to wait for another day as moving to a cyclone shelter was challenging. So, I asked my family members to depend on Allah and seek refuge from my neighbors who have a brick house rather than move to a nearby cyclone shelter, which is around a kilometre away from our house while the neighbor's house is within a 10 minute walk. I am also concerned about the safety and purdah issue of the female members of my family.

These experiences ascertain that preparedness activities and taking refuge to the cyclone shelters depend on (a) God's mercy, (b) the availability of credible warning messages, (c) means available for refuge and safe spaces for female members of the family, and (d) getting instruction either from neighbor or male bread-earner and red crescent CPP volunteers. Here another important issue has been noted – cyclones are known by different names – *Ghurnijhor* as conventional Bangla, *Tufan* at Hatiya, and *Bonna* in Barguna.

Community Radio Intervention: Campaign Strategies for Preparedness Activities

The examination of the program content demonstrates that all the investigated community radio stations frequently broadcast programs about cyclone preparedness and evacuation. Programs about cyclones include drama (play), evacuation and safe sheltering instructions, and folk music that are very popular. The news and program structure, however, appear to be a copy of traditional radio. For instance, Lokobetar airs special 30-minute programs on cyclone and includes weather bulletins in its newscast. The programs include (roughly translated) Tales between Grandma and Grandchildren (Nani-Natir Kischa) every Saturday between 4:45 and 5:30 pm and Talk of the Shore (Upokuler Kotha) every Sunday between 7:45 and 8:30 pm. In addition, the station continues to run special weather briefings every half hour, while interrupting other regular programming as scheduled after receiving a cyclone warning alert message from the SWC. Immediately after the SWC issues warning signal numbers four and up, the station abandons all other programming and begins broadcasting evacuation instructions along with bulletins that include information on risk perceptions for hazards, pre-cyclone actions, whether to seek shelter during a cyclone, how to get there, the intensity of the wind speed, and other pertinent information. Along with these the station also starts the religious program (recitation from the holy Quran, including Islamic lyrics – *hamds* and *nath*).

Sagor Dwip radio station focuses on cyclones and river erosion throughout the year because of its location on an island. The station broadcasts a magazine style

(15-minute duration) program every Saturday and Wednesday at 11:30 am that includes “Come, Learn and Keep Safe” (*Esho Jani O Bachi*) which consists of personal accounts of cyclone victims, their coping mechanisms, and tips for finding shelter and highlights community radio’s role in warnings. This station airs a weather bulletin in the evening, considering its listeners’ needs and schedule. Krishi Radio, on the other end, focuses on agriculture, including soil erosion, the safety of seeds and seedlings, planting, and safety from insecticides and fertilizer. It broadcasts special programs on cyclones – The Disaster and We (*Durjoge Amra*) and Fisher’s Life (*Motsho Jibon*). After getting cyclone warning signal alert number seven, the station ceases its usual programming and broadcasts the special weather bulletins as instructed by SWC. The station’s national coordinator, Dr. Md. Zahangir Alam, narrates, “Krishi Radio FM 98.8 broadcast 92 consecutive hours of special programmes for the victimised people, their shelter and specifically to save their agriculture and the role was ‘remarkable’ indeed during cyclone *Mohsen* in May 2013.”

Radio Naf broadcast their 30-minute program “Learn and Live” (*Jene Nijeke Roksha Kori*), a talk show on disaster preparedness, mainly for landslides and cyclones. The Saturday program focuses on cyclones simultaneously with the same title and repeats on Monday. According to Harun-ur-Rashid, the station manager, “our station broadcasts regular weather bulletins both in the morning and evening ... [but] we take special care in broadcasting news and bulletins during the cyclonic period with a special attention to the inhabitants of the island Saint Martin through local dialects.”

The community radio policy [Clause 8.10] directs broadcasters to use formal Bangla, while incorporating regional customs and culture. However, the demand to broadcast warning bulletins in the local dialect is always emphasized, and community radio stations suppose to broadcast warning bulletins in the local dialect. Despite having the direction and request from locals, this study has noticed that the program format and language and textual analyses of news bulletins and special programs are being broadcast in formal Bangla, following the style of the state-run radio – Bangladesh Betar – and commercial radio stations’ formats. The news and warning bulletins in the local language are not possible to broadcast regularly on community radios. The reason, according to the station manager of Radio Naf, Harun-ur-Rashid, is that “we adhere to the traditional radio weather bulletin framework and receive instruction from BNNRC in the preparation of the weather bulletins.” Lokobetar station manager Munir Hossain Kamal also admits that writing news in the local dialect is difficult as there are no specific synonyms for expressing some words in Bangla. However, all cyclone-related programs try their best to broadcast by using local languages (Lokobetar uses Barisali language, Sagor Dwip uses Noakhalian dialects, and Naf uses Chittagonian and Burmese languages) but could not do so adequately on their own and engaged volunteers to do so. Being a state-sponsored station, Krishi Radio uses the formal Bangla language in programming except in special cases.

Safety from Cyclone and the Community Radio

The dependency on community radio for cyclone warning is high among the coastline people where electricity and other media are not available. It has been found that women are comparatively more concerned for the safety of their family members and including valuable belongings (e.g., national ID card, land documents, cash, and ornaments) than of their counterpart male, and they rely most upon community radio instructions when the safe sheltering is concerned. Madhabi Bala Sheel (45), a Sagor Dwip listener's club member from Purba Laxmidia village on Hatiya, acknowledges the value of radio announcements:

My husband asks me to keep this radio safe; he repeatedly says not to hand it over to anybody after there's a cyclone warning alert. . . . If the Dwip Unnayan take it [the radio set] back, I must buy one to keep myself updated on cyclone preparation activities.

During inclement weather, electricity has usually been cut off. As such, people living in isolated and distant locations consider community radio to be better option for having a credible cyclone warning message. Previous studies confirm that the credibility of a cyclone warning message is influenced by its content, characteristics, sources, conformity with the receiver's preexisting views, and previous exposure to similar warnings. Dipali Rani (46), a well-off family from the Dhopar Hat area in Amtali Sadar, mentions:

A day before the cyclone's landfall last time, I realised that the radio announced danger signal number four, and I got confused hearing the danger signal number six just a few hours ago. I discussed my confusion with my neighbor, and she confirmed that the signal number was four on that day, which made me more confused. Now, I tune into Lokobetar for any credible information regarding the cyclone.

In every case, this study has observed that the cyclone bulletins through community radio hold strong credibility because these stations mentioned the conditions from the specific affected villages and mohallas. People consider that community radio bulletins broadcast in local dialects become more reliable among people because they are easier to understand and more relevant to their personal experience. Describing the response from listeners, Sagor Dwip station manager Papia Sultana asserts:

I know that the local dialect is more effective in connecting with local people [through community radio]. Thus, my station prepares programme content as necessary for our people. More so, all volunteers and I were born and brought up here [on Hatiya], which is always a cyclone victim. Thus, we focus on the local language even though we cannot write in most cases the script in the local dialect.

All special weather bulletins, according to the Standing Order for Disaster (SOD), must include the location of the cyclone, estimated central pressure, direction and speed of movement, maximum sustained wind speed, the radius of maximum

sustained winds, areas likely to be impacted, and the approximate time gale-force winds (speeds of more than 32 mph or 52 kph) will begin to blow. They must also include the maximum wind speed, expected storm surge height, and areas most likely to be impacted. But government-run community radio is a different story. In reality, it is found that technical weather language frequently prevents community radio's special weather reports from providing all of this information.

This study has noted that the perceived credibility of information is a crucial asset during the cyclone, because it aids in preventing the spread of rumors that might exacerbate an already chaotic situation. Similarly, bulletin announcements in the local language with local jargon or dialect usually make the listeners more comfortable and the information more trustworthy as a result. By serving the informational needs of the impacted community throughout the coastal region and speaking the local languages, the community radio station becomes into a stand-alone medium during cyclonic disasters. In other words, the language, technical jargon, understandability, and sufficiency of the information in the warning message can all have a significant impact on how people perceive the risk and grasp the information contained in it.

Community Radio and Capacity Building

In Bangladesh, the cyclone risk reduction (CRR) strategy strives to lessen the harm that cyclones bring. As a component of CRR, cyclone preparedness helps those who are vulnerable comprehend and assess the level of danger, prevent it if feasible, lessen its effects, and manage the long-term psychological, social, and economic repercussions. A reliable and effective early warning system gives timely information that can be trusted, enabling those who are at risk to understand the severity of an impending cyclone's risk and take the appropriate precautions to minimize losses. Aspects of the warning network including the information's source, the channel's qualities, and the warning message's features have an impact on readiness by affecting how at-risk individuals behave to protect themselves during a disaster event. The proximity of a person's residence to the coast can increase the risk of coastal flooding exponentially.

It is observed that community radio has left its footprint on vulnerable communities by empowering them with the necessary knowledge they need to prepare and respond through round-the-clock emergency instructions prior to an impending cyclone. People relied more on the forecasts and recommendations provided by community radio due to the simplified delivery (i.e., minimizing scientific jargon) in regional dialects and names of specific locations familiar to listeners. In typical situations, vulnerable individuals tune in to the news three to five times per day. The at-risk people informed they prefer listening to the high number of special bulletins that community radio stations broadcast alongside news during emergency situations.

The field observation shows that audiences comprise students, senior citizens, farmers, small traders (makeshift vendors), tea stall owners, day laborers, rickshaw

pullers, votvoti drivers (locally made vehicle), women, young girls, children, fishermen, and NGO workers. When traveling throughout the locations under this study, it was found that a good number of people have heard the name of *Lokobetar* community radio station and often listened to its programs. Young students from *Lotabaria* and *Kakchira* villages, around 15–20 km away from station, and *Dhalbhanga* village, an 8 km away from district town, were more enthusiastic about the community radio program. The elderly and women have some knowledge of the station and not listen to *Lokobetar* program except during cyclone. Nizam Mridha (38), a day laborer at *Dhalbhanga*, says, “I follow *Lokobetar*’s instructions during the cyclone. My confidence was raised by the program during such a traumatic event.” Similar to this, Shahan Ara, a housewife from *Urashitola* village [15 km from Krishi Radio station], says:

I always listen to its [Krishi Radio] programming. Instructions relating to cyclones are incredible. May Allah live long the people from this station, because, through their instructions, I [as a woman] know now what needs to be done to prepare during the cyclone.

To boost the contribution of community radio in cyclones, listeners’ clubs install radio transistor at makeshift shops across villages and keep those transistors on throughout the cyclone period for better reach among the most vulnerable. When traveled across areas studied, for instance, it had been noted a good number of radios put out with a loudspeaker at *Kachuptra* bazaar (market) in Amtali (Krishi Radio coverage area) and *Nalchira Haat* [weekly marketplace] on Hatiya. However, those were not used and maintained properly when it was needed. Sagor Dwip station manager Papia Sultana insists, “maintenance training for listener’s club members and special training for volunteers, including us [the station management], is important.” She has confirmed even that most volunteers are not aware of the standing order.

The on-site field observation notes that BNNRC offers volunteers and staff members of the investigated community radio stations a series of courses aimed at increasing their capability. According to official data, workshops on developing content on cyclones and other topics emphasized community involvement and participatory formats. It has been found that the stations under study are staffed by over 300 volunteers, the majority of whom are male and female college and university students. Their engagement is considered a valuable asset for community radio stations. Despite the lack of data on their level of involvement with these stations during cyclones, it is inferred that a significant number of them work voluntarily.

Discussion

The cyclone warning system for coastal region of Bangladesh has been improved through an adaptation program. As a result, cyclone-prone coastal people can receive early warnings and forecasts during the cyclone seasons (March–May, October–

December). People living along the shore who are vulnerable to cyclones can therefore get predictions and early alerts throughout the cyclone season (March–May, October–December). However, early warnings are not enough to minimize damage; warning messages' timing, accessibility, and credibility are important. For instance, if a person or household at risk gets the warning right before the cyclone makes landfall, they won't have enough time to take the necessary precautions (e.g., evacuation and sheltering). Furthermore, Ahsan and Khatun (2020: 7) note, "if one warning turns out to be wrong or misleading, people will consider future warnings to be false alarms." To avoid confusion, the Bangladesh government, IFRC, and BDRCS advise adhering to the standing order standards, while promoting programming and broadcast bulletins relating to cyclone preparedness. Similar to how community radio plays a key part in disaster risk reduction, the National Disaster Management Policy from 2015 emphasized outcome-based measures for disaster preparedness and mitigation that are in line with local culture, context, and values.

Local and international agencies (GOB, 2020; UNDP, 2014; UNISDR, 2015) considered cyclone-related losses in lives and property could be minimized significantly through structural and nonstructural interventions. The construction of infrastructure for the first involves investments in the billions of dollars, and Bangladesh has made significant monetary contributions in this field. However, authorities prefer that Bangladesh should use a combination of hardware and software and choose less expensive nonstructural measures in response to cyclone risks because it is a resource-constrained and highly cyclone-prone country (Raj et al., 2010). A campaign by community radio is one of the best options as far as nonstructural measures go. Similarly, studies by Choudhury et al. (2019) and Paul et al. (2010) offer important insights into the reasons why cyclone victims are unable to take part in evacuation efforts. Three categories of inabilities are identified by Paul et al. (2010: 89–90): (a) factors associated with cyclone preparedness and infrastructure, (b) sociodemographic and socioeconomic factors, and (c) factors associated with hazard perceptions and attitudes. The trustworthiness of the warning systems was mentioned frequently among the cyclone preparedness considerations. The warning systems were perceived as being unnecessarily complex by some interviewees, inadequately given by others, and simply untrue by many others.

Community radios, in such a situation, are recommended to provide adequate space for victims and community participation and to broadcast warning bulletins in local dialects. In addition, a supplementary explanation of warning alert or instruction in plain language and the relevant local dialect is recommended, and the need for trained volunteers and skilled human resources for community radio remains urgent. Field data shows that although the studied community radio stations provide space for volunteers from within the community to participate and raise voices, more vulnerable cyclone-affected people, in particular, do not get the scope to share their experience on cyclone preparedness. Often only experts have the opportunity to speak on behalf of victims and those with lived experience.

The stations studied tried their best to value listeners, but station executives do not provide listeners' space to participate in programming more proactively, often citing adequate financial capacity and travel allowances as a barrier. This study feels community radio stations need to focus more on participation of community

members with the station. Participation in activities could help ensure the level of understanding necessary and the strategy needed for programs and bulletins to effectively broadcast and to prepare content and boost the morale of vulnerable people. In doing so, station managers need to adopt proactive initiatives through training community members on disaster broadcast with a manual that will work as a permanent resource for the station.

Overall, the empirical findings suggest that community radio performed better in terms of fewer casualties and increased reliance on risk awareness during tropical cyclones that made landfall across the vulnerable coastal region of Bangladesh. Community radio broadcasts warnings firstly on a regional scale, frequently explaining the SWC's warning messages in local dialects for better understanding; second, these stations prepared programs that focused on local characteristics, which helped vulnerable people to understand cyclone risks and have an enhanced awareness of these impending risks. These are the plausible explanations for this. Finally, because local residents ran these radio stations, consideration of regional advantages and disadvantages for cyclone preparedness was ensured.

Conclusion

Cyclones disrupt the normal functioning of a community across the coastal areas of Bangladesh. When an impending cyclone disrupts normalcy, the need for information will increase. As the people at risk depend on the media for timely and credible information about the advancement of an imminent cyclone, a community radio station can stand as a source of timely and credible information, thereby empowering the communities with knowledge and confidence to make decisions about evacuation and safe shelter. Community radio stations can deeply recognize a community's vulnerability and their information and knowledge needs and pave the way to build resilience. This indicates that community radio possesses the potential to minimize the damage and loss of life and property by learning how to respond to cyclones.

The findings of this study indicate that disaster preparedness for cyclones, particularly in terms of reducing cyclone-induced losses, has been significantly influenced by listening to disaster-related programs on both state-run and community radio. Even so, it has been noted that the distinctive feature of localized early warning broadcasting in regional dialects has improved the understandability, information clarity, and dependability of the warning messages delivered by community radio, helping at-risk residents in making the appropriate and necessary preparations to deal with cyclones. Furthermore, community radio appears to help people at risk to enhance their knowledge and awareness on disaster preparedness, which has allowed them to lessen loss over the last decade and adds some new dimensions in addressing cyclonic disasters that cause catastrophic losses of lives and property in the coastal region of Bangladesh. This study furthermore notes that community radio stations in Bangladesh differ from state-run (including Krishi Radio and Bangladesh Betar) and commercial broadcasters in their processes, approaches, styles, and content since they are community-driven, volunteer-run, not-for-profit organizations.

Community radio stations can also create a rigorous and suitable strategy to broadcasting about cyclones by disseminating reliable information through regional languages and dialects, challenging the hegemony of the mainstream, both commercial and state-owned media, and its programming practices. For such, authorities must put safety measures in place for station staff, schedule station briefing meetings to ensure effective warning signal distribution, and keep a close eye on all official announcements and activities of the national, local, and aid agencies from the ground up. In such a way, community radio stations can be a valuable asset in the fight against cyclone losses. In doing so, three issues need to be addressed. Firstly, conduct in-depth research to understand the constraints and ways to navigate those constraints. Secondly, continuously train volunteers and station workers, and thirdly, prepare a manual for station managers and volunteers which would be a great resource to coordinate cyclone-related community radio broadcasts and response.

Acknowledgments This chapter is an outcome from a research on community radio and cyclonic disaster in Bangladesh conducted under the Hoso Bunka Foundation, Japan HBF Grant, no: 293071, 2017–2018 cycle, and I acknowledge my friend Dr. Mallory Peak for her kind comments of the initial draft and editorial cooperation in preparing this chapter.

Abstract

Environmental journalists play a considerable role in environmental breakdowns regardless of their reporting mode. The environmental stories taken by many environmental journalists over a period of time cover a vast area of consequences of environmental issues. The reporting of destructive environmental events like disasters is also no different. Disaster events can create unprecedented socio-environmental conditions which negatively impact society. Hence, pre-disaster communication can effectively communicate disaster risks before the disaster. Even in the disaster context, they should ethically report reliable and essential information on the disaster that occurred. When it comes to the post-disaster

context, the said journalists can effectively monitor rehabilitation and restoration of essential supportive mechanisms. Numerous political and economic forces can be seen in disaster contexts, and disaster events have been politicized due to those forces. Those forces can also influence the role of environmental journalists, and their representations may be biased in terms of disseminating sensitive information. Under this backdrop, the ecological journalist's role has been interrogated in various social settings. This chapter inquires about the status and role of environmental journalists in the disaster context, particularly in Sri Lankan disaster events. The present discussion creates a deliberative background that can be contributed to the augmentation of the discourse of environmental journalism in the disaster context.

Introduction

There is an ongoing debate on how mainstream media views itself and how sensitive its reporting is and its credibility among media consumers. It has opened an argument about what constitutes a “journalist” in the contemporary context. Also, it is significant to look into the facts of journalism and newsroom budgets, news trivialization, fragmented media sphere, and decreasing public confidence in the profession of journalism. Objectivity and bias, advocating ethics, and organizational agendas do impact journalism. Serving public interest with fewer biases has to be the main consideration of journalism (Vine, 2017, p. 43). A crisis of credibility and being hypersensitive might reduce professionalism of journalism and environmental journalism (Vine, 2017, p. 45). The trustworthiness of mainstream media is essential; otherwise, people tend to abandon traditional media. When a journalist tries to balance these aspects, she/he runs the risk of being blamed by the management for falling attention levels. However, credibility is a fact that cannot be left out under any circumstances. The connection between falling audience numbers and falling standards comprises other societal goals (Vine, 2017, p. 47).

According to Powers (2015, cited in Vine, 2017, p.48), changes in news media, advocacy, and technology are sparking growth in “NGO journalism.” New forms of journalism must ensure factual accuracy, fairness, and thoroughness. Journalists must not manifest their inherent personal, financial, or institutional biases (Vine, 2017, p. 48).

In some instances, journalists are excited to capture, pursue, and produce a unique story that has not been told before. They think that it will sharpen the importance of the news and theirs (Vine, 2017, p. 49), in the commercialized television world, the value of what journalists publish sway on entertainment value. The attractiveness of news tends to be painted with photogenic, articulate characters. In a way, the issue of “public interest” has seemed to have created a dichotomy between how journalists

see themselves and how the public might view them. There is an emerging trend that people are more likely to trust social media, which is a platform of news posted by people themselves than media or the government (Vine, 2017, p. 50).

According to Powers (2015 cited in Vine, 2017, p.51), journalism is converting to a platform for fundraising or misleading reporting, far from the core aims of advocacy groups. Credibility and fairness are profound values of journalism. Further, it seems that serious values of journalism have been compromised. It appears that potential solutions to the problems of journalists depend on the time and resources provided by their organizations. Hirst (2009 cited in Vine, 2017, p. 51) has spoken of the new possibility of “alternative journalism” as “a response to capitalism and imperialism as the global dynamic of domination and consolidation.” The other alternative to present-day journalism can be recognized as “citizen journalism,” which predominated during the Arab Spring. This citizen journalism is evident in places where paid journalists are afraid to report the realities of people’s lives. Other alternative forms of journalism can be recognized as radical journalism, critical journalism, activist journalism, social justice journalism, and advocacy journalism. Advocacy journalism is essential in the sense that the reporter intentionally and transparently adopts non-objective points of view on social or political issues (Vine, 2017, p. 51).

Careless (2000 cited in Vine, 2017, p. 52) describes that being faithful, accurate, credible and acknowledging the perspective do not ignore opponents of journalists, while neutrality in reporting is progressive. Advocacy journalism benefits both the host organization and the broader well-being of journalism. A national business review article about journalism at Greenpeace (Rotherham, 2017 cited in Vine, 2017, p. 52) claimed that the definition of journalism is broad and it has to be valued based on its merits. Plugging the significant fact of credibility and adapting to the digital environment while recognizing biases in traditional reporting are essential. “NGO journalism” is a debatable phenomenon. They should ensure factual accuracy, fairness, and credibility in their work. Advocacy journalism is significant to environmental issues and factors because it is far from being biased and mainstreaming working for the public interest (Vine, 2017, p. 52). To cite an example, campaigning organizations such as the Greenpeace has been quite active this field.

Environmental journalism is considered to be one of the most risky branches of journalism as the risk of being subjected to a high level of serious harm. Sometimes, it can result in the death of a person. The distinction between “environmental journalist” and “environmental activist” needs to be understood clearly. Environmental journalists in developing countries and developed countries, however, can be subjected to the same levels of vulnerabilities. Ecological issues are bound by immigration, racism, religion, and gender inequality, factors that often trigger the exposure to threats and harassment (Hiltunen, 2017: 69 cited in Freedman, 2020: 275). Environmental journalists around the world are at risk of being murdered, arrested, assaulted, threatened, self-exiled, embroiled in lawsuits, and subjected to harassment due to the exposure of influential business and economic interests encompassing political power battles, criminal activities, corruption, as well as other forms of politically, culturally, and economically sensitive factors

that they are working with. Environmental issues cover a large spectrum from indigenous rights to land and natural resources.

Environmental journalists face psychological and professional problems in reporting that include arrests, attacks, lawsuits, harassment, firing from job resulting in stress, trauma, anxiety, etc. These are both short-term and long-term effects on environmental journalists. There is no known professional (2009: 431–432 cited in Freedman, 2020: 276) body for environmental journalists, which can address these issues. Environmental journalists who had been in danger dealt more frequently with traumatized subjects; they, however, reported feeling better prepared to deal with the professional challenges. It is important to include environmental journalists' voices in research (Freedman, 2020: 276).

Physical insecurity combined with economic pressures limits serving adequately the public interest. There are five factors that influence environmental journalism which are social systems, social institutions, media organizations, routine practices, and individuals according to a hierarchy top to bottom (or macro to micro); these factors do have an impact on content produced by the journalists (Freedman, 2020: 277).

Social systems refer to ideological, economic, political, and cultural subsystems that influence news coverage of issues. The paradigms that they create are varied from country to country. It includes propaganda, nationalism, promotion, development, etc. Freedom of the press and nationalistic systems are crucial factors in this regard. Furthermore, environmental journalists are influenced by the obligation to work for pro-national interests in nationalistic systems.

There are three major institutions that influence social institutions, viz., the state, government, and official sources such as the media and non-professional citizen bloggers (Shoemaker & Reese, 2014: 97 cited in Freedman, 2020: 278). According to Powers (2016: 314 cited in Freedman, 2020: 278), contemporary transformations in media, politics, and civil society alter interactions between journalists, political elites, and civil citizens and it is the same in the environmental journalism, especially where NGOs and grassroots groups are playing important roles (Freedman, 2020: 278).

Media organizations in this regard refer to the consideration of the entire organization, and the fact of reporting content is not free from the organizational factors in which they work (Shoemaker & Reese, 2014: 135). Further, the fact of media organizations includes corporate and ownership policies, the structure of the organization, staffing resources, economic resources, media formats used to disseminate news and information, and similar and dissimilar roles of its reporters, visual journalists, and editors (Shoemaker & Reese, 2014: 164 cited in Freedman, 2020: 278).

Routine practices are developed from three sources, the audience, media organizations, and content suppliers, and routine practices are different from organization to organization. This is influenced by factors such as the organization's staffer's and freelancer's view on their mission, their self-perception, how they carry out actual reporting, the communication technology that they use, the type of the media platform and organization safety procedures, etc. (Freedman, 2020: 278).

Individual level refers to the professional and personal background of each journalist. Each journalist has their unique professional background, personal background, as well as demographic characteristics, experiences, attitudes, values, ethics, socioeconomic status, position that they have within the news organization, as well as competition (Freedman, 2020: 278). These five variables do have an impact on the contents that environmental journalists report (Freedman, 2020: 278). In this context, it is significant to have insights into the positive as well as negative facts with regard to journalism and specifically environmental journalism as we can see many natural and man-made disasters in the present world.

Environmental Journalism and Disaster Communication

Environmental issues are increasingly noticeable today, and a well-verses community is essential for sustainable ecological management. In other words, information and awareness of an environmental crisis can be conveyed to people through the media. Environmental issues expand from ground-level matters such as local garbage issues to global-level matters such as ozone depletion. Not everyone is fully aware of the details and perceived risks of environmental issues, and people need proper awareness to prevent ecological problems and mitigate their adverse effects. These practical underpinnings show that the media has become the utmost widely held and accessible communication medium for topics related to community well-being in a society characterized by constant technological development and distinguished by the significant consequences of globalization (Fallou, 2017).

The policymakers and the government need people to admit their influences on environmental issues. On the other hand, people should agree to follow the precautions in mitigating the effects of those issues. IBADRO newsletter (2020) defines environmental journalism as “current affairs journalism concerned with nature and the environment, particularly the impact of human activity on the environment, to increase public awareness.” Hence, environmental journalism plays a vital role in the fields of communication and media in terms of disseminating crucial ecological facts. “Journalism about the environment and climate change sits at the complex intersections between politics, business, science, nature, and culture, between the individual and the common and also between the local, regional and global levels” (Bodker & Neverla, 2013). Accordingly, the media can be supportive, complimentary, critical, or indifferent to emergency management.

Natural or man-made disasters are destructive events that are all too common in today’s world. The occurrence of any such disasters mentioned above would transform society in social and structural manner. According to Abeywardhana (2020), most disasters have environmental roots, and unnatural disasters have man-made causes but have intense adverse effects on the natural environment. Reporting catastrophic disaster-related information is a significant role of an environmental journalist, and then they become a substantial stakeholder in “disaster communication.” In other words, the risk of a disaster can be successfully conveyed to a target

population through an effective mode of communication. It may reduce the harmful effect of that event to a certain extent.

Niklas Luhmann (1992), while identifying ecological threats which are highly posing to the regular functioning of the current world, introduces the theory of environmental communication later on adopted to develop “disaster communication,” inquiring whether the communities can adapt to the ecological threats or not. According to Wahyuni (2019), “exploring Luhmann’s thought, thus, is an important means of providing an alternative explanation of the concept of ecological communication and its contributions to the understanding of ecological and disaster issues.” Overtly, “ecological communication” is Luhmann’s attempt to comprehend why society finds it challenging to recognize environmental risks and manage the environment effectively (Krippendorff, 1991).

Mass communication is inseparably entwined with disasters and hazard mitigation, and the role of communication in reducing the risk of disaster is manifold (Bhatti & Ariyabandu, 2002). According to Cate (1995), the role of communication and media in a disaster context can be divided into five (05) main categories:

- i. Technical communication system
- ii. Disaster-site communication
- iii. Organizational communication
- iv. Communication for scientific development and policy formulation
- v. Public education and communication

Each area enlightens the importance of the environmental journalist who can mediate in preventing the adverse effects of disasters through effective disaster communication. Since the twenty-first century is information-driven, advanced technologies and well-planned mechanisms can save people from being victims of disasters. The dissemination of reliable information before a disaster aims to encourage communities to take action to avert physical and psychological damages. In other words, effective warning mechanisms are instrumental in evacuating vulnerable groups moving emergency services and resources. According to Sharma (2005), effective disaster communication is based on three significant abilities:

- Largely technical and it has capabilities of identifying potential risk or the livelihood of a hazardous phenomenon occurring that threatens a vulnerable population.
- Ability to identify accurately the vulnerability of the population at which a warning needs to be directed.
- The ability that requires considerable social and cultural awareness in communicating information to specific recipients about the threat in insufficient time and with sufficient clarity that they take action to avert negative consequences.

By accumulating the above three capabilities, a communicative system can effectively function with the intervention of environmental journalists. Most of the time, the blame that comes to an environmental journalist dealing with disasters and

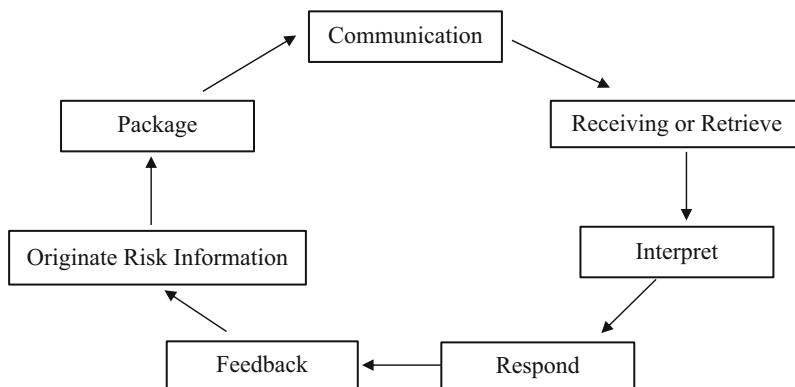

Fig. 1 The risk communication cycle. (Source: Bhatti & Ariyabandu, 2002)

any other type of environmental matter is that they are focusing on demanding matters instead of real matters that need attention. This is proven by Dynes's (1998) quote, "Media is potent in defining what a disaster is." He accentuates through the above quote that the media and the "pointers of media"/journalists can delineate an incident as a disaster or a typical scenario.

Furthermore, environmental journalism-based disaster communication has not constantly emphasized on highly vulnerable communities. It focuses on spontaneous news that can take the majority of the population (Smith et al., 2007). This further clarifies McKinzie's (2017) explanations. He highlights dominant elements in destructive narratives of journalists working in disaster contexts: the proximity to the disaster, "hero stories," religion, and resilience. Hence, the critical contention is about the environmental journalist in the disaster context that he extends his consideration only to "catchy" topics and not to the essential issues.

Disaster contexts always deal with specific risks that are perceived and unexpected. Therefore, the information that disaster victims receive is also bound to their risk, and it has been defined as "risk communication" in literature (Bhatti & Ariyabandu, 2002). Simply put, both Bhatti and Ariyabandu (2002) try to connect the process of conveying risk through communication to a cycle, and it is called "the risk communication cycle." The risk communication process starts from one whereby individuals hear a warning message to act or respond to its message to save their lives and property. This process includes three more steps, including the said components (Fig. 1). Those are as follows:

Risk communication is essential in preventing adverse effects of disasters, and the above cycle of risk communication can improve people's risk perception. Even though it consists of a message-medium receiver, disaster communication needs to be a quick flow of information like other communication forms. As Bhatti and Ariyabandu (2002) show, when the early warning is not available, the disaster event itself will become the origin of the information. Hence, disaster communication can effectively make people aware of such catalytic events in better pre-disaster and disaster context management. For that, the environmental journalist has a critical

role to play, as the piece of information that he delivers could influence thousands of individuals' lives.

Environmental Journalism in Sri Lanka

Sri Lanka is considered to promote participatory management to ensure sustainable human development through better communication and empowerment of communities. In Sri Lanka, *Sri Lanka Environmental Journalists Forum* (SLEJF) (please full form followed by acronym) is a prominent organization that works on restoring, protecting, and promoting environmental journalism and sustainable development rights of vulnerable population groups. Further, SLEFF is vital in working on challenges experienced by the people of the country. The priorities, according to them, are; (1) developing Millennium Development Goals (MDGs), (2) steps to achieve and adhere to those, (3) strengthening structures for enhancing the environment and sustainable human development, (4) creating a platform for the public for communicating more effectively with each other, (5) combine forces needed to make the country more peaceful place and also to strengthen individual's rights to freedom from want; (6) freedom to hear; (7) freedom to live in dignity (Senaratne & Wickramasinghe, 2000: 23–24).

The Central Environmental Authority of Sri Lanka has an Environmental Promotion Unit that works on environmental media-related matters. They are engaged in writing articles for newspapers on timely environmental trends, celebrating special environmental days, the management of different environmental issues, the preparation of press releases, providing coverage for different programs conducted by sections of the CEA, reviewing daily news in the media, providing news related to activities of the Central Environmental Authority to the Higher Management, and organizing preparations of replies to reviews for the media through coordinating with subject-related divisions. Further, they are engaged in organizing press conferences for media persons on special occasions, the evaluation of electronic and print media in Presidential Environmental Awards and organizing media programs on that, the media coordination of the Presidential Medal Program, the media coordination of the National Environmental Pioneer's camp and entering, and updating official web page and official Facebook page of the Central Environmental Authority.

Organizations involved in media journalism in the country are emphasizing, monitoring, and coordinating environmental education, public awareness, justice and practicing programs. They further engaged in developing special media training in environmental and developmental journalism. They have recognized human resources and parties nationally and internationally who are crucial in this process as a significant fact (SLEJF, 2000: 23–24).

Environmental journalists face many difficulties in Sri Lanka due to reasons such as editor's lack of knowledge on environmental issues and science, lack of support from editors, lack of facilities inadequacy of professional training, and pressure from the management of their host organizations. Especially with regard to issues such as

allocating space for their articles to publish in newspapers, influencers of advertisers and politicians, the complexity of environmental problems, and problems of getting information from sources. Further, in Sri Lanka, the field of professional ecological journalism is not yet well-established as there is no in-depth analysis of the environment in general. One primary reason for not prioritizing environmental journalism-related matters is that ecological journalism, which exists in the country's present context, has been created by non-governmental organizations with hidden intentions (Boyagoda, 2016).

Disaster Reporting in Sri Lanka: Two Cases of Sri Lankan Disasters

Sri Lanka is a country with an admirable climate. However, the climate has changed over the last 100 years. The temperature has risen by 1.06°C from the average temperature prevailing here. Agriculture is seen as the basic economic activity of the country. The increase in temperature, in general, is affecting agricultural production. The Northern, Eastern, North Central, and Southern Provinces of Sri Lanka have experienced continuous drought conditions for many years.

Analysis of the change seen between the average temperature over 1900–1917 and 2000–2017 suggests Sri Lanka experienced warming of around 0.8° over the twentieth century. This estimate broadly agrees with the temperature rise reported in Sri Lanka's NC2, which estimated 0.16°C of warming per decade between 1961 and 1990. Temperature rise has accelerated toward the end of the twentieth century (Second National Communication to the UNFCCC [NC2], 2022).

One of the major problems facing the world today is climate change. Changes in temperature and rainfall are caused by natural factors and human activities. Drought conditions are caused by declining rainfall and changing seasons when rainfall is available and rising temperatures. Drought and flood are the most important natural disasters in Sri Lanka. Drought is a condition in which the entire environment loses water and becomes completely dry, subject to high evaporation (Istiquar, 2013).

Drought is a characteristic of climate recovery. This is a phenomenon that appears in practically all climatic zones of the world with high and low rainfall. This is a temporary change of climate. In contrast, aridity is a permanent feature of the climate. It is restricted to low rainfall areas (Guide to Best Cultivation Practices for Drought and Floods in Sri Lanka, 2011). Drought has various impacts on the environment. Drought does not occur suddenly in a minute or two. It is gradually intensifying over time and exerts impacts. Thus, drought is having a massive impact on agricultural activities that meet one of the basic human needs of food.

Drought in Sri Lanka

Under a changing and variable climate, the risk of drought is increasing worldwide, and Sri Lanka is no exception. Thus, Disaster Management Act No.13, 2005, of the

Government of Sri Lanka has identified drought and flood as 2 among the 21 natural or man-made disasters observed in the island (Ariyaratne, et.al, 2013).

Due to a combination of political, geographic, and social factors, Sri Lanka is recognized as vulnerable to climate change impacts, which is ranked 100th out of 181 countries in the world (source from Notre Dame Global Adaptation Initiative Country Index (ND-GAIN Index), 2017). There are two primary types of droughts that may affect Sri Lanka. These are:

- Meteorological – usually associated with a precipitation deficit.
- Hydrological – usually associated with a deficit in surface and subsurface water flow, potentially originating in the region's wider river basins.

At present, Sri Lanka faces an annual probability of severe meteorological drought of around 4%, as defined by the Standardized Precipitation Evaporation Index (SPEI) of less than -2. One study suggested that between 2001 and 2013, approximately 10% of Sri Lanka's population was exposed to drought (Amarnath et al., 2007). More than 122 people in 6 districts of Sri Lanka will be affected by the drought by 2020. According to the Government of Sri Lanka, the population is around 88,500 affected by drought this year. In addition, more than 90,000 people were severely affected by the drought in the same year, according to the Disaster Management Centre (DMC).

In addition, up to 1.2 million Sri Lankans have been affected by drought between 2016 and 2017, and 19 out of 25 districts have been registered as drought districts. In the North, North Central, and Eastern Provinces, the effects of drought have been recorded such as water scarcity, lack of water for agriculture, and drinking water problems. The impact of harvest and yield due to drought in 2017 led to livelihoods of the people, especially food shortages. Flood conditions are a problem on the one hand, and drought on the other hand has a huge impact on the daily activities of the people. Drought and floods are having a huge impact on the Sri Lankan community due to the untimely availability of annual rainfall to Sri Lanka due to climate change.

Women living in rural areas are still largely responsible for securing food, water and energy for daily use. With frequent droughts especially in the dry zone areas of Sri Lanka, women need to travel great distances to access clean water sources, this adds an extra burden to their already busy schedules, and gives them very little time to earn an income, get an education or for leisure. It is difficult for women to recover from a natural disaster as they do not own land or other liquid assets that can be sold to secure income in an emergency. In terms of climate change, women can play a pivotal role in helping to mitigate the effects of climate change, by giving them the opportunity to participate as role models, decision-makers, and as environmental stewards (Peiris, 2010).

Since Sri Lanka has been categorized as one of the top 10 countries for climate vulnerability, there is an increased need to make a climate-resilient economy. Sri Lanka is particularly vulnerable to climate-related natural disasters such as floods and droughts, which affect the poor disproportionately. The agricultural sector which

contributes approximately 7.7% to the country's economy and employs 27% of the population (more than 38% of women) are significantly affected.

The National Aquatic Resources Research and Development Agency (NARA) reports that the salinity of the Nandi Sea is increasing due to the ongoing drought in the Mullaitivu district of Sri Lanka and that many fish species are dying due to declining oxygen levels in the water. Most of the drought victims are people living below the poverty line, which is compounded by the fact that a majority of people in Sri Lanka depend on agriculture, which is often affected by drought (Climate Change Vulnerability Data Book, 2011).

Drought in the northwestern and southeastern parts of the country occur due to the failure of the monsoon in Sri Lanka. In some areas, the most severe drought occurs every 3 to 4 years, which has a lasting impact on the livelihood of people at large as the persistent drought lasts for several years. The most severe drought affecting nationally occurs once every 10 years.

Floods in Sri Lanka

Considering Sri Lanka's flood reporting, they focus on rivers. Excessive rainfall is the cause of the floods. Also, factors such as irregularity of drainage systems and irregular irrigation can be mentioned. The western and southwestern parts of Sri Lanka recorded the heaviest rainfall in May 2021 due to the southwestern monsoon. It was found to be 336 mm in the Central Province of Sri Lanka (Sri Lanka Meteorological Department). Many districts were affected by floods due to heavy rains with high winds. Of these, Galle, Gampaha, and Colombo were the worst affected, with displacements and property losses.

Extreme levels of flood disasters were announced in at least two places in Sri Lanka in 2021. Similarly, 43,701 people have been affected by the floods in 9 districts of Sri Lanka, of which 5 died. A 331 mm rainfall was recorded in the Kalutara district, leaving 15 dead and 2 missing in the floods. This has caused immense income resource crunch for the families.

The risk of flooding also rises as rainfall increases. Landslide floods in central provincial districts like Nuwara Eliya and Ratnapura are having a huge impact on people and their lives. It affects income sources and has a greater impact on vulnerable people. The Disaster Management Centre (DMC) reports that the floods of 2021 and the period of COVID-19 are making people more and more vulnerable and helpless. In addition, one person died, and another was injured in a flood in the Kandy district. In addition, 2113 people were affected in Kandy and Nuwara Eliya districts, and 122 houses were affected within 24 hours.

About 90% of the flood-affected people have returned to their homes, but 98% of the houses are still unrepainted and partially damaged. People are living in those houses, and they are doing the work of renovating their houses. Extreme weather and strong winds were recorded in the Western, Sabaragamuwa, and Southern Provinces, killing at least 4 people and injuring over 900. More than 200 houses and 6 buildings

were damaged or destroyed. These are matters registered by the Disaster Management Centre, Sri Lanka, in 2021.

Of the two types of disasters mentioned above, environmental journalism is the one that reports the most about the aftermath of the disaster. Climate and weather news have a special place in Sri Lankan radio and television news. In that sense, it is possible that people can have access to information about the impending disasters on a daily basis. However, it is questionable to what extent people are aware of prioritizing these. In that sense, it is safe to say that Sri Lanka's reporting has largely been of precautionary nature. Lack of modern technological facilities and personnel to implement them in Sri Lanka, a developing country, is a matter of concern as they do not reach out to people for timely caution, despite the fact that environmental journalism contributes to reducing the risks during disasters.

Identifying Misconceptualizations and Gaps

Discussion on disaster, risk, and media relations has a long history, and people themselves have interconnected the disaster-related communication to ensure community's safety from the catastrophic events. The news media narrative is one that people are acquainted with, and it conforms to bigger "formula storylines" (McKinzie, 2017: 04). McKinzie (2017) describes these formulaic stories as "deconstruction narratives" and sums up a few major themes of the evaluation of the said news. These include the immediacy of coverage, hero stories, religion, resilience, and solidarity. Most of the media networks in the Sri Lankan context have also presented the aforementioned characteristics of disastrous events, which are not entirely negative. However, it could be said that the competition created among journalists/media channels makes them prioritize their fiscal objectives rather than ensure the community's safety in a disaster event.

According to Goldberg (2002), news media employs "fantasies of homogenization" when representing post-disaster context. It means the media propaganda is demolishing the social aspect of the disaster and the media seems to focus on the harmful and hazardous elements. This emphasizes the nature of using media channels that use virtual platforms to increase their views instead of implementing proper mechanisms to mitigate the adverse impacts of the disaster event. Goldberg's term of fantasies of homogenization further shows how media networks generalize the effects of a disaster to the entire community despite considering ethnic, cultural, or gender differences, which differently experience the impacts of the disaster. When media networks and journalists working on disaster reporting can define what a disaster is and what is not, the improper engagement in terms of disaster management increases the complexities of the said contexts. Consequently, this further interrogates whether these environmental journalists are reporting ecological and social issues with their real, catastrophic nature or fantasizing/exaggerating the said events that could misinterpret the situation. This could lead to harmful consequences for both environment and community under the disaster risk.

Ethical reporting of a disaster event is a one major responsibility of an environmental journalist to ensure the psycho-social well-being of the victimized community. Even though being objective is an essential part of reporting news, it is not uncommon to find emotionally driven news stories and content that could emotionally harm. Environmental journalists need to be honest and at the same time ethical in their reporting of disasters. If caution is not practiced, it could lead to penalizing and harming the victims to a certain extent. As Milka and Warfield (2017) emphasize when disaster events have huge human costs, journalists frequently report live from the scene, interviewing recent victims of traumatic events, and news programs frequently show “distressing” videos or images. They further show how it influences ethical violations of the victims and question the role of media in disaster reporting. In the Sri Lankan context, this is not varied as reporting of the catastrophic event has become commercialized. The aforementioned disaster events were highly visible in the Sri Lankan context in recent history, and it was reported that many of the incidents were highly insensitive and unethically reported to grab the audience’s attention.

One of the main trends visible in the Sri Lankan context has been the “breaking news culture” which reported a number of deaths and physical harm with live videos from the said contexts. The most recent example is from the Aranayake landslide in Kegalle district, Sri Lanka, and the human losses and victims were lively telecasted on every local channel without any non-disclosure based on ethical concerns. Quoting these types of issues in many countries, Milka and Warfield (2017) exaggerate that “the people who unwittingly become news subjects, can often struggle with collateral damage as a result of hasty or incomplete reporting.” Hence, advocating the reporting of trauma during disasters needs proper attention, to focus on ethical security that every environmental journalist should ensure.

According to Abeywardhana (2018), disaster events are becoming a mode of maintaining images of politicians. In other words, disaster contexts are filled with power and political mediations. Furthermore, “the involvement of political leaders in disaster communication is problematic from the perspective of emergency agencies” (McLean & Ewart, 2015). This is further proven by the quote from Olson (2000: 265) that the “politicization of the disaster increases as the impacted community, or at times an entire society, moves from emergency response through to the recovery and reconstruction phases.” These scholars emphasize the influences of political mediations in destructing disaster contexts. In that sense, political influences may affect delivering distortion of information to the community which reduces the mitigative measures of the community. When government public official fails to grasp the dynamic nature of public expectations in the pre-disaster context, they may not be able to facilitate the public in overcoming disaster risk. That obviously will keep them in peril of the forthcoming disaster.

Even though political mediations can also be positively used in managing post-disaster context, most of the power groups that activate in the disaster context function as target-oriented groups instead of being supportive mechanisms to the affected communities so far. Simply put, the disaster context became the mode of manipulating the community for political purposes in many instances in the local

context. For that purpose, political parties use media networks that are more influential to the community than all sorts of communicative channels. Consequently, the duty matters to the media are subordinated to those political priorities, and it marks certain drawbacks in the role of environmental journalists.

In Sri Lanka, this is very much visible in flooding contexts which are much more prominent compared to other disasters. Flooding disaster is the second critical disaster according to the spatial distribution of disasters in Sri Lanka, and drought is in the first place; yet flooding creates spontaneous outcomes compared to drought, and the visible impact is higher when it comes to flooding disaster (Abeywardhana, 2020). Political parties are mediating the distribution of subsidies, and it creates a safe social environment for the community to a certain extent due to fulfilling people's basic needs. In contrast, their mediation in popularizing their image and use of media for that purpose is much visible in those contexts. Hence, media in such contexts overlook their real duty which means communicating risk information and contributing to how risk is perceived among communities with reliable information.

Furthermore, the media itself becomes a power group in the context of disaster. It assigns power to the environmental journalist in delivering essential information as it has a huge impact on the well-being of a disaster-prone society. The reason is that the risk communication can enable the preparedness of the community for the disaster which directly reduces the adverse effects of the disaster. The wide range of media channels is popular among people, and people themselves can obtain essential information that they are striving to be gained in an unpredictable disastrous event. Hence, the dimensions and variabilities of disaster communication networks, which are media channels, can function as a beneficial mechanism in overcoming disaster risk as well as increasing awareness of an ongoing disaster. Given the aforementioned information, media networks and their representatives who are the environmental journalists can contribute to monitoring disaster context and mediate in rebuilding after the disaster with reliable information and dominancy in disseminating information. Henceforth, the proper identification of their role and vindicating negative consequences of their misinterpreted role-related information could leave redundant impacts of disasters to a higher extent.

Conclusion and Implications

The best way to raise awareness among the community is through environmental journalism. It is the collection, verification, production, distribution, and display of information on current events, trends, and issues related to the inhuman world. To become an environmental journalist, one must have an understanding of scientific language.

Environmental journalism is focused on creating awareness in the community; creating discussion on environmental issues; promoting safety; providing coherence to topics ignored in the general media; creating collaborations among members of the public, communicators, institutions, NGOs, and any agent involved in

environmental issues; and promoting the approval and improvement of environmental policies.

Drought and floods in Sri Lanka are serious problems and natural disasters. The manner in which these are exposed by the environmental journalists, it is hoped, would help raise public awareness about impending disasters. At the same time, it may also lead people in becoming unnecessarily scared and nervous. Despite some negative effects, environmental journalism has been contributing positively in creating informed communities, besides helping achieve sustainable development goals to keep the environment clean and green.

Abstract

The Indian subcontinent with a long coastline of 8041 km experiences nearly about 10% of the world's tropical cyclones. Among the cyclones originated in the Bay of Bengal, more than 58% hit the east coast. Though on an average two to four tropical cyclones hit India every year, most of these cyclones impact the states of West Bengal, Odisha, Andhra Pradesh, and Tamil Nadu situated in the east coast. Due to frequent occurrence of cyclones, these states experience major casualties such as loss of life and properties and severe damage to infrastructure.

The super cyclonic storm *Amphan* made landfall in West Bengal on 20 May 2020 which caused widespread damage in West Bengal and Odisha states of India with loss of 128 human lives. The chapter assesses impact of these fatalities on surviving members of the families based on their original experience through qualitative research and reports of grief-focused journalism after the event. The study reveals that when the member of a family dies of natural hazards, it naturally leaves the survivors in distress on multiple fronts, viz., economic, social, and psychological. The chapter recommends workable measures for the survivors to secure their livelihood, food, nutrition, shelter, and physical and emotional well-being.

Keywords

Landfall · Fatalities · Traumatic stress · Livelihood insecurity

Introduction

There are many natural disasters like flood, cyclone, earthquake, landslides, etc. which have devastating effect on the human societies across the world. Tropical cyclone is one of such hazards that originates over oceans and progresses toward the coastal areas causing heavy damage to human lives, assets, infrastructure, and society at large. Coastal states of India are also regularly hit by tropical cyclones originated over the Bay of Bengal, Arabian Sea, and Indian Ocean. These cyclones regularly cause devastation to these states due to heavy rainfall and high-speed winds. Though all coastal states of India are affected by tropical cyclones, the east coast is more prone to such natural hazards than west coast. Tropical depression is considered to be the major contributing factor for the formation of cyclones in the eastern coast of India (Deccan Herald, 2020). Odisha, West Bengal, and Andhra Pradesh are the states situated in east coast of India that experience the devastating effects of tropical cyclones resulting in large number of losses of human lives with severe damage to public and private properties. The effects of these cyclones are not limited to human casualties and infrastructure. Due to rise in sea levels, seawater inundates to the low-lying areas of coastal states which causes widespread damage to crops and vegetation and erodes the beaches as well as embankments (IMD, GoI, 2021). During the post-landfall of cyclone, there are reports of spreading of communicable diseases (James et al., 2005).

The super cyclone of 1999 that hit east coast of Odisha state has been the strongest and most deadly recorded tropical cyclone experienced in any of the Indian state causing death of 9887 people with severe damage to properties amounting to US 4.44 billion dollars (Government of Odisha, 1999). BOB 03, Pyarr, Phailin, Hudhud, Fani, and Amphan are the other major cyclones that hit the states in east coast of India during the years 2002, 2005, 2013, 2014, 2019, and 2020, respectively (Telangana Today, 2021).

Cyclonic Storm Amphan Hits the States of East Coast of India

Amphan, a deadly tropical cyclone, hit the east coast on India on 20 May 2020. Cyclone Amphan had its landfall between Digha in West Bengal state of India and Hatiya Island of Bangladesh. After the landfall, the severe cyclonic storm acquired a sustained wind speed of 155–165 km per hour spiraling up to 185 km per hour. It then moved to north-northeast and further weakened to a cyclonic storm. On 21 May 2020, Amphan centered over Bangladesh, around 275 km from the city of Kolkata toward north-northeast (Deekshith Nevil Pinto, 2021).

The cyclone caused widespread damage to the states of West Bengal and Odisha in India and parts of Bangladesh. West Bengal being the epicenter of cyclone experienced most of the casualties. Nine districts including three coastal districts of West Bengal were affected due to the super cyclonic storm. Kolkata, East Medinipur, West Medinipur, South 24 Parganas, North 24 Parganas, Howrah, and Hooghly were the districts severely affected due to cyclone, while Murshidabad, Kolkata, and Burdwan were the districts partially affected (Fig. 1). High-speed winds were coincided with astronomical tides that ravaged Kolkata and other parts of West Bengal with uprooting of trees and electric posts, damage to thousands of houses, and swamping of low-lying areas. The powerful storm caused massive

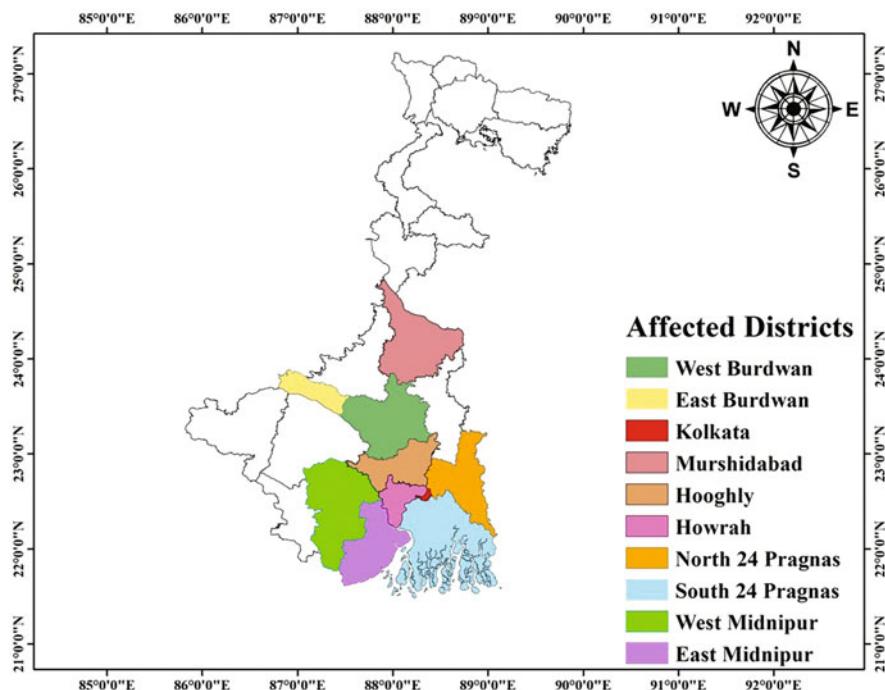

Fig. 1 Districts affected due to the cyclonic storm Amphan in West Bengal in 2020

damage to standing crops, livestock, water supply, and irrigation infrastructure. Eighty-six people reported to have died in West Bengal. The Government of West Bengal in its assessment had claimed that 21,650 km² of area were affected by the cyclone by impacting the lives of 28.56 lakh households comprising of 13.6 million people (UNICEF, 2020). The other major damages include loss of major crops in the affected areas including paddy, vegetables, and betel vines covering the gross cropped area of 17 lakh hectares; severe damage to 2.50 lakh hectares of orchards of betel vine, mango, and litchi; death of 21.22 lakh domestic animals; and loss of livelihood-supporting assets of fishing communities like boats, nets, etc. 61.80 lakh people were reported to have been evacuated and accommodated in 5136 relief camps such as multipurpose cyclone centers, schools, and other places (SIAG, 2020).

Odisha, the neighboring state of West Bengal, was also affected due to the cyclonic storm Amphan. Nine districts of Odisha, namely, Balasore, Bhadrak, Kendrapara, Jagatsinghpur, Mayurbhanj, Cuttack, Jajpur, Keonjhar, and Khordha, had been affected due to the impact of cyclone (Fig. 2). Balasore, Bhadrak, Kendrapara, and Jagatsinghpur are the four districts reported to have been severely affected due to the cyclone (NDTV, 2020).

Amphan had hit these districts of Odisha with wind speeds reaching 106 km per hour and rainfall up to 300 mm. 4.4 million people were reported to have been

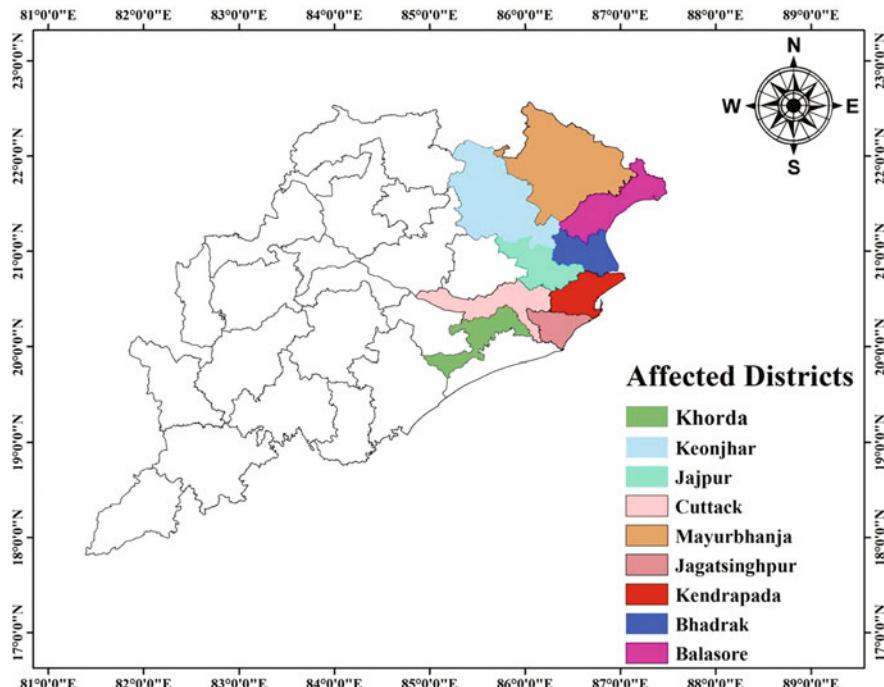

Fig. 2 Affected districts of Odisha due to Amphan cyclone in 2020

impacted in some or other way due to the cyclone with the death of four persons. There has been total collapse of 500 houses with damage to another 15,000 dwelling units. There were also casualties to more than 4000 livestock and primary poultries (Relief Web, 2021). Amphan has been regarded as the strongest ever tropical cyclone that hit east coast of India after the devastating super cyclone of Odisha, 1999 with economic loss amounting to 14 billion US dollar (International Federation of Red Cross and Red Crescent Societies, 2021).

Objective, Study Area, and Methodology of the Study

After the relief and restoration work of Amphan cyclone, a study was conducted after 6 months, i.e., during December 2020 to February 2021, to know the impact of deadly hazard on the surviving members of families of the deceased members. 321 surviving members of the 90 persons who lost their lives in the cyclonic storm have been contacted during the course of study in the affected areas of West Bengal and Odisha. The respondents were consulted through the help of a common assessment tool, focus group discussions, and individual interviews to ascertain the impact of these fatalities on surviving members of the families of deceased persons based on narration of their original experience. Twenty-four focus group discussions were organized by involving 245 respondents to know their responses on their experience after the demise of member of their family. 148 respondents were also consulted by the way of individual interview through a specially designed questionnaire. The respondents were assessed based on their participation in the discussion and vocal responses on identified parameters relating to post-disaster suffering. The focus group discussions and individual interviews were organized based on a set of checklists prepared on multiple fronts relating to insecurities caused due to loss of food, nutrition, livelihood, shelter, and emotional well-being. The questionnaire and checklists prepared were piloted in 2 focus group discussions and 15 individual interviews before its rolling out during the course of study. The field investigators and FGD observers were trained to moderate the discussions and note down relevant information by not being carried away by the emotions of respondents. FGDs and individual interviews were organized in the most affected districts of the states of West Bengal and Odisha. East Medinipur, West Medinipur, South 24 Parganas, North 24 Parganas, Howrah, and Hooghly were the districts of West Bengal where the field study was conducted. Bhadrak, Balasore, Kendrapara, and Jagatsinghpur were the cyclone-affected districts of Odisha where the study team conducted FGDs and individual interviews with the respondents. The primary stakeholders like widows, elderly persons, women, children, and disabled persons were contacted to know the extent of their sufferings as well as their coping mechanism after the disaster. Apart from primary stakeholders, other respondents like elected representatives of Panchayati Raj Institutions, teachers, informal leaders, and community-based institutions like Self Help Groups and youth clubs were also contacted to have a clear understanding of the situation. Apart from distress and destitution after the demise of a family member, the coping strategies of surviving members for running

their families and relieving post-traumatic stress were also analyzed as a part of empirical research.

Original Experiences on the Sufferings and Distress of the Survivors

Food, Nutrition, and Livelihood

The food security, nutrition, and livelihood of the surviving members of deceased members of families have been assessed as first phase during the course of study. As per the report of Joint Rapid Need Assessment Team published by the State Inter Agency Group comprising representatives of leading nongovernment organizations (NGOs) and officials of the Government of West Bengal on 12 June 2020, standing crops were destroyed in millions of hectare fields in the cyclone-affected areas of West Bengal. Especially the crops like ridge guard, bitter gourd, pointed gourd, okra, elephant foot, cauliflower, and other vegetables were heavily damaged on the point of being harvested. Other than crops, paddy fields, vegetable gardens, betel vineyards, fruits orchards, and traditional village crop store houses were also destroyed. Lemon orchards were severely damaged with uprooting of other fruit-bearing trees like mango, litchi, and jackfruit (SIAG, 2020). During interaction with the farmers, it was reported that since mango and litchi orchards were taken on lease, they had to bear huge economic loss which they had invested through lending from informal sectors. The entire farming community had to suffer as almost every vegetable field had been destroyed due to the cyclonic storm. The burden of repayment of loan further compounded the problem of farmers as they did not have enough money even to sustain basic needs of their families. Interaction was made with 321 respondents on impact of the cyclonic storm on their livelihood and nutrition security.

Source: Field Study

It can be seen from Fig. 3 that 24% of the respondents have opined that their livestock population and inland fisheries got severely damaged. On the front of availability of adequacy of food grain available with them beyond 1 month of the strike of Amphan cyclone, 52% of the respondents were of the opinion that they have insufficient stock of food grains to last beyond 1 month to sustain their families. Since most of the crops were damaged on the verge of harvest, they had to depend upon relief from other sources. Fourteen percent of the respondents reported that since their houses have been completely damaged, the places where they used to store food grains were also destroyed. They do not have enough food grain to run their family even for a week. It can further be seen from the table that 61% of the respondents reported to have inadequate nutrition intake after the landfall of Amphan cyclonic storm in their locality. It was revealed from the field study that children are the worst sufferers due to cyclone and they were not getting same amount of nutrition they used to eat resulting in the risk of malnutrition especially to

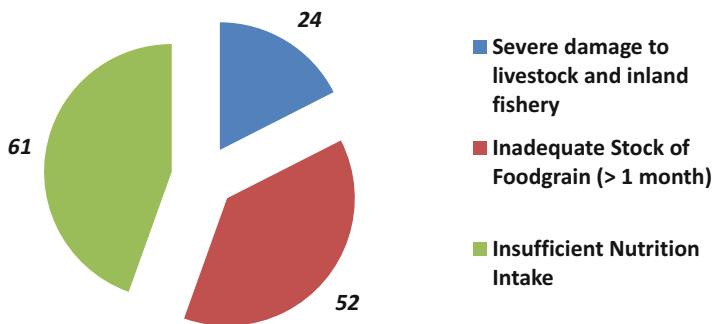

Fig. 3 Percentage of responses on impact on Livelihood and Nutrition due to cyclonic storm

the poor households. It was also reported that due to damage of Anganwadi centers and ongoing COVID-19 pandemic situation, instead of supplementary cooked food, dry rations were distributed. There were also responses of less than recommended food intake among the pregnant and lactating women increasing further the risk to them on the front of malnutrition. Since many people of the Amphan-affected districts lost their summer crops and livestock, it enhanced their vulnerability to low yield of monsoon crops. Hence food crisis was further intensified in the affected areas.

Loss of Shelter

It was revealed during the interaction with participants that dwelling units have been damaged due to the strike of cyclonic storm Amphan in the affected districts of West Bengal and Odisha.

Source: Field Study

Figure 4 indicates that 27% of the respondents reported that their dwelling units have been fully damaged, while 35% were of the opinion that those have been partially damaged due to the cyclone. Remaining 28% of the responses were that their houses were intact and not damaged due to the cyclonic storm. Hence the consequences of Amphan cyclonic storm left 62% of the surviving members of the family to live in damaged houses which were not suitable to live. Few of them were forced to live in the houses of other people of their village whose houses were not affected. Many of them had to live in constructing temporary shelters with the help of tarpaulins they received from government and nongovernment organizations. Since supply of electricity was not possible during the post-cyclone scenario in temporary shelters, this led their exposure to wild animals, snake bites, and mosquitoes. It was noticed during the interaction with the respondents that many of them did not have blankets, bedsheets, kitchen utensils, and other goods which were essential in their daily lives.

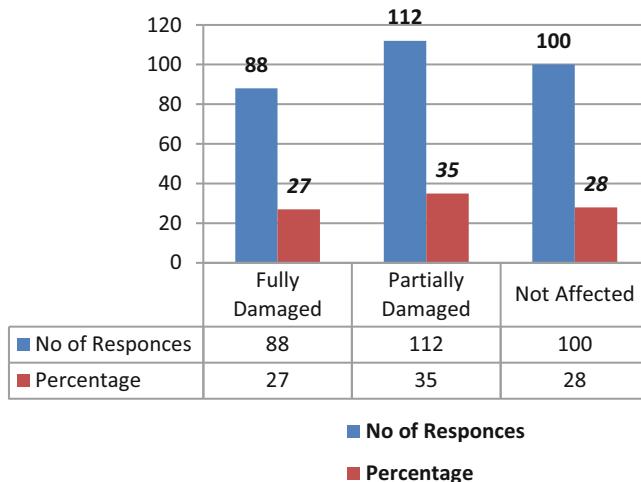

Fig. 4 Responses on damage to houses due to cyclonic storm *Amphan*

Dwelling units of people in East Medinipur, West Medinipur, South 24 Parganas, and North 24 Parganas districts of West Bengal were reported to have heavily damaged due to the cyclonic storm (SIAG, 2020).

Physical and Emotional Well-Being of the Affected People

The cyclonic storm Amphan resulted in the disruption of health system which made people to suffer without access to emergency healthcare services due to damage to basic infrastructure of primary healthcare units such as electricity and water supply after the disaster. The medical teams also could not reach to the remote and far-off places after the strike of cyclone.

Source: Field Study

Figure 5 captures the responses of surviving members of the families on the post-cyclone health services. It is clear from the table and figure that 80% of the respondents expressed that they had the experience of deficient health services due to inadequate availability of medicines, essential supplies, equipment, and staffs. Though healthcare providing personnel like doctors, nurses, and ASHA workers were available in the villages, outreach services in remote and inaccessible villages were not to the desired extent as opined by them. Removal of dead bodies was delayed, and the injured people were not also shifted timely to avail secondary and tertiary healthcare services. Respondents also reported to have suffered from water-borne diseases like diarrhea and hepatitis during the post-cyclone scenario in severely affected areas. Due to exposure of people to contaminated water and poor sanitation during and after the cyclonic storm, there were complaints of common

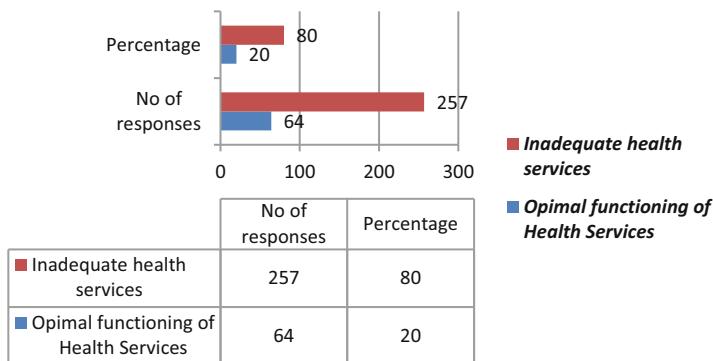

Fig. 5 Responses on the post-cyclone health services

cold, flu, throat infections, headaches, skin rashes, gastrointestinal illness, etc. which intensified further the suffering of survivors. The COVID-19 pandemic also further complicated the situation. It was difficult for the affected people to maintain physical distancing at cyclone shelters for which the numbers of coronavirus cases in the affected areas were also reported to have increased (SIAG, 2020).

Death of a member of family and other sufferings left the survivors in the state of deep shock. The post-disaster traumatic stress and loss of emotional equilibrium were clearly visible among the survivors which could not be quantified during the course of study. Damage to shelter and valuable assets, livelihood insecurity, and death of closed one made them to feel insecure and vulnerable to elevated level of psychological distress. Most of the survivors had symptoms like uncontrollable stress and feeling of grief and sadness for a prolonged period after the cyclonic storm. Other effects of psychological health such as disturbance in sleep, dependency on alcohol, and fear of socialization were also reported by the respondents during the course of interaction.

Grief-Focused Media Reports of Post-Amphan Scenario

A customized search engine was created in Google which was searched on the Amphan cyclone and its impact from 16 May 2020 to 16 August 2020. The sample consisted of five English e-newspapers, namely, *The Hindu*, *The Times of India*, *Hindustan Times*, *Indian Express*, and *The Telegraph*, and five news portals of Zee, ABP, Ei Samay, Orissapost.com, and Doordarshan, the national broadcaster. The data analysis is based on sentiment analysis of the content including media coverage on the issue in the duration specified. A critical observation on the media report reemphasizes the propaganda role of media. The content analysis of stories was done by three coders on five parameters classifying if the story had elements of nature's fury, human sentiment, governance aspects, financial measures, and civic amenities

like water supply, electricity, transport, and public health. The analysis revealed three types of coverage in accordance to the time phase. In the initial report, optimum use and graphic details of the speed, path, and route of destruction taken by the cyclone were emphasized. During the time that the cyclone hit, emotional explicit was used in the news stories with empathy, human sentiment, and loss aspects highlighted in news stories.

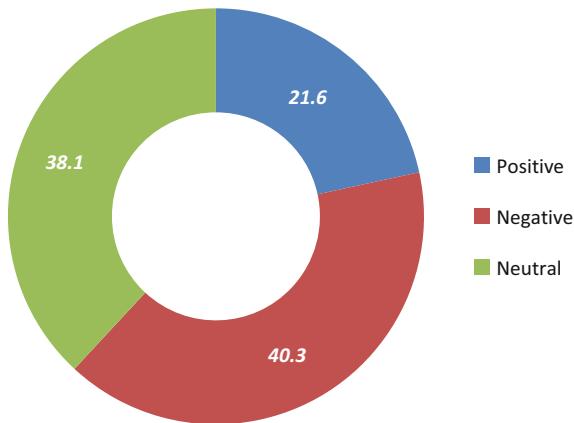

In the post-cyclone phase, to reflect the aftermath of the trail of destruction left behind, pictorial specifications of the destruction which in case of live coverage on portals and static pictures in e-news were particularly appalling were used blatantly. The media does not leave much to imagine as it glorifies the crisis and saga of destruction that the reports carried. *The Telegraph* in particular gave emphatic details of the deceased along with numbers of the office and location to reach for help. Stories ranged from the preparedness for the cyclone to the destruction during and post the cyclone and controversies regarding compensation given to families who were ineligible beneficiaries. Even celebrities found ways of making news related to the Amphan cyclone as they announced aid or dedicated songs to the crisis-ridden people of Bengal and Orissa. The thin balance between news and views gets fogged as one debates how the usage of vocabulary, words, and images can create a magnitude of emotions in the recipients.

It is true that media plays an important role in the disaster management. After a disaster, news media assists in quickly providing a narrative on how that particular incident has affected and impacted areas, thus helping authorities to more efficiently reach aid to survivors.

News media is also expected to provide an independent and authentic reportage from ground zero to people at large. This empirical study, however, suggests that media and disaster management authorities often have varying perspectives on the particular tragedy. It is also a fact that in an era of “breaking news,” media narrative at times lacks empathy and may border sensationalism. The digital space summarizes that during such events, the loud display of emotions desensitizes human sentiment rather than stir it. The thin balance and quality to put things subtly in perspective seems to have been overthrown completely by the bandwagon of breaking news and TRPs. As an average person makes a sense of the situation through the media stimuli, the text and images leave an imprint on the psyche of the people in general and survivors in particular, both in a positive and negative manner.

The sentiment analysis based on the media reports as depicted in Fig. 6 clearly shows that 40% of the media content is negative. This negativity is a summation of words having a negative connotation like storm, loss, damaged, etc. The error in automation does not allow Amphan cyclone as a name to be included in this list of negative, hence the text shows such words as neutral, whereas only 21% of the content is positive connoted by words like livestock, plants, etc., whereas these words were mainly used in sentences referring to loss. The range of stories particularly in print catered to a wider range of subjects including how failure of electricity had affected the diabetic patients’ life as insulin and other drugs need to be refrigerated at low temperatures and electric failures lasted for 3–4 days. Audio visual media concentrated more on the grief aftermath of destruction that the cyclone

Fig. 6 Sentiment Analysis based on reports of media

left behind, wailing individuals; battered streets, vehicle, and houses; floating belongings; and uprooted trees.

Conclusion and Recommendation

The cyclone Amphan of 2020 was one of the most powerful and deadly tropical cyclonic storms that occurred in the Bay of Bengal which caused massive damage to human life, properties, and infrastructure in the states of Odisha and West Bengal in India and neighboring country Bangladesh. In terms of human and material casualties, this is considered next to the super cyclone of Odisha that made landfall in Jagatsinghpur district of Odisha in the year 1999. The cyclone Amphan estimated to have caused 128 deaths, damage to properties and infrastructure to the tune of 27 billion US dollar and lives of 18 million people were affected in the states of Odisha and West Bengal taken together (SIAG, 2020).

The devastating effects of cyclones were not limited only to human casualties and infrastructure. The cyclone had caused widespread damage to crops, vegetation, livestock, fisheries, and houses in the affected areas and impacted the physical and emotional well-being of people. The study based on assessment in the affected areas and interaction with 321 surviving members of the families of deceased persons recommends the following.

(a) Food, Nutrition, and Livelihood Security

- I. Government of West Bengal and Odisha needs to provide agricultural and livelihood support to those who have lost their standing crops and productive assets during the cyclone.
- II. Since food security was the major concern of many affected households, local administration needs to ensure availability of proper quantity of culturally appropriate food with minimum nutritional requirement to

- cater to the need of all vulnerable sections of community in the affected areas such as children, pregnant women, lactating mothers, and sick and elderly people.
- III. During the pandemic period from April to November 2020, the Department of Food and Civil Supplies of the Government of India had allocated 680 Lakh Metric Tonne (LMT) food grains to the states and union territories under the Public Distribution System (PDS). About 350 LMT were allocated for distribution under normal National Food Security Act (NFSA), 2013, and Targeted Public Distribution System (TPDS). Additionally, about 321 LMT were allocated for free-of-cost distribution under Pradhan Mantri Garib Kalyan Anna Yojana (PM-GKAY) and 8 LMT under Atma Nirbhar Bharat Scheme (ANBS) (MoCA, F & PD, GoI, 2021). Under ANBS, the beneficiaries were allowed to seamlessly access entitled NFSA food grains anywhere in the country by using their same/existing ration card along with biometric/Aadhaar authentication on an electronic point of sale (ePoS) device at the fair price shop of choice. Hence, it is suggested that PDS distribution should be done on priority during the period of post-natural calamity under Antyodaya scheme which entitles 35 kg per person for 6 months. The households of the affected areas should access its benefit on the basis of iris scan which is widely recognized as automated method of biometric identification as all people in villages may not have clear fingerprint impressions. Moreover, people who have undergone the trauma of losing house and all belongings might not have their ration card/Aadhaar card to produce during the period of crisis. This will ensure security and survival of the people affected with multiple shocks.
- IV. Government should provide unconditional cash transfer support for the most affected families after returning home from the relief camps to meet their immediate priorities. Affected households may be provided with cash to start the activities like farming, construction of houses, cleaning of ponds, repair of fishing boat and net, etc.
- V. Short-term emergency farming activities like distribution of seeds, live-stock, agricultural input, and tools may be provided to the affected farmers in order to protect their livelihood. Special assistance may be given to the farmers for betel vine production. Targeted livelihood support may also be extended for the marginalized households.
- VI. As a part of long-term preparedness measure, community-based seed preservation needs to be encouraged at village level by involving Self Help Groups and farmers group in order to achieve self-sufficiency in seed production. Genetic diversity may be promoted through exchange of seeds between different groups. The groups may be oriented to produce the crops as per local agroclimatic condition and need of the market.
- VII. Fruit-bearing plants need to be promoted in coastal areas having the capacity to withstand cyclonic storms. Organic farming may be promoted through natural application of bio-manure like compost, azolla, spraying

of cow urine, and cow dung to protect their crops from natural hazards like drought and flood.

- VIII. Dewatering of ponds inundated due to saline water intrusion and cleaning of fish water ponds at village level may be taken up in the affected villages. Complete cycles from egg to spawn, fry, and fingerlings for internal circulation in the affected areas may be encouraged.

(b) **Housing and Shelter Needs**

- I. Governments of the Amphan-affected states, i.e., West Bengal and Odisha, need to provide immediate support to the affected communities with essential items like tarpaulin, ground sheet, bedsheets, blankets, mosquito nets, ground mats, solar lights, ropes, etc. to deal with the crisis arisen due to damage of their dwelling units. The respective state governments also need to ensure shifting of affected communities to the transitional shelters.
- II. The affected communities who lost their houses during the cyclone may be provided with proper financial and construction support to reconstruct their houses with appropriate designs by utilizing local materials and human resources available locally. The capacities of local people and skilled workers may be developed to cater to the reconstruction requirement of people during the post-disaster scenario. Houses may be built through self-help-built approach through which affected household can rebuild their own houses at relatively lesser cost.
- III. There should be complete rehabilitation strategy for the people whose houses have been collapsed completely. Support may be extended to the affected households by providing package of materials, tools, and grant for construction of a durable house or repairing the damaged one.
- IV. The local craftsmen should be provided with revolving fund to purchase necessary toolkits required for construction of houses. Interface arrangements may be made in market places or fairs where the house owners can interact with the skilled craftsmen for undertaking the repairs at the earliest. Rural and urban local bodies may facilitate the initiative under the direct supervision of civil engineers available with them.
- V. All the existing mud houses in the affected areas should be converted to brick houses having toilets with concrete roofs. Households and craftsmen of the cyclone-prone areas may be trained with the skill to construct model low-cost cyclone-resistant houses so that people can adopt appropriate technology to retrofit and rebuild their house to withstand such natural hazards.
- VI. Local administration of both the states may take steps to decongest the settlements in villages with adequate space between the adjacent dwelling units. This may help in controlling the speed of communicable disease during the outbreak of epidemics like COVID-19 and others.

(c) **Health and Emotional Well-Being of Affected People**

- I. Due to spread of communicable diseases and other health hazards in the post-cyclone scenario, respective state governments need to temporarily

- depute healthcare professionals from other unaffected districts to participate in the medical outreach camps.
- II. Routine immunization services may be commenced immediately after the post-cyclone scenario in the affected areas. Immunization, antenatal, and postnatal services may be immediately restored in the waterlogged areas prone to spread of communicable diseases. All pregnant women need to be provided with necessary antenatal care on priority basis.
 - III. Information, education, and communication (IEC) materials on personal hygiene and sanitation prepared by public departments need to be distributed in the affected areas since people of these areas need to have basic understanding on personal hygiene to prevent the spread of communicable diseases.
 - IV. Due to overcrowding in cyclone centers and relief camps, menstrual hygiene of women is often overlooked which puts women and adolescent girls at greater risk. Local administration needs to ensure free distribution of sanitary napkins and clean towels and easy access to privacy and sanitation through separate toilets for female population.
 - V. Since waterlogging is the major contributing factor for sudden increase in mosquito breeding and outbreaks of vector-borne diseases like malaria, dengue, etc. in the affected areas, rural local bodies like Gram Panchayat and health departments need to ensure applying larvicides to control the same.
 - VI. Local administration of the flood- and cyclone-prone areas needs to map their available health infrastructure, personnel, and services. Based on their assessment, preparedness measures need to be strengthened through constitution of medical teams, safe storage of essential medicines, and preservation of cold chain system to control the health hazards during post-disaster scenario.
 - VII. Since grief and shock are the normal in the aftermath of natural disasters due to loss of life, shelter, and livelihood which has long-term impact on mental health, counseling and other mental health services must be extended to the affected people to cope with the situation and come back to the normalcy.

Finally, governments of both the states need to ensure proper coordination among all related departments of development administration to deal with cross-sectoral issues like providing hazard-proof houses, roads, culverts, etc., securing livelihood of the affected people, maintaining safe hygiene, sanitation, and food and nutrition requirements.

Abstract

For many years now, corporate organizations and the brands they own have been carrying out community outreach during floods in India. They employ various strategies and tactics of branding and social responsibility in their involvement in the flood management cycle. Their outreach efforts got recognized during the Kerala floods, thereafter consolidating their role in disaster ecosystem. Interviews with different persons involved in flood management, disaster research, mitigation, media, and corporate communication explained higher outreach marketing by companies using their products and use of social media during floods. Analysis of the outreach in each phase of the flood management cycle brought forth its asymmetrical nature reflected in more inclination toward relief and response phase. A three-pillar outreach model for corporate organizations has been developed based on empirical insights.

Introduction

The World Meteorological Organization (WMO) Atlas (2021) shows that 44% of disasters have been associated with floods (riverine floods 24%, general floods 14%) making it the most challenging disaster to impact human life. A research study by the Asian Development Bank (Patankar, 2019) concluded that floods constitute more than half of climate-related disasters in India that are frequent and deadly. The International Disaster Database, EM-DAT (2018) states that close to 750 million people have been affected by 278 floods in India between 1980 and 2017. Flood vulnerability in India is not limited to certain parts; in fact, it cuts across the geographical divide since it receives rainfall for 4 months (June–September) in most states. Low-lying rural areas have always been vulnerable, but of late urban floods too have become frequent. Therefore, subsequent governments have been adopting flood management approaches with increased outlays in the 5-year plans. NITI Aayog in its Report of the Committee Constituted for Formulation of Strategy for Flood Management Works in Entire Country and River Management Activities and Works Related to Border Areas (2021–26) noted that the Flood Management Programme (FMP) and the River Management Activities and Works related to Border Areas (RMBA) with approx. 18,000 crores to provide financial assistance to states and union territories battling with floods were merged as Flood Management and Border Areas Programme (FMBAP) for the year 2017–2020. Clearly, managing floods is not a standalone activity as it affects the community as a whole and requires efforts by different stakeholders, including the local administration, governments (state and central), first responders like the IAF and the Indian army, specialized agencies like the National Disaster Management Authority (NDMA) and National Disaster Response Force (NDRF), NGOs, private and business organizations, media, academic community, volunteer groups, social networks, etc. (Shree & Sagar, 2016). In the context of floods, community is a composite term. While it is a geographically identified group decided by the government or the industry (Adamson, 2010), and it means humans or families with same membership, influence, integration, and fulfilment of needs and shared emotional connection (McMillan & Chavis, 1986), in relation to corporate organizations, community is also a stakeholder on which an organization relies for its goals (Cook, 2015). On the other hand, outreach is invariably used together with corporate social responsibility as an extended rib. Distinctively, outreach here would mean direct involvement by brands or corporate organizations through activities that aim to resolve their social, economic, and cultural problems that arise due to floods. Hence, community outreach by brands has been operationalized as various non-profit activities undertaken by a

brand keeping a specific geographic cluster especially in relation to causes and impacts of floods affecting them during their lives.

People and Floods

When waterborne disasters strike, civil administration is the first responder. They contact the military and the specialized agencies like NDRF to start the evacuation of citizens, flood control, and construction of bridges in order to minimize the loss of life and materials. The local administration focuses on people caught up in the floods to provide relief and aid of various kinds. So, the initial goals of managing a disaster like floods are tackled by the government machinery, military, and paramilitary agencies. At the time, communities and the people around the world are increasingly dependent on media for news and contact (Ball-Rokeach & DeFleur, 1976). Media reports, information bulletins, and analysis via other modes of communication become their sanctuary. Social sector organizations commonly called the non-governmental organizations (NGOs) get into action next as they may be already working with the community. Close on the heels are private or corporate organizations identified as brands in the outside consumer world, moving in just as the emergency rescue operations by the army come to an end. They might not be the first to reach, but their outreach gathers attention of the media and the government bodies alike. Since flood-affected areas require massive attention and long-term facilitation at all levels, discussing the potential of brand outreach or community outreach by the corporate organizations, often interchangeably used, can contribute significantly in helping the locals in rehabilitation, finding recourse and build capacities toward the new normal in their lives. Conceptually, the author draws on Luhmann's (2012) Social Systems Theory (SST) which delineates various subsystems, i.e., organizations, interactive systems, and function systems like polity and media in communication of society as a whole. It is most suited as it conceptualizes a modern world society ideal for exploring the social relations among global and localized institutions, organizations, and networks (Stichweh, 2007).

Methodology

In order to determine the role of corporate organizations in community outreach during floods, interviews were held by the author with two disaster management researchers, five corporate communication/public relations officers, two NGO representatives working on flood-affected communities, and two journalists who covered floods in Kerala. Additionally, media articles and tweets on Kerala and West Bengal floods were studied. Themes from the empirical analyses converge toward increasing outreach by private companies or the corporate sector since 2014. But they differ on how brands understand communities and develop outreach programs. While most believed that corporates have attempted to reach out to the flood-affected communities in different ways, disaster researchers and NGOs believe that

companies need to go beyond the surface of contributing at the time of calamity and get involved in the communities they aim to befriend. NGOs found lack of sincerity in corporate efforts, making outreach a mere demonstration of social responsibility and nothing deeper. However, while covering the flood-affected areas in Kerala, Journalist Shruti Mohan found the efforts of brands by global and local companies more significant and stated that they were willing and sharp in their flood response activities (Interview Feb, 2022). The overall sentiment to brand outreach was positive about their presence at the time, but the quality of their outreach raised questions on their capability and competence. As Dr. Anil Gupta, Professor of the National Institute of Disaster Management (NIDM) says, “Since brands are looking to build reputation, it is important to be an informed participant in the process of flood risk reduction and resilience building right from the word go and not join in just for media mileage as reputations are a sum total of presence and performance” (Interview March, 2022). To identify specific outreach strategies adopted, analysis of empirical responses was done as under:

Outreach Strategies Adopted

I Brand Presence and Inventory Association Frame Outreach by Corporates

Because of media focus and emphasis on social audit, corporate organization's involvement in times of natural crisis especially natural calamity has significantly risen. Organizations across spectrum are actively involved and engaged in outreach during natural calamities, now more than ever before. Ali and George (2021) in their case study on *Community Resilience on Kerala Floods* 2018 found that corporates or private organizations like Joyalukkas and Muthoot Group were actively involved in community relief and resilience besides NDRF, government and NGOs, and celebrities among stakeholders. The weightage of community involvement which was actively driven by corporates and NGOs (especially local) and social media influence contributed 30% toward urban resilience of Kerala in 2018 (Ali & George, 2021 p.124). It became the defining feature of Kerala's demonstration of effective flood management. During the interview, Bhaskar Majumdar, Head of Corporate Affairs and Corporate Communication, Egis, replied that 'for all major brands CSR is a continuing commitment by businesses to integrate social and environmental concerns in their business operations' underlining that the seriousness around CSR regulations and community outreach has started to dominate the implementation of CSR for floods (Interview January, 2022). In the last decade, outreach by brands during flood has found acknowledgment from both the disaster specialists and the communication experts; Mr. Nakul Kumar Tarun, Director of Zone4Solutions and Secretary General of Public Relations Society of India and Editor PR Voice Babji Yana expressed similar views:

Recalling his experience of a flood in Jammu and Kashmir, Nakul shared that during the 2014 J&K floods it was noted that lots of private companies came forward

and supplied medicines to medical camps established by his organization, Tehse corporate even provided drinking water bottles, dry milk for kids and sanitary napkins, continuously for 27 days by commercial flights from Delhi every morning. “Private companies,” he said, “are technically very sound and cash reached so, they can (sic) become interface between community and government and contribute in data driven risk reduction policy decision making. Specially flood which is a recurring hazard in India. Corporate houses can implement effective post disaster need assessment for better planning in future” (Interview March, 2022), whereas Babji Yana responded that “Flood is a natural disaster and a crisis. Disaster relief operations are counted as CSR activities. When in floods, apart from governmental exercises, NGO’s, corporate organisations extend their help to the people affected” (Interview April, 2022).

In the interviews, other case studies of flood in states like Assam, Uttarakhand, Chennai, and Andhra Pradesh were mentioned helping us recognize that outreach may be more recent but corporate involvement in flood-affected communities has been there for several decades. Recounting outreach initiatives by brands, Babji Yana recalls that “In 2016, when Hyderabad experienced heavy rains, the area called Kukatpally, the north-west part of the City, where I live was inundated in waist-deep waters for 3 days. Organisations and Individuals came up with relief assistance like food pockets, milk, water and medicines till waters were diverted/receded. I saw Political Parties, Religious Groups, Business Houses, Industrial Establishments and even Movie Artists Association involved in this activity. Of course, governmental exercise can’t be compared, but corporates too were actively responsive” (Interview, April 2022). In the last 4 years since Kerala floods in 2018, brands are more aggressively doing outreach. With special reference to Kerala in 2018 and West Bengal in 2020, Majumdar pointed out that “Multiple brands have been involved during flood relief activities. Starting from medical assistance, rescue and relief work, food supply, rebuilding the infrastructure and many more,” in many ways making these two cases as milestones in brand presence and association.

Media analysis of Kerala floods shows active outreach by a large number of brands from different product categories like telecommunication, mobile applications, e-commerce, food delivery apps, etc. In a report, Navanwita Bora Sachdev (2018) informed that social media companies, e-commerce and e-wallets, telecommunication service providers, online grocery, and some local IT companies were making donations and providing connectivity, traffic-related information, and food supplies to the community. In an article, Saumya Tiwari (2018) writes that e-commerce chains were collaborating with local NGOs for flood response in delivering relief kits and essentials. Despite numerous examples, qualitatively, the outreach strategies are inadequate. To begin with, there is lack of outreach for flood adaptation measures. Both the disaster scholars and communication professionals believe that outreach strategies are not inclined toward adaptation. Measures like proactive support (infrastructural) during evacuation and relocation of the flood-affected community are not included. Largely, the brands walk on the heels of the government as a contributor but not a cooperative partner as envisaged in the public-private model for welfare and social change in India. Most of them felt that limited outreach

is being done by the corporate organization to build flood resilience. Director of Value Education Trust, Annie Samuel, who was directly involved with the community during Kerala floods feels that several projects are launched as they get photo opportunities and newspaper coverage and corporate organizations do outreach in order to complete their CSR reports. Once the sensation is gone and they will no longer be in news, brands stop shop. What is required instead is a brand to adopt a community, e.g., children from fifth to tenth grade flood-hit region in Kerala, and build education infrastructure and economic support to improve their skills and ensure continuity in their education (Interview Feb, 2022). Annie Samuel says that “unless community is empowered none of the agencies can help. Empowerment programme is the need of the hour.”

II Donations maximise Outreach, and Inventory forms the core of relief

Conventional mode of philanthropy of giving money remains the most adopted strategy by brands. Donation drive by an e-wallet company raised more than ₹ 35 crore, while a leading consumer goods company donated sachets of its own product, water purifier, in their outreach program on safe drinking water for children during Kerala floods in 2018 (Tiwari, 2018). Media reports suggest that CSR, sustainability and community outreach arm of leading business organizations have been contributing to the PM/CM relief fund as outreach or corporate social responsibility during the floods (December 6, 2018). Tiwari (2018) in her article mentions that a Mumbai-based corporate also donated to the CM disaster relief fund in addition to donating brand-based inventory like purifiers and hand sanitizers. Flood-affected community needs mammoth financial resources; hence, they welcome donations. Parallel to it, governments require funding to control, communicate, and construct disaster support systems which is why donations to the PM relief funds are made tax-free. Brands, in return, earn the approval of both the local community and the party in power for future projects with not much community involvement. However, in some cases, as Shruti Mohan points out, “donations are not merely stimulated by financial exemptions but are a part of network building exercise for an organisation that wants to enter into a community and sustain itself in proximity.” Alternatively, outreach marketing is also common. Relief items that are part of brand inventory such as baby food, sachets of milk powder, and toiletries either are donated or are distributed onsite at subsidized rates (Fig. 1). Pravin Francis, a Corporate Sales Officer for a mattresses brand, on his social media handle wrote: XYZ (name changed) mattresses of Kerala provided 50% off on their mattresses for flood victims in 2018. While others were skeptical of brands using floods to introduce their products and converting the affected community into target market, Bhaskar Majumdar contends that any contribution during disaster time, particularly floods, is helpful to the cause. Many organizations may not have the bandwidth internally to provide all the required help and support during any natural

OUTREACH

Fig. 1 An illustration of brand inventory forming outreach strategy. (Source: Jasdeep Kaur Chandi, Ph.D. scholar, USMC, GGSIPU)

calamity, but their monetary contribution can always be useful. Lots of time, brands also help and support using their existing inventory. Motor vehicle companies can offer their vehicles to be used as ambulances or for relief work, network operators can create specific helplines and other offers for the affected areas, finance companies can offer their customized services, healthcare organizations can offer their expertise, etc. (Interview March 2022). Objectively for a brand, outreach marketing using the existing inventory is much easier to provide help and support on a real-time basis, and therefore it will remain a potent tool as it combines profit motive with non-profit goals.

III Digitally Enabled Outreach

Communication is vital during disasters. Floods in the two states also showed emerging forms of outreach communication that used digital technologies to combine on-ground activities with communication networks on the social networking sites. Yadav and Rehman (2016) in their case study of Chennai floods found productive use of social media particularly in disaster resilience. Several hashtags on Facebook and Twitter like #Chennairainshelp @chennairains saw information

being shared on flood situation and rescue by people all over using Google Missing Person Finder, Facebook Safety Check, and Google Crisis Response page. Largely, social media usage during disasters is not just limited to crowdsourcing and sharing emotions but also arriving at curative initiatives (p.100) where brands can be a potent force. This kind of community outreach applies the continuum of e-mobilizations, e-tactics, and e-movements as stated in Earl and Kimport's (2013) digitally enabled social change. Recent floods saw various stakeholders maximizing the use of social media to amplify call for action, spatial information of the disaster, and relief measures besides continuous updates on the floods similar to the emergence of social media for dissemination of information through Facebook during 2011 floods in Australia (Bird et al., 2012). How social media has enabled community outreach is evident from the extensive use of shared media during the Kerala floods and later in Assam and Tamil Nadu.

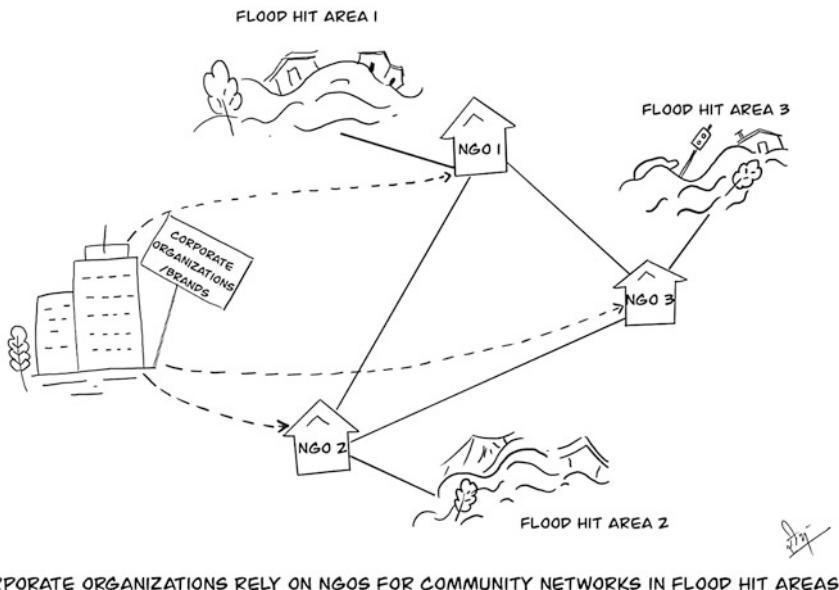

Role and Scope (Brands, Outreach, and Flood Management Cycle)

Corporate involvement in the flood management cycle (Thieken et al., 2007) is critical to understanding the scope of outreach. At the first stage pertaining to *prevention and mitigation*, corporate outreach seems like an oxymoron. Brands' insouciance in general during the prevention stage has been noted by the government, non-governmental organizations and regulatory authorities. It brings to fore the uncomfortable interrelationship between on-site industrial development and social consciousness. With neoliberalization, multi-stakeholder projects have established the corporate footprint across the length and breadth of the country. As a consequence, likelihood of several natural and manmade disasters especially floods has increased. Dr. Anil Gupta, Professor at the National Institute of Disaster Management of India, explains that the risk of floods looms large when water's natural course comes in conflict with the physical development activities or when communities are habiting the low-lying areas. Rural areas are especially vulnerable because the carrying capacity of water bodies like rivers has come down due to industrial mining. It results in siltation, causing flooding at regular intervals. Since large corporate organizations are undertaking the developmental works including highways in these areas, they are often found guilty of making the place and people susceptible to the onslaught of floods (Interview Feb-March, 2022). At the preventive stage, corporate involvement must draw from the "responsible care" paradigm which professes ethical business practices which come with social and environmental accountability so that their minimum harm to the community is done where installations are at work. He further explains that "adopting a proactive approach to community means providing proper green cover and not slashing through the water bodies, and that will create a loop of care between the corporate and the community. Between the two, most workable is the notion of responsible care that existed right in the beginning." Outreach is when industrial companies in the area adopt transparency in conduct instead of relying on the age-old practice of "extra-commercial activities" (business philanthropy) to

redistribute part of their wealth as relief funds for affected communities (Krichewsky, 2019). The biggest outreach vacuum was found at the *preparedness* stage. Low or weak participation of corporate organizations during preparedness is one of the biggest concerns raised by many during empirical data gathering. Those interviewed expressed that brands are invisible during disaster preparedness and scantily contribute to collaboration with the government on advance planning to map community needs and prepare disaster response kits. No such community mapping initiatives were found to bolster preparedness against floods. Some companies in general continue to engage in research on disaster-prone communities but as such flood community mapping or audits were not seen. Babji Yana underlined the role of companies in preparedness in the interview stressing upon that “the effective way of Brands / Organisations in flood management could be, to help clearing flood waters during floods and maintaining waterbodies, de-weeding of lakes, de-clogging of drains etc. by providing machinery and equipment to local Government in their pre and post monsoon operations.” Nakul Kumar Tarun presents the profitability of preparedness when he says that “mere donation cannot help. They need to enhance their own knowledge base to get involved in each phase of Disaster Risk Reduction process be it preparedness, mitigation or response. Mitigation measures are investment however response is expenditure. It is said that if you invest one rupee in mitigation it will save 99 rupees of response.” Urban flooding too is a problem of our times since large real estate organizations are in the fray; they should be preparing demonstrable models of building design and housing that are flood resilient, emphasizes Dr. Gupta from NIDM. One can see that *response* propels corporates into outreach. Both media coverage and interviews suggest that local businesses swiftly got into action and provided relief, while multi-national companies responded to the government initiatives. A news report (2018) published on the website www.economictimes.com informed that Hyundai Motor concentrated their outreach in ten villages around Sriperumbudur in Tamil Nadu to provide bedsheets and tarpaulin to safeguard against torrential rains. From evacuation to relocation to serving the community basic needs, corporate organizations followed the instructions provided by the government and started flood relief camps, medical camps, and ration facilities. Telecommunication companies in particular like Airtel and Jio intervened by providing data and connectivity in flood-logged areas. Though standalone initiatives have not been too many, most organizations worked to support the local administration and the government as per their planning in the form of flood-specific interventions like canoes and boats to bring people to safety. Dr. Anil Gupta is of the view that “most profound impact of outreach by brands is usually at the stage of response” when governments co-opt these corporates to impact rescue and respite (Interview Feb-March, 2022). Corporates gain as it increases brand salience for both the government and the community; however, communication has to be appropriate. A desire for immediate news development pushes the brands to send out outreach-related information to the media even when in the middle of the disaster, when relief and response work is still going on, often harming the corporate image than building it. Paarul Chand, Chief Executive Officer of PRmoment, narrates that “I have seen press releases being sent out presenting the flood relief work carried out by the brands,

in my opinion, no formal communique "is needed." So how do you communicate about the brand outreach to the world? she suggests "well, let the community served speak for themselves, just support the cause. Outreach work done should speak quietly" (Interview, March, 2022). It is back to lull during the *recovery phase*. While a few corporate organizations develop community networks with the help of local groups and NGOs are engaged in post-flood reconstruction and recovery practitioners and researchers believe that outsider brands or multinational companies who do have a production unit or distribution network in the area stop outreach programs or initiate short period out and bow out soon. Once the media attention withers away, corporates too leave the community says Dr. Samir Kapoor, a corporate communicator (Interview Jan, 2022). There are, however, corporate brands who work very hard to create community networks and provide care even when the disaster news dies down. Some companies have formed trusts and have identified water as a focus area in its sustainability program. Shah (2014) noted that one of the largest industrial conglomerates in India created the Tata Relief Committee (TRC) to respond to natural calamities. They were among the first responders toward charity, relief, and rehabilitation efforts during tsunami in Tamil Nadu and Aila Cyclone in West Bengal in 2008 and 2009, respectively. Their outreach is driven via disaster response programs. As disaster communication finds new media for reaction, advocacy, and engagement, corporate organizations use website-driven content blended with on-ground training and employability camps to show solidarity and allegiance with the flood-affected communities. As Annie Samuel advocates, "We need people to become change agents in order to build a sustainable disaster response to floods. Corporates in the flood outreach campaigns need to go beyond ration-relief and develop a vision alignment with the community" (Interview March, 2022) Empowerment via training and skill development of communities to build flood resilience and risk reduction is a necessary organ of outreach.

First hand communication in the empirical study leads to the identification of key elements in brand outreach. Besides money and materials, care, partnership, and empathy need to be integrated in brand outreach for flood-affected communities. Brands need to empathize with the affected families and communicate to them the planning aspects with them on rehabilitation. Manoj, an NGO worker in Thiruvalla, said that for the affected people, resettling needs empathy and soft handling, because it was their homes that they lost to floods. The problem, he said, arises because often the housing facilities constructed happened to be far away from their livelihood place; hence, they resist movement from their existing place (Interview Feb, 2022). In such circumstances, the companies need to map the community concerns and gather insights by listening to local issues and solutions from the people instead of a top-down approach where communication is one-way and non-participatory. Horizontal communication is best in flood-hit areas as local knowledge of terrain and weather helps the brands in designing its strategies so that funds, domain, and community knowledge result in robust flood management and care plans. It is about building networks of hope. Corporates are dependent on social sector organizations to reach to open channels of communication; what is required is

CORPORATE ORGANIZATIONS RELY ON NGOS FOR COMMUNITY NETWORKS IN FLOOD HIT AREAS

Fig. 2 An illustration of interrelationship between NGOs and corporate organizations. (Source: Jasdeep Kaur Chandi, Ph.D. scholar, USMC, GGSIPU)

commonality of vision. The NGOs who have already built a community network in the affected areas and the private organizations who are new need to collaborate early on with the aim to reduce the risk of floods (Fig. 2). Since corporate organizations have the funds and NGOs are adept at establishing the flow of communication and contact with the local opinion leaders, the two can complement each other so that an integrated outreach program can be launched in unison.

Any outreach in the future must involve scientific research to examine the efficiency of flood response toolkit. Various corporate organizations are providing research grant to disaster-themed researches. Outreach in the form of research by the triad of corporate brands, NGOs, and academic institutions is the potential future of community outreach. The future of brand outreach lies in continuity and sustainability as demonstrated by several companies after 2018. Majumdar elucidated that organizations of repute have dedicated teams or foundations involved in various community outreach programs throughout the year. Education, healthcare, skill development, and environment are few areas where organisations are engaged and involved in community outreach. Communication is a key element. While respect and trust of the community will come with day-to-day involvement, multimodal communication will create the desired cyclicity. Communication-wise, in addition to entertainment education programmes or social marketing campaigns for awareness on television and digital channels, use of closed message communication through WhatsApp and social media platforms like the Facebook and Twitter has proved to amplify the call for action as organic spheres of community formation and agenda

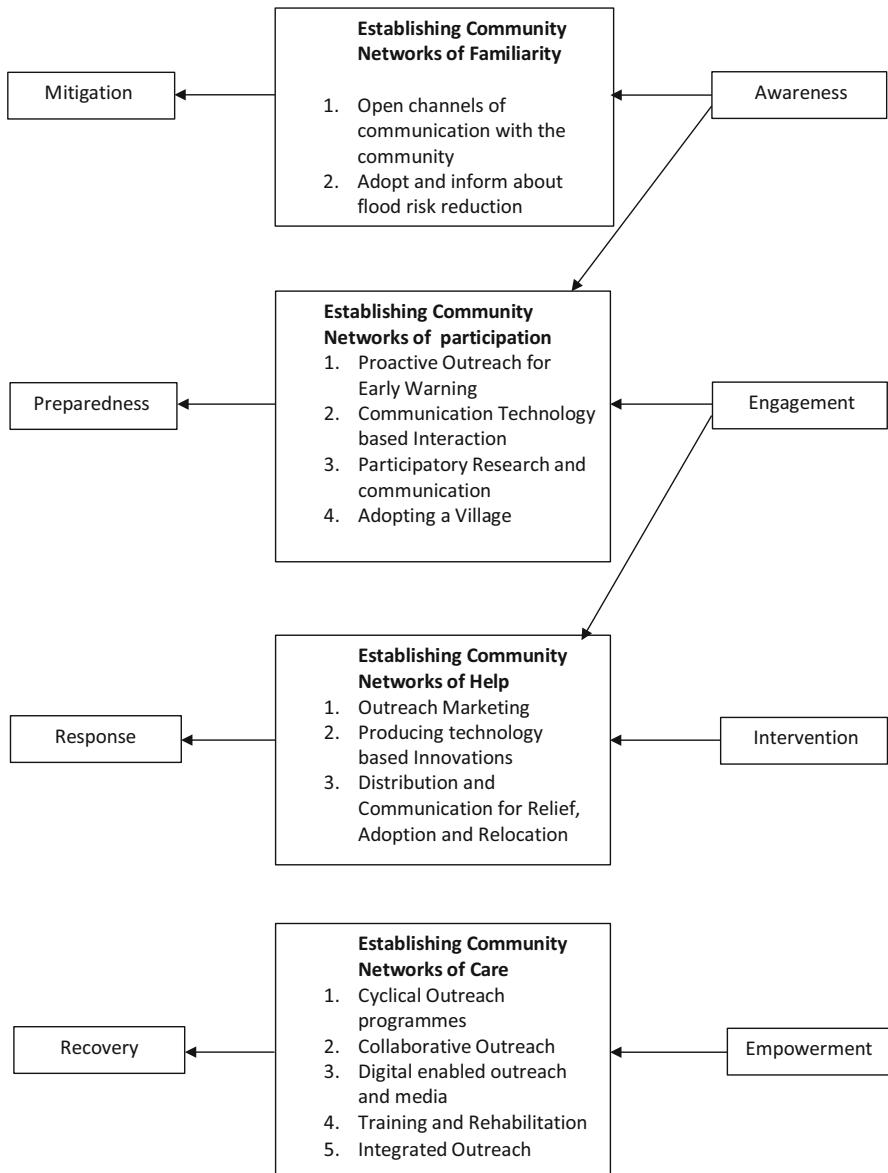

Fig. 3 Three pillars of outreach by brands w.r.t floods. (Source: Self-constructed)

building. On the basis of insights gathered, the case study on community empowerment developed by Shree and Sagar (2016) has been adapted to visualize the interrelationships between flood management stages, outreach strategy and tactics along with their functional role during each stage (Fig. 3).

Conclusions

Interviews with various experts and the media analysis suggest that corporate organizations adopt a non-structural approach to flood management that focuses on the reduction of flood vulnerability by increasing the resilience of existing buildings, preparedness, recovery plans and encouraging relocation to less flood-prone areas through flood education campaigns by providing funds for the local government and community to co-create campaigns with them. All the four steps in flood management cycle : Mitigation, Preparedness, Response, Recovery (MPRR) require corporate organizations to Create, Network, Associate, Advocate, and Act (CNAAA) by investing their emotions and cognitive competencies to develop interventions beyond financial aid. To be able to empower communities, the companies must gain in-depth knowledge about flood resilience. Relationship building is the key to effective outreach. The structural tension between corporate profit making and collectivistic responsiveness needs to be reduced by making non-profit activities become an indicator of brand performance where the prospective buyers judge it for collective values, deeds, and depth of involvement besides satisfaction obtained from the product. The guiding value of profit making needs to be redefined for a sustainable future. To put it succinctly, outreach by corporate organizations “is a delicate balance to strike, but foremost thing is that it cannot be about the brand, it is about the stakeholders, it is a question of support, neighbourly support, at times outsider support” as articulated by Paarul Chand of PRmoment, a PR consultancy.

Abstract

Climate change is gradually changing the contours of global climate, leading to significant changes in weather patterns across the world. Global warming is making glaciers recede and melt faster, causing the sea levels to rise alarmingly. Scientists have also found empirical evidence of changes in seasonal rainfall patterns. These changes in global weather have led to an increase in the frequency and scale of extreme weather events in almost every part of the world. As the global community grapples with its increasingly debilitating impact on the sustainability of human life and economic and development processes, they have made it imperative for media institutions worldwide to launch effective community disaster mitigation and preparedness strategies in disaster-prone zones. The recent climate-related disaster incidents have witnessed a relatively greater media attention with reporters being deployed in large numbers in disaster-affected zones. This has brought the complexities of gathering news in

H. S. Mishra (✉)
Editorial/News, New Delhi Television Ltd. (NDTV), New Delhi, India

a disaster zone under greater public scrutiny, making it imperative for media institutions to innovate and strengthen their existing news gathering processes.

The COVID-19 pandemic, the worst public health disaster in hundred years, has further highlighted the difficulties news reporters have to face in gathering news in a disaster zone. According to a study by Network of Women in Media, India, 625 journalists and media workers had lost their lives by March 18, 2022, in India since the first COVID-19 case was reported in Kerala on January 30, 2020 (Network of Women in Media, India. *In Memoriam: Journalists and media workers lost to Covid-19 in India*. From https://docs.google.com/document/u/1/d/e/2PACX-1vTkXC1UzWBeXiz39WHroeqleYml9WJu-SbQlu7nANl0zjC-c0jp_maF0XeTNAqOg/pub. Retrieved March 31, 2022). The perils of pandemic reporting have evoked a debate at a global level across media institutions and leading journalism schools on how to train reporters and media workers to safely cover a COVID-19-like pandemic in the future (Columbia Journalism School. *Reporting Safely on Covid During a Pandemic: Guidelines for CJS Students*. From <https://journalism.columbia.edu/reporting-safely-covid-during-pandemic-guidelines-cjs-students>. Retrieved March 31, 2022).

This chapter attempts to codify the primary role and responsibilities of journalists in a disaster zone, the logistical challenges they face while communicating risk, and the moral/ethical questions they have to face while gathering news on disasters. It delineates a standard operating procedure journalists must follow to combat threats to their physical safety and health and codify risks involved in a potentially hazardous/dangerous disaster zone. It also outlines a new disaster-sensitive methodology for conducting interviews with disaster victims with empathy and a greater sense of understanding of their trauma, loss, and pain. At the broader level, the chapter attempts to develop an ethical code for disaster-sensitive reporting and also argues for a humanitarian approach in disaster journalism.

Keywords

Disaster journalism · Media ethics · COVID-19 communication ecology · Crisis communication · Pandemic reporting

Introduction

Disaster journalism can play a very critical role in all three critical phases of disaster cycle: the pre-disaster phase, the disaster phase, and the post-disaster phase. Media institutions need to formulate a protocol for disaster reporting by codifying the roles and responsibilities of field correspondents. It should include a special “training module” to train and educate a set of reporters about different types of disasters, the logistical and physical challenges they could pose, their differential impact on the affected populace, and the safety protocol they must follow while gathering news. They must be trained to carry emergency kits and have evacuation plans since they work in a climate of fear and uncertainty in a disaster zone. The “training module”

should include basic knowledge about disaster laws and disaster management policies, including the official responsibilities assigned to different central and state agencies in the national and state laws. Such a long-term training and capacity building strategy is very essential to equip news correspondents and camerapersons with requisite basic skill base to report on disasters.

Pre-Disaster Phase

In the pre-disaster phase, the role of reporters primarily includes “forewarning” the society about the possibility of an impending disaster like a cyclone or flash floods in a given disaster-prone region. This would include prompt and timely broadcast of Met Department’s forecast and warnings about the above-normal rainfall predictions and the threat of flash floods, etc. Reporters also have a central role in disseminating critical information in a disaster-sensitive region to strengthen disaster mitigation and disaster preparedness measures and promote a risk reduction behavior among the common people. Media institutions need to critically evaluate the disaster mitigation measures initiated by state agencies at regular intervals and ascertain their efficacy. They also need to highlight policy gaps that exist in official policies and legal framework. This would help strengthen the resilience of communities residing in disaster-prone regions/areas.

Disaster Phase

When a disaster strikes a region or a given area, media institutions need to act with alacrity and speed in alerting both the community and state agencies about the scale and intensity of the disaster incident. They need to effectively “communicate risk” to the disaster-affected populace and disseminate primary information about the safety protocol they need to follow in a disaster zone and the institutional arrangements operational in “ground zero” to provide safe shelter homes. The information about the extent of damage in “ground zero” is critical as it would help direct the flow of rescue and relief operation in the right direction. The nature and extent of damage caused by the disaster incident need to be highlighted as it would provide primary information to state agencies about the kind of relief measures that are necessary to help the disaster victims. The degree of freedom and space reporters have in a given disaster zone will condition their ability to relay and disseminate information about the disaster to the larger mass. Media institutions need to keep their central focus on the disaster incident till they deem it necessary in national interest.

Post-Disaster Phase

After a disaster incident is over, the focus should shift on post-disaster recovery, rehabilitation, and reconstruction of lives and livelihood opportunities. At present, media institutions tend to shift their focus away from a disaster incident once it is

over. Disasters have a debilitating impact on the most vulnerable and poor sections of the community living in a disaster zone. They suffer irreparable losses, in terms of both their meagre resources and losing their modest livelihood opportunities. They are most insecure economically, and their interest and plight need to be highlighted. It is incumbent upon the media institutions to analyze and highlight the gaps wherever they may exist to ensure that every affected disaster victim is adequately rehabilitated. This would necessitate a public audit and assessment of the long-term rehabilitation and reconstruction measures required in the post-disaster phase. This would help expedite the recovery process in the disaster-affected community. Some disaster incidents like a devastating earthquake, floods, or a tsunami would require a short-, medium-, and long-term rehabilitation and reconstruction measures.

Ethics of Disaster Reporting

Media institutions should strictly follow the established code of ethics which outlines stringent norms for compliance with laws, rules, and regulations. The ethics of disaster reporting is essentially based on the principle of truth and fairness. Reporters should gather news in a disaster zone in an objective, fair, and credible way. They must be unbiased and honest in both gathering news and collating facts related with a disaster incident, as it would help direct relief and rescue work in the right direction. Unfair and biased reporting can negatively impact the disaster relief and rescue work as broadcasting wrong facts can mislead the disaster relief agencies and create panic in a given disaster zone. This could harm the credibility of both journalists and the media organizations they work for. The advent of new communication technologies, social media, and online news platforms has made disaster reporting one of the most complex professions in the world. It has brought a greater focus on tenets of media ethics and morality. Reporters are increasingly facing intense public scrutiny, as their work is now readily available to a large mass of people on both conventional and new media platforms on a real-time basis.

At the same time, media institutions must also employ stringent ethical norms for disaster news gathering. The failure to follow these ethical norms would open them to both public censure and greater intervention from media regulators. Considering the growing challenges posed by disaster incidents, media institutions will also have to innovate their news gathering processes, develop special investigative methods, and enhance the usage of new communication technologies apart from employing stringent procedures to follow media ethics and norms. They are increasingly under great pressure to be unbiased, fair, and independent in disaster reporting.

COVID-19 and Pandemic Reporting

The coronavirus pandemic outbreak has exposed the fault lines in crisis communication and public health communication systems worldwide, including in India. The failure of the disease outbreak reporting systems in most developed countries like the

United States, China, the United Kingdom, and Italy to employ emergency pandemic containment measures and effectively alert citizens to the danger posed by a highly infectious COVID-19 (coronavirus disease in 2019) has raised fundamental questions about the efficacy of their pandemic outbreak control protocols. This had far-reaching ramifications for the global community as it aggravated the pandemic crisis, leading to an unprecedented pressure on the most advanced healthcare systems worldwide (Sirleaf & Clark, 2021). During the first three waves of COVID-19 pandemic in India, the media institutions played a critical role in strengthening the public health communication systems by actively sensitizing common people about the urgent need to follow COVID safety protocols for self-protection.

In the first phase of a nation-wide lockdown starting with midnight of March 24–25, 2020, in India, the TV news channels, newspapers, web portals, radio networks, and social media platforms emerged as primary platforms for the dissemination of critical information related with COVID-19 pandemic. But as they disseminated critical information to the common people, they faced complex ethical, moral, and safety-related issues. At the larger level, the COVID-19 pandemic has posed a grave threat to the health of journalists who have battled many kinds of risks to their lives while reporting on the pandemic since its outbreak in Wuhan, China, in December, 2019. Reporting on the worst public health disaster since the Spanish flu influenza pandemic of 1918–1919 has proved to be extremely hazardous and challenging for reporters in every part of the world (Perreault & Perreault, 2021).

A COVID Risk Assessment Plan for Media

Reporting on a public health disaster like COVID-19 pandemic is potentially very hazardous for reporters, camerapersons, and other media workers. They have to work in a climate of fear and uncertainty which usually grips the pandemic-affected area/region. They have a relatively higher degree of exposure to the virus as they have to work and gather news and information close to “ground zero.” This necessitates that they follow a stringent safety protocol to manage risks and keep themselves safe and secure (Nieman Foundation for Journalism at Harvard, 2022). When the COVID-19 cases began to rise slowly in India in March, the central government imposed a stringent nation-wide lockdown starting midnight of March 24–25, 2020, and media institutions became the primary source of information on COVID-19 pandemic for hundreds of millions of Indians stranded at home. As cases rose in India and a large number of reporters and camerapersons contracted the virus, newsroom operations were affected across the media spectrum. Media institutions had to restructure and recalibrate their news gathering operations to respond to the challenge of continuing seamless broadcast of news as the shadow of COVID lengthened over India. They had to employ new methods of news gathering to keep journalists and media workers who were deployed in the field to do pandemic reporting.

In a short span of time, media institutions had to develop a risk assessment plan and a safety protocol to keep their office space and field staff safe. Soon, the tenets of disaster journalism were on display everywhere. To ensure adequate distance between reporters and camerapersons from subjects of news, the length of boom mikes of news channels were reformatted and made longer. Reporters had to follow a strict protocol of avoiding unnecessary interface with the public and avoid visiting their newsrooms. Many news channels made it mandatory for their field staff to travel in office vehicles to ensure their safety and security while carrying out news gathering operations. They were instructed to carry a COVID protection kit, which included basic sanitation materials including masks, headgear, and body coveralls. They were told not to visit any COVID care unit or health facility.

To limit the exposure of office staff, many media institutions made it mandatory for a section of the editorial staff to work from home. Only a bare minimum staff were allowed to work from office, to ensure that work space was secure and emergency operations could be continued in the case of an emergency. New communication technologies and mobile journalism allowed journalists living and working even within containment zones to ensure seamless broadcasting of news. Some news channels constructed makeshift studios at the homes of anchors and editors to enable them to safely report on the pandemic.

Despite these precautionary measures, a large number of journalists were infected with COVID-19, and news operations were affected across the media space. As per the database released by the Network of Women in Media, India (NWMI), 624 journalists and media workers had died of COVID-19 in India by February 21, 2022. Media institutions also had to grapple with complex moral and ethical issues while reporting on COVID-19 pandemic. The primary focus was on the need to protect the identities of COVID victims so as to shield them from any kind of social ostracization and stigmatization. Newsrooms had to reformulate their editorial policies to ensure that media coverage was fair, transparent, and inclusive all the time.

A Protocol for “Inclusive” Media Reporting

Media institutions have played a critical role in shaping the social discourse surrounding the COVID-19. Though the media reportage has conditioned the perception of common people about the threat posed by pandemic to public health, serious questions have also emerged about the nature of media reporting, especially during the “Tablighi Jamaat” congregation at Markaz Nizamuddin in March 2020. The Jamiat Ulama-i-Hind filed a petition in the Supreme Court alleging that an attempt was made to “demonize” the minority community in a section of the national media and sought directive to immediately stop dissemination of “fake news” related to the Tablighi Jamaat, which blamed the members of the religious congregation for deliberately spreading COVID-19. The apex court during the hearing observed that “Freedom of speech and expression is the most abused right in recent times” (Press Trust of India, [2020](#)).

This was not an isolated case in the world. In Ukraine, an LGBT group *Insight* filed a law suit against the head of Ukrainian Orthodox Church Patriarch Filaret for making an allegation during an interview to Ukrainian national TV network ‘Channel 4’ that COVID-19 pandemic was God’s punishment for the sins of men, the sinfulness of humanity...First of all, I mean ‘same sex marriage’. This statement exacerbated social tensions in the midst of the worst public health disaster in the last hundred years and was widely debated and reported by Ukrainian media organizations. It was widely perceived as “dangerous” by the LGBT community which could have led to more discrimination against them (Bacchi & Georgieva, 2020). As concern grew over stigmatization and stereotyping of “marginalized” groups in the media space, new theoretical parameters for media reporting also emerged. UNESCO issued a document titled “Guidelines for Inclusive Media Reporting on COVID-19” to warn the world community that “Disinformation, stereotyping, and stigmatization are extremely bad for outbreak control” (Tuneva, 2020).

An SOP for Reporting on Climate Disasters

Reporting on a climate-related disaster incident poses different kinds of complexities and challenges for correspondents. Climate-related disasters cripple critical infrastructure in the affected region, especially the urban and rural roads, national and state highways, transport services, power and water supply systems, mobile and communication, and other such critical infrastructure. Apart from incapacitating the rescue and relief measures after a disaster strikes a region, they also make it very challenging for news reporters to travel to “ground zero” of a disaster-hit zone. When Jammu and Kashmir suffered from the worst floods in more than a hundred years in the first week of September, 2014, landslides in several parts of the valley destroyed the road and highway infrastructure in several places. This made it difficult for the news correspondents to immediately reach the “ground zero” by road. I had to wait for more than 16 h at Palam Air Force Station to get a seat for myself and my cameraperson in an Air Force AN-32 transport aircraft to fly to the Srinagar Air Force Station.

When we landed in Srinagar Air Force Station late in the night, we had no access to any government or private transport facility. I had carried three sim cards but not a single one could be activated as most of the mobile towers had collapsed in flood-ravaged Kashmir valley. I realized that we had no contingency plan to manage the uncertainties and grapple with logistical challenges in a disaster zone. I struggled to contact security officials for a couple of hours who could guide us as where we could safely stay at night and how we could commute in the city which was flooded in several places at night. After several queries with security officials, we were transported to a CRPF official’s home where ad hoc arrangements had been made to house reporters and camerapersons for the night. The first morning came with far more complex challenges. The communication facilities had broken down, seriously complicating both the news gathering operations and the relay of critical information out of the disaster zone.

A reporter has to grapple with several logistical challenges – from restricted movement inside a disaster zone to accessing credible official communication in the wake of collapse of basic communication infrastructure. This also impedes the flow of news and information from inside the disaster zone. The collapse of mobile towers seriously impaired our ability to uplink our feed from disaster as broadcast journalists struggled with bottlenecks in sending the video feed to their news headquarters. This weakened the crisis communication processes in the disaster zone, as the flow of primary information about the unprecedented flood crisis was considerably delayed.

Disasters create a circle of uncertainty and despair in the worst-affected geographical area. The psychological impact of disaster tragedy on disaster victims is deep, and many of them suffer from acute anxiety and psychiatric issues. This necessitates the need to follow a disaster-sensitive (humanitarian) protocol to interview disaster victims. The news correspondents must approach disaster victims for an interview with empathy and utmost caution and care. They must be very sensitive to the sense of loss that pervades a disaster zone. They must carefully assess the trauma a disaster-affected individual or family has undergone before deciding whether they are fit for an interview.

There are issues related with the safety of life and health of news correspondents too as the fear of an epidemic outbreak is very high in a disaster. A few days after flood waters had entered the Srinagar city, I saw dead bodies of animals floating very close to the overflowing river banks. In one instance, the body was floating just next to a make-shift tent a disaster victim family had set up to survive the wrath of the floods just next to their flooded colony. The floods in Srinagar had seriously impacted the health operations in major hospitals at a time when the injured citizens needed urgent healthcare facilities.

Conclusion

The COVID-19 pandemic hit the world at a time when global community was struggling to cope with the rise in number of disaster incidents following abnormal changes in global weather. It was akin to a pincer movement as the media institutions were forced to deal with the complexities of gathering news on both COVID-19 pandemic and the climate-related disasters simultaneously. It caused immense hardship for news reporters deployed in disaster zones at the time of COVID-19 pandemic. For instance, when large parts of India were under stringent lockdown in May, 2020, the news reporters and camerapersons deployed along coastal areas in West Bengal and Odisha to report on the Super Cyclonic Storm Amphan, the strongest cyclonic storm in Bay of Bengal in last two decades, faced the twin challenge of protecting themselves from the wrath of both the Super Cyclone and the COVID-19 pandemic while gathering news in cyclone-affected coastal districts of West Bengal and Odisha.

The emerging post-COVID-19 world is all set to pose far more complex challenges for media institutions since the pandemic has debilitated the global economic

structures and unleashed an unprecedented socioeconomic crisis worldwide. The number of poor people facing loss of income, poverty, and hunger has increased manifold during the last 2 years. The economic recession during the pandemic has weakened the global community's efforts to attain targets enshrined in the United Nation's Sustainable Development Goals (SDGs), especially those related with combating hunger, poverty, and climate change. In the emerging post-COVID world, media institutions will have to recalibrate their priorities, mobilize global opinion toward combating poverty and hunger, and initiate institutional measures to strengthen their ability to work as a disaster watchdog. Also, the rise in the number of climate-related disaster incidents world over is gradually becoming a huge challenge for the global community. The Global Assessment Report 2022 (GAR2022) released by the United Nations Office for Disaster Risk Reduction has revealed that between 350 and 500 disaster incidents were recorded every year in last two decades. GAR2022 has warned that the number of disaster incidents is expected to increase to 560 per year by 2030 (United Nations Office for Disaster Risk Reduction, 2022). To cope with this growing challenge, the media institutions must initiate policy measures for the capacity building and training of news correspondents and camerapersons.

Abstract

Communication holds the key to an efficient disaster management. The aims of crisis communication broadly are to inform, educate, and communicate with various stakeholders with a view to create resilience and confidence among them and communities at large. The people in charge of communication need to be trained specifically in communicating on disasters during various stages, viz., pre-disaster, disaster, and post-disaster. Among the various stakeholders who need to be sensitized and trained, the most crucial include the civil servants, who are called upon to administer/manage disasters, the information public relations personnel in the central and state governments who disseminate information to the media on behalf of the government, disaster management teams at ground zero and at head office level, the communities at the grassroots level, and last but not the least the media persons who need to be exposed and sensitized to the disaster management emergency response system and the preparedness of the administration in dealing with any kind of situation so that their reportage is balanced.

It is generally believed that truth is an easy causality during a crisis. Therefore, it is important that efforts be made to disallow the formation of grapevine, misinformation, and fake news. Media often takes the center stage post a disaster. The news media by its nature is critical of those who are in charge of disaster management to find the underlying cause of the tragedy. Misinformation, disinformation, and scare mongering during disasters are a common occurrence; therefore, managing perceptions is important to ensure that the situation does not get out of hand. In the smart cities' context, it is expected that these are equipped with zero-failure communication dissemination apparatus and mechanism.

The chapter would explore the multi-pronged challenges in disaster management but most importantly how the people in charge of disaster management and communication are to be trained to do a professional job. The chapter would provide an outline of the training contents on disaster communication for various stakeholders.

Introduction

Disasters are the most dreaded phenomena, but inevitable. About 190 million people are directly affected annually by emergencies due to natural and technological hazards, with over 77,000 deaths (<https://www.unrr.org/event/unrr-geti-who-unitar-e-learning-course-resilience-local-governments-multi-sectoral-approach>). The impact may

vary, depending on the level of preparedness, availability of resources, flexibility in decision-making, and most importantly an understanding of what would be in public interest. In other words, in a disaster situation, an avid understanding of the phenomenon of *intent versus public interest* and the honesty of purpose on the part of the authorities would determine how a disaster situation was handled.

Most natural disasters, if probed deeply, are indeed the outcome of humankind's blatant exploitation of nature. The flagrant exploitation of natural resources and the larger ecosystem, which includes, among other things, the building of large-scale hydroelectric power projects, deep in the mountains by changing the course of rivers, the blasting of mountains to make way for tunnels and power installations, the displacement and uprooting of thousands of families to make room for building infrastructure; the nuclear power proliferation, exposing thousands of habitants to radio-active emissions; more and more coal-based thermal power projects emitting deadly smoke from their chimneys; the denuding of forests for modern living and maintaining modern lifestyles, thus taking away the natural habitat of the wildlife, the greenhouse gases from burning fossil fuels for electricity, heat, and transportation, are some of the irreversible consequences of development, resulting in natural and manmade disasters. The future generations shall have to pay a heavy price for the "development" unleashed by the present one. The Father of the Nation, Mahatma Gandhi, once said, "There is enough for everyone's needs, but not greed." Who plays with the environment more, the rich or the poor nations may be an issue of academic debate, but the more important question for us to ask ourselves is, are we prepared to cope up with the current and impending disasters? How supple, flexible, and plausible are our systems and processes that would help countries and communities to bounce back, post a disaster, is what we need to work on.

Building disaster-resilient cities is the new buzzword. The smart cities are expected to be strong enough to withstand the impact of disasters. There are varying views on whether there should be standard indicators for the smart cities to be followed. For one school of thought, the indicators have to be standard to gauge their resilience and effect of disasters. The other school of thought believes that indicators should ideally depend on the vulnerability of various regions to natural and manmade disasters, the socioeconomic divide, and the resources to handle disasters, among others. While the disaster management authorities have started including the role of communication in building disaster-resilient cities in their plans, the role of independent news media has not yet been fully understood, realized, and explored. If there is anything that acquires center stage, post a disaster, it is the independent news media. Therefore, understanding the information needs of the news media and making them an important stakeholder and partner in reaching out to communities are as important as information dissemination from the authorities through various means including the mass media. A synergy between the supply and demand sides of information thus would go a long way in effective disaster management.

Role and Scope of Capacity Building in Managing Disasters

Within the context of disaster risk reduction, the *Sendai Concise Guide on Disaster Reduction* defines capacity development to be “the combination of all the strengths, attributes and resources available within an organization, community or society to manage and reduce disaster risks and strengthen resilience” (<https://www.unrr.org/publication/sendai-framework-disaster-risk-reduction-2015-2030>). The UN General Assembly Resolution A/RES/71/276 endorsed the recommendations of the Open-ended Intergovernmental Expert Working Group on Indicators and Terminology Relating to Disaster Risk Reduction on 2 February 2017. United Nations General Assembly, 2017. Report of the Open-ended intergovernmental expert working group on indicators and terminology relating to disaster risk reduction). Capacity development according to these guidelines covers four major areas, viz., *Leadership* (leadership development programs, partnership and coalition building, and identifying and supporting champions of change), *Institutional strengthening and development* (including strategic planning or reform, establishing disaster reduction risks, legislative actions, decentralizing initiatives, and organizational effectiveness measures among others), *Knowledge sharing* (education- and training-based capacity development to focus on building and enhancing individual organizational awareness and knowledge, supported by a combination of classroom-based education and informally through social marketing, on-the-job training, coaching, and mentoring and organizational-level actions that need to support information gathering, sharing, and dissemination), and *Accountability* (creating and strengthening coalitions and networks, conducting public information campaigns or townhall meetings) (*Ibid* p. 19).

In this chapter, we shall take for discussion the training and education-based capacity building needs of various stakeholders on communication and the engagement with news media on the following indicators:

- Current information and communication management practices relating to disaster at national, state, district, and grassroots levels
 - Identification of problems, challenges, and roadblocks in managing communication relating to disaster management
 - Identifying the training needs of various critical stakeholders
 - Reviewing current practices in media in covering disasters
 - Recommending a course curriculum to suit the role and scope of various stakeholders in managing disaster communication
-

Why Those in Charge of Disaster Management Need to Learn About Media and Communication?

Communication is one of the most important ingredients in management, and disaster management needs it all the more as the situation arising out of a disaster is often extraordinary which, among other things, requires reaching out to those

affected by that particular disaster with information on various measures, including mitigation and rehabilitation. Some researchers have reported improvements in disaster-related knowledge and behavior in their study of communication imperatives in natural and manmade disasters across many countries (Bradley et al., 2014). The scenarios in various countries, at the same time, were so disparate that there in general was an absence of high-quality robust trials relating to disaster communication that needed to be remedied. For the study, the research team searched 5,224 unique articles, of which 100 were judged as potentially relevant. Out of the sample, 25 studies met the inclusion criteria, and 2 additional studies were identified from other searching. The studies evaluated interventions in all the four stages of the disaster cycle including a variety of manmade, natural, and infectious disease disasters. The countries from where the studies were picked included Australia, Canada, Hong Kong, Taiwan, Singapore, Japan, China, Egypt, Iran, India, the Republic of the Congo, Haiti and Caribbean islands: St. Vincent and the Grenadines, and Turks and Caicos Islands. The research study suggests that the digital media may provide better research opportunities. To quote, “Modern internet-based interactive social media present opportunities for risk communication, and may facilitate evaluation because it may be possible to invite recipients to complete knowledge or behaviour questionnaires, or even to request position-based information from mobile devices” (Bradley et al., 2014).

A 2008 field survey among information and public relations officers from 11 states, including the vulnerable ones, from India brought home some findings and insights that are important from the perspective of the need for synergy among various people in charge of disaster management.

Research Insights from the Survey

In-depth interviews with the key stakeholders were conducted to assess the problems encountered by them in disaster communication. The findings indicated the following issues from among various stakeholders from within the media ecosystem:

Information and PR Officials

- Reluctance on the part of various departments to pass on information to information officers
- Time constraint to handle crisis communication amidst other work responsibilities
- Non-availability of officers to provide latest information on the disaster, when needed
- Lack of manpower and logistical support in handling crisis
- Problem in getting authentic and accurate information on a regular basis (i.e., updates on the number of casualties, the impact and extent of damage)

- Urgent need for training in new communication technology and tools
- Lack of clarity on confidentiality and sensitivity to information

Media Persons

- A general lack of trust about government data
- A belief that government conceals more than shares
- Competition among media, an important factor in being “First with News”
- Perception that government officials were not efficient and quick in sharing information
- Lack of guidelines or policies among media organizations for covering disasters

Policy Makers

- A general lack of trust in the efficiency of information officers
- Lack of synergy in the work of civil servants and information officers
- Lack of appreciation of media’s need for information
- Critical of media going overboard in making news sensational

Most information and public relations officers spoke of a continuous trust deficit between them and the bureaucracy, represented by young district magistrates from the Indian Administrative Services (IAS), often on their first field job, who would not consult with them on media strategies or interface but take their own call. Many among them, in 2008 when digital media and communication technologies were coming up, spoke of the need to augment their skills especially in handling technology (In a USAID consultancy project on capacity building in training and education in disaster management undertaken by the present author, in 2008, these findings emerged in the baseline survey. A training needs analysis of 11 states, including in-depth surveys in vulnerable states, like Assam and Gujarat were used to draw conclusions and suggest recommendations for developing the course curriculum. The consultancy was taken by her when she was a professor at the Indian Institute of Mass Communication.).

Media information is a strong facilitator for creating awareness on disasters. Preparedness includes action to reduce risks, which also needs community intervention, resources, and motivation. An inclusive approach is, therefore, called for, to cover vulnerable groups, such as women, children, elderly, and physically challenged.

Technology has a great role to play in connecting with the stakeholders, but it is of equal importance that those in charge of communication understand the media functioning and its sociology and ideological leanings, besides acquiring the knowhow in preparing media and communication strategies, including outreach, social mobilization, and participatory research especially at the grassroots level, where the media reach and accessibility are often low. The disaster management

authorities generally use multiple media platforms to reach out to various stakeholders, both at the time of issuing warning and also in the aftermath of disasters. Some empirical studies suggest that the coming of the digital media, specially the mobile phones, has greatly facilitated both the authorities in reaching out to people and the communities in knowing about the impending disasters when the authorities have used the mobile technology to connect with vulnerable communities in the far-flung areas. Community radios at the grassroots level have also contributed phenomenally in disaster times. The state of Odisha in India is a test case on good practices in achieving successful community outreach through technology in disasters caused by cyclones, especially after the super cyclone in 1999. The cyclone unleashed vast devastation, but a huge learning for the state, nonetheless.

Information Overload in Crisis Times

Every crisis brings with it an information galore, making it often challenging for an average news consumer. For instance, the Covid-19 pandemic that broke in 2020, not sparing any country, was followed by what the critics termed as “infodemic,” with all kinds of information pouring in from sources from all over the world, making the understanding of the situation challenging for people, amidst the fear of what the coronavirus was capable of unleashing in their lives. When a crisis strikes, the independent news channels, newspapers, and online news portals may not necessarily have the same perspective on disaster handling as that of the authorities, which becomes a cause of friction between them.

The media outlets generally send their team of reporters to the disaster site, who besides their own understanding of the situation also gather insights from the local sources and anonymous voices, which may or may not find resonance with government's perspective of the situation. In an era of digital media and a hyperactive social media, thousands of videos get uploaded by many including the local people who happen to be at the site of the disaster, resulting in a huge information overload post a disaster. This also would mean a huge surge in misinformation, disinformation, fake news, and mischief mongering by vested interests and anti-social elements. Bad news often spreads like wildfire; therefore, it is important that the authorities handling the crisis also understand the dynamics of news making and its dissemination in disaster management and engage with the stakeholders accordingly.

Over a period of time, some media academics and journalists have prepared training modules in conflict reporting (Howard, Ross). This has been done in a hope and belief that a reliable media that is neutral, accurate, and objective would be able to help in better management and governance (Conflict-sensitive reporting-UNESCO.pdf). Grief journalism is becoming one of the latest areas of study in disaster times. If the survivors feel the brunt of apathetic and insensitive reporting many a time, the other side of the argument is that journalists who cover disasters see so much suffering and antipathy that it tells upon their own mental health, which should also be a cause of worry and an important area of addressing and research.

Ethical Discourse: Media's Responsibility

Media has a responsibility to report with high ethical and professional standards. Referring to a number of past instances when the media reportage was inciteful and inflammatory contributing to fuel conflict in a number of crisis situations, the International Media Support's (IMS) booklet underlines the importance of being fair in disaster reportage (<https://www.mediasupport.org/wp-content/uploads/2012/11/ims-csj-handbook-2004.pdf>). News media is expected to not only use the highest standards of professionalism but also appreciate the need for sensitive reporting in times of grief and devastation.

The Press Council of India, a Media Watch body has issued the following *Norms of Journalistic Reporting* in covering natural calamities and disasters:

PCI Norms on Reporting on Natural Calamities

“(i) Facts and data relating to spread of epidemics or natural calamities shall be checked up thoroughly from authentic sources and then published with due restraint in a manner bereft of sensationalism, exaggeration, surmises or unverified facts.

(ii) Natural or man-made hazards become disasters through acts of commission and omission of the society. Therefore, the disastrous impact can be minimized by preventive action taken by all the stakeholders including the media.

(iii) Media should give wide publicity to the do’s and don’ts and the potential benefits of disaster mitigation so that the society follows them before, during and after the occurrence of the disasters. People should be detailed on standard guidelines. The issues of children and women which are the most vulnerable groups during and after disaster should be handled carefully by the media.

(iv) It is necessary to have complete cooperation between the media and all governmental and non-governmental agencies. The extent of the coordination and cooperation between them determines the nature, the degree and the scale of the preparedness to prevent or meet the disasters” (p.35)

Source: <https://presscouncil.nic.in/OldWebsite/NORMS-2010.pdf>

Diminishing Trust Levels

It is commonplace to find an uneasy relationship between the media and the government in times of disasters. Media in general comes under fire from the authorities for sensationalizing news, thus aiding in creating adverse public opinion against those in charge of managing disasters. The news media on its part believes that the government and concerned authorities hide more than share. The Covid-19 public health emergency proved beyond doubt an open unease between the two institutions. Hundreds of FIRs were filed against journalists, and some were also taken into custody on charges of spreading “fake news.” In a study of 125 fake news dispatches in India during Covid-19, it was found that digital media accounted for over 94% share, while the mainstream media was at 5.6% (Al-Zaman, 2021). Fake

news, the scholar argues, produces tension, misunderstanding, and disbelief, especially in the digital age and social networking age.

The audio-visual medium, especially the television channels, is often criticized for being apathetic and insensitive to victims' state of mind, when they interview the survivors and the next of the kin of the dead. The late Joseph Scanlon, Professor Emeritus and Director of the Emergency Communications Research Unit at the Carleton University, in his insightful paper writes that whatever the perception about the media on their disaster coverage, there was no doubt that the media played an important role at all the stages of a disaster, but the media itself may not be aware of it. To quote him, "Mass media participation is critical, for example, for effective warning and the mass media may be the glue that binds societies in certain occasions. Yet the media are also responsible for many of the misconceptions that exist about disaster, misconceptions that may lead to errors of judgment when disaster strikes. A review of texts suggests Journalism scholars are unaware of this. Strangely, the one area where media scholars have shown the most concern – the way journalists deal with survivors and relatives of victims – is the area where the limited available research suggests the media are not as guilty as painted" (<https://training.fema.gov/hiedu/docs/emt/scanlonjournalism.pdf>. Accessed 18 Dec 2019).

Social Media: The Game Changer

The onset of social media, in a way, has changed the paradigm of disaster communication. If, on the one hand, social media is criticized for provocative "user-generated content" and posts coming from anonymous sources, social media, on the other hand, provides opportunity to disaster managers to access posts of those in distress and the community voices and concerns, identify sources, and also know the severity of the effect, besides identifying and reaching out to communities with succor and rehabilitation. The wide reach and access of social media can be befittingly used during all the stages of disaster management, viz., preparedness, response, and recovery (Chan, Christopher Jason). The social media tools and strategies thus can be made use of for information dissemination, disaster planning and training, collaborative problem-solving and decision-making, and information gathering. (<https://www.oecd.org/governance/risk/The%20role%20of%20Social%20media%20in%20crisis%20preparedness,%20response%20and%20recovery.pdf>)

Is Disaster Management Equivalent to Reputation Management?

Post a disaster, often hounded by an aggressive news media and a possible adverse public opinion, the government and disaster management authorities get worried about their image. They see in it the politics of malice and the handiwork of the vested interests. Media is often browbeaten for reflecting what the government

would not like the public to read and watch. A crisis brings with it myriad perceptions, based on many factors, such as grapevine, skewed media coverage, fake news, misinformation, and disinformation, among many others. Therefore, it is very important for the government and concerned authorities to handle perceptions that are not based on informed stimuli. Wrong perceptions float around because there could be delay in information sharing from the official sources. Hence, it is essential for the government and the concerned disaster management authority to manage perceptions while these are at an embryonic stage.

What are the lessons for disaster/crises managers?

- Develop a strategy based on worst-case scenario
- The vital importance of pre-thinking
- The initial critical few moments when a crisis breaks are very important.
- Know the media mind and their stand on the issue
- Isolate the crisis team from the daily grind.

Failure in a crisis handling happens due to one or all the following reasons:

- Lack of openness, honesty, or availability of the spokesperson in the initial period
- Failure to prepare for the worst case
- Failure to share information timely to let the grapevine develop
- Failure to communicate honest, human emotion and concern
- Short-sightedness of the organization in putting long-term goals before short-term goals

Government's Outline on Capacity Building Strategy

The National Disaster Management Authority (NDMA) in a white paper prepared between 2012 and 2014 has outlined the following key elements on capacity building through training and education:

- *Capacity development goals of training are clearly defined and agreed in advance by the concerned stakeholders.*
- *Training is context specific and need based.*
- *Institutional arrangements are streamlined.*
- *A system to assess training needs is developed and operationalized.*
- *A system to vet and approve training designs is devised and put in place.*
- *A system to track the efficacy and impact of training is developed and piloted (<https://nidm.gov.in/pdf/ncrmp/Deliverable%2015.pdf>).*

The chapter noted that most of the above outlined elements either were missing or rarely were included in the training practices related to disaster management and disaster risk reduction at the national, state, and local levels.

Preparing Stakeholders in Disaster Communication

Disaster management is a trans-disciplinary area that needs a complete synergy among various departments and institutions handling the emergency and preferably allowing a one-window approach for the disaster survivors. Therefore, it is important that those in charge of disaster handling be trained in crisis communication.

Based on the stakeholder theory, it is believed, much can be achieved in managing a disaster, but only if all the stakeholders are recognized, well-coordinated, and respected (Fazari & Kasim, 2019).

Defining Stakeholders

Drawn from economics in the context of commercial enterprises, the expression “stakeholder” over the years has become universal when defining important constituencies across economic, political, and social spectrum. Milton Friedman’s theory that gained ground in the last century posited in the context of organization that shareholders were but just one of the stakeholders. The ecosystem, he argued, included anyone who had invested in the company, was involved, or was affected, including the company, employees, vendors, suppliers, special interest groups, and government agencies, each one qualifying to be among stakeholders. Friedman’s argument was that a company would succeed only if it satisfied all its stakeholders and not just those who had invested in it (Friedman, 2002). Bucholtz and Carroll speak of the three values attached to the stakeholder model that include *descriptive* value which provides language and concepts to describe organizations, *instrumental* value that relates to the fulfillment of the organizational goal aimed at growth and sustainability, and normative value, the presumption that stakeholders have inherent value (Donaldson & Preston, 1995).

The NDMA’s training and capacity building referred above has recommended training in media and communications, but only for the information and PR officers (I&PR) at both the central and state levels. The counterargument to this is that the I&PR officers no doubt are the experts appointed by respective governments, but they are not necessarily the spokespersons. The media interface often is done by ministers and bureaucrats. At the district level, it is the district magistrate, an administrative services officer who is in charge of the overall disaster management and also all communication activities. Similarly, panchayat heads, local police, para-military forces, and disaster management teams are important links in the effective management of a disaster, who many a time are called upon to share information and speak to news media and communities. The chapter underscores the importance of training for all the stakeholders in information dissemination, communication and media handling.

Let us see who these stakeholders are and what they must learn on crisis communication.

Users of the Curriculum

Some of the critical stakeholders who need to understand and assimilate media and communication dynamics and currents and under-currents of communication in disaster situations include the administrators/government (grassroots/state and center), information and PR officers at central and state levels, disaster management officers, hospitals, and emergency services. In a disaster situation, many other organizations such as the corporate sector, NGOs, CSOs, Resident Welfare Organizations (RWAs) and people at large need to be looped in for extending support in cash and kind, including providing volunteers and blood donation, if required. Last, but not the least, an important stakeholder is the news media as it serves not only as a conduit between the authorities and the people, but it has a watchdog function. The reporters and news editors need to be exposed to the working of the disaster management authority and sensitized on disaster reporting.

Keeping in view the core area or expertise of various stakeholders, the following training programs and course modules are suggested. The training curriculum has been designed in a manner that it would address the training needs of the key stakeholders in the disaster communication process.

1. Government information and PR officers
 2. District magistrates/civil servants
 3. Block development officers/panchayat heads
 4. NDRM disaster teams/police and para-military personnel
 5. NGOs/civil society organizations
 6. News media reporters and news editors
-

Training Approach

The training of various stakeholders outlined above is recommended to be approached in two ways:

- (a) Organizing training of various stakeholder groups individually in exclusive module(s) on disaster communication with a general run on disaster management per se.
- (b) Including an extensive module on disaster communication in the orientation training programs of the administrative services officers (IAS), Indian Information Services (IIS), and other services of the central and state governments that are relevant to disaster management.
- (c) These short-term programs can be orchestrated and curated under the aegis of the National Disaster Management Authority through a media institution of repute.

Faculty: Who Could Ideally Undertake Such Capacity Building Training Programs

Disaster management is a trans-disciplinary field; therefore, any capacity building program ideally would have a cross section of experts drawn from across diverse fields. For a course in media and communication, the suggested faculty resources can be drawn from media schools, disaster management faculty at premier universities that run courses in disaster management, well-known NGOs and CSOs with a proven record and scholarship in disaster management and research, and the NIDM. The faculty should also include media practitioners who have covered disasters and are well-versed in both classic and online media.

The country has over 300 universities, covering central, state, and private ones that have media schools/departments spread throughout the various states, employing hundreds of faculty members. The NDMA can shortlist a few media schools based on their credentials and draw a list of “master trainers” and “resource persons” who can work on the training modules in details, providing both the conceptual framework and innovative pedagogical tools and hands-on skills.

Objectives of the Proposed Course Curricula

The Disaster Communication course curricula for the various stakeholders has been developed keeping in view the following broad objectives:

- **Developing a proactive communication approach during disasters to:**
 - Warn people about impending disasters
 - Prevent any vacuum in communication
 - Prevent grapevine from becoming overactive
 - Provide timely information based on facts during all the phases of disaster management
- **Sensitizing various stakeholders on the role of communication in disaster management so that they can:**
 - Provide information on mitigation, rehabilitation, relief, evacuation, and compensation when the disaster strikes
 - Mobilize support (monetary, technical, and moral) from citizens and organizations
- **Synergizing the efforts of various stakeholders during disasters to:**
 - Achieve greater efficiency in the work-related areas of disaster preparedness, response, recovery, mitigation, and reduction
 - Enable them to collectively work better toward the common goals in disaster management, especially rehabilitation of victims
- **Enhancing the capabilities and skills of stakeholders in handling media with a view that:**
 - Media can be involved in playing an active role in disaster management

They understand the information needs of media and are able to cater to them more effectively

- **Improving their communication skills and other soft skills so that:**

Government officials are able to address the concerns and queries of people more effectively and promptly

Senior government officials/leaders are able to communicate clearly, precisely, and most importantly empathetically with various people involved, thus avoiding unnecessary panic and chaos during disaster situations

Recommended Modules: An Outline

The following modules suggest the conceptual framework and thrust areas:

Information/Public Relations (I&PR) Officers of the Central and State Governments

Objective: To enhance the capacity of I&PR functionaries in disaster communication, with a focus on writing for the media, media handling, use of communication tools, digital media, and development of soft skills

Duration: 2–4 weeks

Core Modules

1. Understanding disasters and disaster communication
2. Task and responsibilities of an I&PR person
3. Planning and preparation in disaster communication
4. Understanding media: evolution, sociology, and the broader ecosystem
5. Digital media skills: functioning of online news portals, social media platforms, user-generated communication; challenges, feedback/interface with online communities
6. Evaluation and impact of media narrative

Skill Enhancement Modules

7. Understanding news/conceptual framework
8. Writing for media (press releases, press note, press brief, backgrounders, rejoinders, etc.)
9. Media handling (organizing news conferences, interviews with journalists, follow-up, strategic handling of critical media)
10. Public awareness through public information campaigns and “third-party endorsement”
11. Using ICT and soft skills
12. Community outreach and social mobilization

Pedagogy

Facilitator-led discussions; case studies with audio-visual clips of disasters that have occurred in the past; classic cases of success and failure in handling disasters; examples of media coverage; role-plays; hands-on skills; simulations; mock drills; group work; best practice sharing; case studies; ad campaigns during disasters; examples of pamphlets/handouts that can be made on spreading awareness

Teaching support of disaster management experts to be enlisted for modules 1 and 2 in the core category

District Commissioners/Civil Servants

Objective: As it is used for objectives, in my view it is fine. It is used in the similar manner for Objectives for various courses

Duration: 3–5 days

1. 1. Leadership skills
2. Understanding media
3. 3 Understanding news
4. Perception management
5. Media interface (hands-on skills on how to prepare for a media interview, press conference, and media brief)

Pedagogy

Facilitator-led discussions; sharing of case studies: classic failures and success stories; role-plays; simulations

Faculty

The faculty would ideally consist of media academia of great standing; media practitioners who have covered disasters and well-versed in upcoming and new media, management, and practices; and most importantly senior officers from the NDMA.

BDOs/Panchayat Heads

Objective: To enhance the capability of BDOs/panchayat heads in community sensitization and mobilization in disaster preparedness, rehabilitation, and providing emotional support to traumatized people through folk and other interpersonal media

Duration: 3–5 days

1. Understanding disasters
2. Need for leadership among panchayat heads and BDOs
3. Mobilizing communities/self-help groups

4. Use of folk media in sensitizing communities on disaster preparedness
5. Learning the use of IT, community radio, and mobile phones in reaching out to communities
6. Preparing stories for community radio from grassroots

Pedagogy

Role-plays; mock drills; video clips/films on disaster management

Faculty

District magistrate, I&PR experts, and folk artists drawn from within communities and local resources

Civil Defense, Police, and Para-military Personnel

Objective: To sensitize them on the need of communication in times of disaster; understanding media and its role in disaster management and community outreach; art of listening and articulating their concerns and sharing with authorities

Duration: 1 week

1. Disasters and role of communication
2. Understanding media
3. Leadership skills
4. Community outreach
5. Media literacy

Pedagogy

Mock drills; video clips; films on disaster management; facilitator-led discussions

Faculty

NDMA officers, I&PR experts, and media faculty

NGOs/CSOs

Objective: To sensitize NGOs working at the grassroots level and in urban areas on disaster communication; to mobilize local community organizations and public to participate in the disaster management; and to developing skills in media interface

Duration: 3–5 days

1. Understanding disasters
2. Community mobilization
3. Enlisting volunteers, mock drills
4. Media literacy

5. Use of IT, community radio and mobiles, community newspapers/wallpapers, and pamphlets in reaching out to communities

Pedagogy

Facilitator-led discussions; role-plays; mock drills

Video clips; films on disaster management

Faculty

I&PR experts and folk artists drawn from within communities and local resources

Media Personnel

Objective: To sensitize media reporters on disaster management, sharing standard operating practices (SOPs) followed in disaster management, thus facilitating media to report disasters sensitively and authentically and source information efficiently and from credible sources

Duration: 2–3 days

Core Modules

1. Disasters and disaster management preparedness at macro and micro levels
2. Disaster communication, stakeholder segmentation, and challenges
3. Speaking for the voiceless
4. Grief journalism: legal and ethical perspectives
5. Skill enhancement modules (writing, editing skills)

Pedagogy

Facilitator-led discussions; case studies of recent disasters: critiquing media coverage; case studies of international disasters; interactive VCD/DVD comprising a tool kit on disaster management; dos and don'ts in disaster coverage (participative discussion); hands-on skills; simulations; role-plays; mock drills; sensitization on appropriate use of terminology; footage keeping in view public's sensitivity

Faculty

Senior members of academia drawn from media schools and NDIM senior officers in charge of strategy and operations

Conclusion

There are two realities: one, the world is faced with many current and future disasters, both natural and manmade that need to be addressed and handled to save the humanity of anxiety, sufferings, deaths, and destruction; and two, we live in an age of information and a global world where the problems are not bound by geographical boundaries. Information dissemination is central to an effective disaster

management. The digital media with a large chunk of user-generated content, *sans* editorial filters, often has the potential to create difficult situation for both the disaster managers and the news consumers. It is therefore important that information disseminated from various sources not only is fact-based but at the same time is empathetic and sensitive. Effective communication is a learned discipline. Disaster management, a trans-disciplinary phenomenon, requires synergy not only from among various disciplines but also with various stakeholders. Preparing them for effective communication and media handling will surely contribute toward handling disasters professionally and more importantly empathetically with a human touch.

Abstract

Population explosion, unplanned urbanization, overutilization of resources, unscientific development in risk-prone zones, environmental degradation, unprecedented climate change, and rapidly changing demographics reflect the increasing vulnerability of India to debacles. The development of multi-hazard surroundings to which hundreds of thousands of human beings in the world are uncovered highlights the significance of making sure that the affected population is better prepared. The aggregate of human and financial losses, collectively with redevelopment costs, make disasters both humanitarian and economic problem. Even as sizable scientific and material progress is made, the loss of lives and property due to disasters has not yet reduced. Hence, media and communications forge a link between the public and government to bridge this gap. It is the core element and performs a crucial function in rescue, response, and recovery.

operations. In a country like India, media provides a large potential and probability for enhancing disaster resilience and chance to manage and increase the capacity building for early warning and education. As a result, with righteous use of media and communication, the emergency organizations can strive to prepare a resilient community with increased capacity building resources.

Introduction

With increasing trends of debacles over the world, mankind has been exposed to huge loss of lives and property. Estimating the frequency and severity of debacles occurring all over the world, it becomes of utmost importance to strengthen the preparedness, risk reduction, and response strategies. The increasing use and acquaintance with technology even at the remotest places have made the world just one click away. Taking advantage of the technological resources, it will help not only to prepare for a better understanding of disasters but also to strengthen the mitigation measures leading to disaster risk reduction. These advancements have changed and improved the scientific findings, increased capacity, and have created better networking and connecting, better resource utilization and mobilization, and greater participation and awareness aiming for sustainable development.

Although disasters cannot be avoided, the risk of calamities can be avoided by taking proper risk reduction measures. Mostly all the developing countries in recent times have faced increased frequency, intensity, dimension, and trends of disasters be it natural or anthropogenic in nature. Hence, the need for proper **risk reduction** along with proper preparedness and management approaches has to be emphasized upon.

Among the various aspects of disaster management, communication plays an important role as it connects affected people and communities with relief measures. Communication and information dissemination is the foundation of all the activities of the society. But many a times, communication becomes one of the biggest menace when it fails to address and implement disaster solutions, both conceptually and their application. Better communication is achieved when the communication done is accurate, reliable, and accessible. The ever-increasing demand for efficient communication in disaster risk reduction and management has aimed to achieve minimum rate of fatalities and damage to property. Communication is an important key in all the phases of disaster, i.e., pre, post, and during the disaster, and gives a way forward to make a resilient society against various debacles. It therefore would be prudent to choose that media channels that will provide not only information but share real-time reality of the situation. It further reflects the need to have accurate and efficient communication via proper media channels to reduce the confusion which otherwise

may lead to dissemination of inaccurate mitigation measures. Various factors highlighting the urgency to work on the process of media and communication are efficient logistics distribution, synchronization, and multi-sectorial cohesion.

Need for Appropriate Media and Communication

Many a times in debacle-like situations when warnings are not accessible in remote areas, not accurate enough, not in vernacular language, and not consistent, then media and communication play a crucial role of disseminating the correct information to the society and communities at the time of catastrophe.

Communities are so overwhelmed in the face of a disaster that they often lose track of progress and development. Therefore, it is important to gather correct and accurate information by reaching out to the local native people in addressing their problems. Communication and media should not just focus on the lives and property lost but must also aim at preventing further damage by proper dissemination of warning and information. The inability of society to cope up further makes the development and economy paralyzed, unraveling the unpreparedness of our society.

Media and communication play a vital role in preventing humanitarian mis-happenings by providing not only timely information about various remedial actions to address the emergencies but also help in demonstrating how resource allocations can be achieved. Media plays an important role in transmitting information and facts from the place of disaster incident to the targeted society and specific communities.

With an increase in disaster-like situations all over the globe at an alarming rate, it is only important to have a better and effective communication with an aim (1) to understand the types of media platforms, their access, and reach among the target communities and (2) to know how frequently or timely information and relevant data can be provided by various media platform.

Types of Media: Effective Advances in Communication Technologies

During the onset of a disaster, it is of utmost importance to keep the morale of the affected community high, create self-confidence in them, prevent panic, and maintain law and order by assuring and making available all the necessary help readily and quickly. Disaster media and communication implies to pass on the “right information at the right time.” In a country like India, there are three major types of media: (1) electronic media (TV, radio, electronic gadgets), (2) print media (newspaper, leaflets, hoardings, brochures, and pamphlets), and (3) satellites, wireless communication, and DTH. Technology has a crucial role in information gathering, analysis, and dissemination during all the phases of a disaster. Hence, when integrated with considerable linkages (Fig. 1), media can work effectively for resource utilization (Table 1).

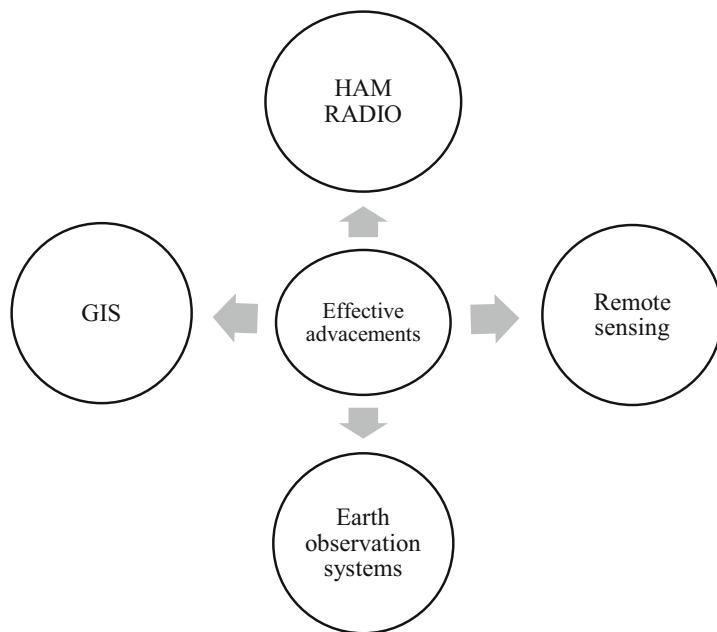

Fig. 1 Advances in communication technologies

Table 1 Linkages between communication technologies and hazards

Hazards	Satellite information	Print media	Radio and TV
Floods	Meteorological data	Education for evacuation and local strategy for communities	Dos and don'ts, transmitting warnings and alerts
Volcanos	Thermal sensor data	Education for impacts and localization of resources	Transmitting warnings
Earthquake	–	Educating about construction evacuation and building codes	Dos and don'ts during all the phases of disasters
Cyclone	Meteorological data	Transmitting current status and evacuation	Warnings and alerts

1. HAM Radio

With effective and sophisticated technology, the electronic media has made the world to connect just by one click, but imagine a scenario when all the ground-level communications and network gets disrupted during calamities like earthquakes or floods. During such emergencies HAM radios can play an important role.

HAM radio, also known as amateur radio, is the use of radio frequency spectrum for purposes of wireless exchange of messages, self-training, and emergency communication. HAM radios have been of great help at the time of natural calamities. HAM radio, in fact, has become a core requirement for reaching out to remote areas. HAM radio involves the combined use of two units – transmitter and receiver – which facilitate a two-way communication across the world. HAM radio station acts as “second saviour” of communication when existing public communication links fail to act.

2. Remote Sensing

By developing the potential of early warning systems with the help of space technology, mobilization of resources including communication and tele-medical services can be carried out. Remote sensing provides a database from which the evidence left behind by past disasters could be interpreted. When disasters affect large areas, no other system works efficiently than remote sensing which provides a matching spatial coverage. Remote sensing allows for the monitoring of event during the time of occurrence; hence it gives a real-time scenario which when communicated leads to more timely remedial measures.

3. Earth Observation Systems

Satellite communication capabilities, fixed and mobile, are vital for effective communication, especially in data collection, distress alerting, mapping locations of calamities, and coordination of relief operations in the field. Satellite maps help to map the situation which can be further communicated and implemented at the place of the disaster. Communication satellites play a vital role in providing information about disaster warning and relief management.

4. Geographical Information System (GIS)

GIS uses geographical and computer-generated maps as an interface for integrating and accessing massive amounts of location-based information. It is of great help in communication of disaster preparedness and response.

Conceptual Framework

All catastrophes are chaotic and dynamic in nature creating emotional, physical, and social disorder. It is always a matter of concern that often panic, somehow wholly and truthfully unfounded, resulted in deadly disaster loss. The community, being the first responder, reacts immediately at the onset of a disaster. Hence, for effective management and communication, it is important to correctly channel and portray the use of media so as to not only disseminate information but make sure it is an accurate one which would provide a way forward to the affected people. Media and communication act as core aspects in the exchange of information and social interactions. The concept is to make sure that the disseminated information is not sourced, hoaxed, invalid, and uncertain with a potential to create chaos and fear which is troubling to the society (Fig. 2).

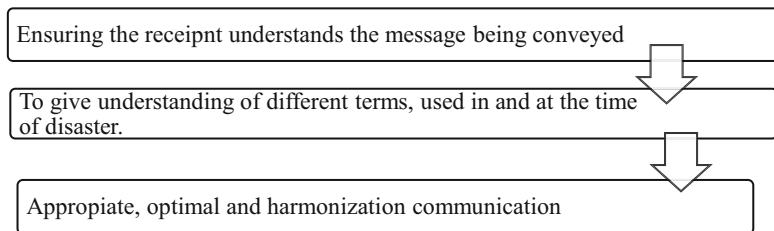

Fig. 2 Information dissemination method

Disaster Communication Via Proper Media Channels

This includes mainstream broadcast media such as TV, print, and radio, direct mailers such as flyers and brochures, outdoor mediums such as billboards, collaterals such as airline and bus tickets; and localized tools such as community radio, person-to-person contact, street plays, and other community events.

Disaster communication plays a vital role in raising awareness among the communities regarding different types of disasters, disaster-prone locations, and disaster preparedness and mitigation, along with survey of post disaster need assessment in a sustainable way to minimize the potentials hazards with the active help of media.

Well-planned interactions with the media could be of great help to bring down the intensity of damage done and will help to save greater amount of life and property. Hence passing of information and facts is very important in the process of efficient media and communication in disaster management.

Effective communication acts as a liaison between the government and local communities to ensure proper allocation of resources. The need for proper media and communication channels for disaster communication arises out of the ever-increasing scenario of misinformation, disinformation, rumour-mongering, and fake news, which has multiplied with the augmentation of social media platforms and user-generated communications.

It observed that media was negatively correlated with the perceived information obtained via social media and the traditional methods of communication and media were preferred more. While the social media has its own benefits of providing real-time experiences faced by the communities at the time of disaster, it also helps them to receive an immediate response action (Fig. 3).

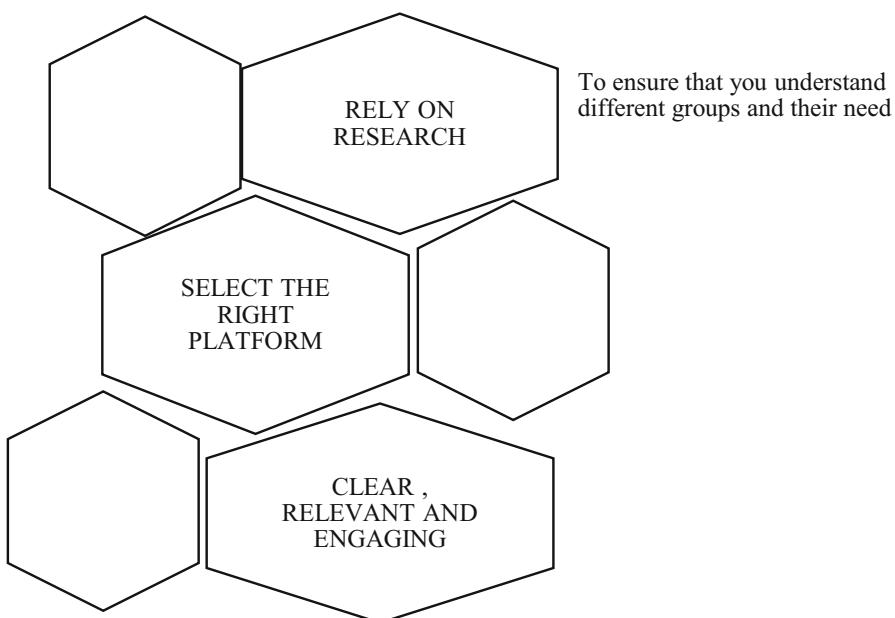

Fig. 3 Ways to communicate about risk

Role of Information Dissemination in Disasters

It is a well-known fact that information is power and influence. The perception of disaster risk and its management plays a vital factor in the better understanding of behavioral and emotional decisions that the affected communities in the disaster-prone areas are likely to make. Some of the anthropogenic and natural disasters are preventable; hence the media can educate and forewarn people about the consequences of human movements and operations that may lead to catastrophes.

Media provides information on the pertinence of securing communication, identifying susceptible spots, and focusing attention on vulnerable or disaster-prone areas. The role of information dissemination becomes important as it can be circulated using different mediums keeping in mind individuals of different ages, genders, regions, etc.

Media and Tools for Dissemination of Messages

Different tools and technologies are required to effectively and properly disseminate messages and information to a large section of target audience, down to the last mile. The major thrust of the strategy focuses on opting for measures and tools that have a direct impact on the specific group or community helping all the divisions and sectors of the society. This includes mainstream broadcast media such as TV, print,

and radio, direct mailers such as flyers and brochures, and outdoor mediums such as billboards.

When observed it came to light that most of the rural people and also communities living in remote areas predominantly relied on television broadcasts and Doordarshan, the public broadcaster, to obtain disaster information. Young section of the communities often obtained information with a constant use of social media and the Internet.

Need of the Hour: Effective Electronic Media

While natural disasters cannot be prevented totally, their effect and impacts can be mitigated or reduced to a large extent. Hence, timely and adequate actions are required which calls for a large amount of resource allocation, which can be mobilized quickly and judiciously if a correct information dissemination path is to be followed. With the help of timely, accurate, and accessible news media primarily electronic media, a real-time scenario is exhibited, and hence prompt actions are now available which lessen the loss of human life and property. It is not possible to publish and outsource print media, i.e., newspapers and leaflets, every half hourly or hourly basis, but it is definitely possible to warn and inform mankind with continuous update via electronic media either by running news, graphical representations, or scrolls. It is not only easily accessible but the quickest and fastest means of information dissemination and plays a pivotal role in saving lives. Besides this, electronic media plays an important role in the societal governance, as it helps to educate the society at every stage of disaster and plays the role of an educator in the aftermath of a disaster. Furthermore, modern communication tools come in the form of state-of-the-art technology at low cost options at every phase of disaster (Fig. 4).

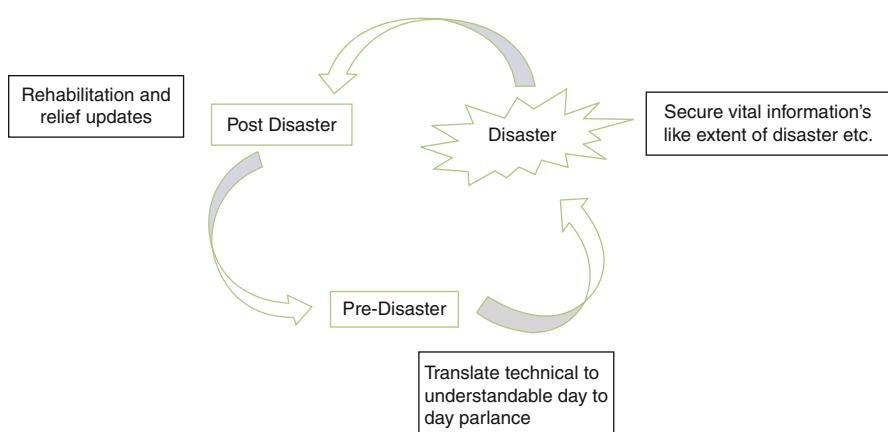

Fig. 4 Role of electronic media at all phases of disaster

Challenges and Limitations

One of the greatest barriers which needs to be addressed is language in disaster management. It has been observed that local language is mostly used and preferred by a large section of the most vulnerable within the communities. Therefore, all efforts reaching out using local/vernacular language and material prove to be effective. Language becomes a major bottleneck in the remote or inaccessible areas. People who have rudimentary knowledge or no understanding of the language suffer the most. Also the print media is not only inaccessible but it is so difficult for newspapers or leaflets to reach the remote areas, especially in times of floods and cyclones as often the roads and trails are disrupted compared to areas which are well connected otherwise.

Positive Outcomes

It is usually the media that declare debacle as official.

- Instant information with real-time scenario
- Continuous, factual and timely dissemination of information
- Greater coverage of spatial area making it easier to locate the places with intense disaster effect
- Timely resource allocation

Negative Outcomes

- Hoax, miscommunication
- Exaggeration of incidents and events
- Sentimental issues and irresponsible covering
- Uncontrollable price rice
- Bias reporting

Conclusion

Regular monitoring, interaction, and communication with media before the debacle proves to be an effective pathway for information flow and provides a way forward in the aftermath of a disaster. Despite all that it is not always possible to prevent all the losses and damages, even with effective implementation decisions, but honest efforts pave the way for future learning. Such efforts also create positive perceptions about the authorities in the public mind. Losses and damages often are unequally distributed across systems, regions, and sectors and are not comprehensively addressed by current financial, governance, and institutional arrangements, particularly in vulnerable developing countries. Hence, an inclusive disaster risk reduction

(DRR) has to be focused on. Continuous monitoring and evaluation is mandatory to strengthen the preparedness and rehabilitation processes with the help of media and communication. Media acts as a quick vehicle in the dissemination of information on risk reduction in the best, quick, accessible, reliable, and accurate manner. Hence, it should be used effectively and efficiently.

Inclusive governance that prioritizes equity and justice in adaptation planning and implementation leads to more effective and sustainable adaptation outcomes. Although media and communication play an important role in disaster risk reduction, they are not synonymous, and without compromising the integrity of either one, much can be done to communicate to the public.

With proper integration of media and communication, integrated, inclusive planning and investment in everyday decision-making about urban infrastructure, including social, ecological, and gray/physical infrastructures, can significantly increase the adaptive capacity of urban and rural settlements. Development processes are timely, anticipatory, integrative, flexible, and action focused; therefore proper dissemination of information becomes imperative in disaster management.

Abstract

It is not only because of climate change that many societies today face devastating hazards, but Asian countries like Vietnam must deal with emergencies that can have natural or man-made causes. Examples include earthquakes, tsunamis, floods, landslides, droughts, and pandemics, such as the recent COVID-19.

Therefore, disaster risk management is an important task for all governments and the mass media. Not only does the mass media play a pivotal role before, during, and after disasters occur, but it is also responsible for raising awareness of potential risks and measures to mitigate the negative impacts of disasters. Monitoring disasters and initiating countermeasures are two particularly important tasks for all those responsible for disaster management.

However, how can the media gain the trust of the public when reporting on disasters that are already taking place? Even nations with a wealth of experience in dealing with such events, such as the USA and Japan, have faced criticism from the public in the past for their disaster communication strategies. After all, although people often panic during catastrophic events and then demand

immediate responses, it always takes time to determine the reasons for a disaster and for communicative problems as well. This chapter discusses disaster communication in Vietnam by analyzing a specific case, the communication during the 2020 floods in central Vietnam. It then identifies the causes of the communication problems and proposes solutions to the challenge of securing public trust. The research results are based on the analysis of disaster communication in the context of a case study; methodologically, we rely on content analysis.

Keywords

Disaster · Communication · Trust · Vietnam

Introduction

The role of communication has been acknowledged as vitally important in disaster management. Communication before, during, and after a disaster can generate warnings, connect victims, and contribute to dealing with disastrous consequences. A trustable and easily accessible system of communication is also key to disaster recovery of a community. Communication plays an indispensable role in all four stages of disaster management, including alleviation, preparation, response, and restoration.

The emergence of new media and information technology in the past two decades has resulted in a larger capacity of the communication system during a disaster. Paul (2001) analyzed the contents related to disaster rescue, pinpointing an exploration into the theoretical definitions regarding interaction and applying that interaction in disaster communication. Tanner et al. (2009) analyzed disaster communication on the Internet, focusing on mobilizing information in local television channels in relation to disasters in order to make implications for health protection and for future emergencies too. Muller and Gawenda (2009), in a report by the Centre for Advancing Journalism in Melbourne University, have pointed out six roles of Australian newspapers in reporting news concerning local forest fires. Veil (2012) analyzed the strengths and drawbacks of lacking mutual knowledge among administrators and news correspondents in reporting on the emergent state. Meanwhile, the author emphasized five benefits that newspapers can offer the public. This trend of research was clarified in the context of Japan by Takekawa (2014), after the catastrophic 2011 earthquake and tsunami.

Several authors discussed disaster communication in a world where communication is rapidly changing (Haddow and Haddow 2013). In this chapter, the authors have indicated the roles of technical tools, applications, and new connections between public and local authority in emergent and disastrous events. Haddow and Haddow also pointed out ways for effective disaster communication, comprising transparency, increasing accessibility, and information reliability together with the collaboration between different means of communication. Particularly, the role of

social media in disaster communication was analyzed in thorough detail by Palen and Hughes (2017), Lovari and Bowen (2019), Mirbabaie et al. (2021), etc.

Several research studies have centered on the practical dimension of communication in reporting on disasters. Ewart and McLean (2018) classified news reporting on disasters into three major categories: planning for pre-disaster news reporting, exclusive interviewing and writing skills about disasters, and editing and production. Peterson (2014) compared the means of news reporting on the storm Katrina and Haitian earthquake to indicate the political characteristics of disaster news. News reporters need knowledge about the history, economy, and politics of the affected area. Lacking these knowledge types possibly leads to cliché and shallow manners of disaster news reporting.

The definition of disaster, disaster management, and disaster communication in Vietnam is mainly based on the United Nations' perspective. A disaster is "a serious disruption of the functioning of a community or a society involving widespread human, material, economic or environmental losses and impacts, which exceeds the ability of the affected community or society to cope using its own resources" (ISDR, 2009, p.9). Several scientific studies on disaster communication include Phan Van Tu (2016), Nguyen Minh (2020), etc. Vietnam Disaster Management Authority has issued the handbook of instructions for information and communication in disaster prevention (Vietnam Disaster Management Authority, 2021). Nevertheless, Vietnamese has witnessed no research study exclusively centered on disaster communication and trust via case analysis in terms of disaster communication in Vietnam.

In this chapter, initially, we list the common disasters in Vietnam, followed by a case study on disaster communication in Vietnam – news reporting on the floods in central Vietnam. This region frequently suffers from natural catastrophes, one of which is the heavy rainfall and flooding in 2020 that caused a substantial loss of human resources and property. 355 news articles on this catastrophic event in *VnExpress* and *Tuổi Trẻ Online*, two news sites with the largest numbers of readers in Vietnam, from 2020 to 2021 were analyzed. In addition, readers' responses and comments were included in the analysis. We aim to answer the following questions: How do the public form their trust in disaster communication? What do they trust and why? What makes them skeptical about information reliability? How do administrators and news reporters gain the public's trust?

Disasters in Vietnam and the Role of Media

According to the United Nations Office for Disaster Risk Reduction (UNDRR), in the past 20 years, globally, it is estimated that disasters of various types have increased by 75%, caused over one million casualties, and affected over four billion people, which leads to the economic loss of approximately 3000 billion USD. A noticeable fact is that Vietnam is among the five countries which suffer the most severely from global climate change. "Within 20 years, disasters such as storms, floods, landslides... have caused more than 13,000 deaths, property damage of 6.4

billion USD, and threatened approximately 60% of land and over 70% of the population with disastrous risks" (Nguyen Van Ngan, [2021](#)).

On April 22, 2021, the Prime Minister issued Decision 18/2021/QĐ-TTg to set regulations on predicting, warning of, and reporting on disasters and disastrous risks for activities on preventing, responding to, and minimizing the damages of disasters and restoring disastrous consequences in Vietnam. Accordingly, the disasters that need predicting, warning, and reporting comprise the following: (1) storms and tropical depressions; (2) heavy rains, floods on the rivers within the territory of Vietnam and rivers that flow through multiple countries, flooding, flash floods, landslides, and subsiding land; (3) heat, droughts, and saltwater intrusion; (4) strong winds from the East Sea and fogs on the East Sea and the land of Vietnam; (5) sea level rising higher than coastal areas and islands of Vietnam; (6) whirlwinds, lightning, hail, cold, and frost; (7) forest fires due to natural causes; (8) earthquakes whose magnitude is greater than or equal to 3.5 (on Richter scales or equivalent) and which can affect Vietnam; (9) earthquakes whose magnitude is more than 6.5 Richter or equivalent and which occur in the ocean and can cause tsunamis affecting Vietnam; and (10) tsunamis which occur due to earthquakes in remote oceans and can affect Vietnam.

According to the statistics published by the Central Steering Committee for Natural Disaster Prevention and Control, "in 2020, Vietnam witnessed 16 types of disaster, specifically: 13 hurricanes in the East Sea; 264 strong winds, whirlwinds, heavy rains in 49 provinces and cities; 120 flash floods, landslides; particularly, the heavy rains and floods occurring from the 6th to 22nd of October 2020 in Central Vietnam; 86 severe earthquakes, droughts, saltwater intrusion, sliding riverbanks, shores, subsiding sea dams in the Mekong delta" (Nguyen Van Ngan, [2021](#)).

"Communication plays an important role in providing information, knowledge, skills, raising the public's awareness, and effectively contributing to disaster prevention and control, which partially minimizes the number of casualties and residents' properties" (Vietnam Disaster Management Authority [2021](#)). Accordingly, communication is required to meet the demands for rapid speed, high accuracy, and accessibility to diverse groups of the public. The content should be brief, understandable, and appropriate based on each type of disaster, conditions, characteristics of the local area, and each group of residents. The content and frequency of information should be frequently updated and adjusted accordingly to the duration and risk levels of the disasters. It is required to use all means including direct and indirect ones to communicate, including television channels, voice channels, printed newspapers, electronic newspapers, social networks, direct communication, local methods, etc. The format and content of communication products should be attractive, appealing, and accessible to target groups and use local dialects in the areas for the ethnic minorities.

Communication prior to the disaster plays an educational role in terms of laws, knowledge, skills, and solutions to preventing and controlling disasters. During the disaster, communication must provide information related to the conditions, duration of the disaster, cautions, instructions on coping with the disaster, managing and steering activities, and coping with disasters at multi-administerial levels. After the

disaster, communication reflects the activities of steering and restoring disastrous consequences, instructing on solutions of restoration, and lessons which can be withdrawn. Therefore, the Government of Vietnam has issued quite detailed and specific guidelines concerning communication activities for disaster prevention and control. In the next part of this chapter, we will analyze a specific case in terms of communication during a disaster, in more detail, that is the information communicated on *VnExpress* and *Tuổi Trẻ Online* in relation to the floods in 2020 in central Vietnam.

Disaster Communication: Case Study

VnExpress is the online newspaper with the largest number of readers in Vietnam. In 2020, the newspaper attracted over 40 million frequent readers, more than 10 billion views, and five million comments from readers. The age range of readers is from 18 to 60 years. *Tuổi Trẻ Online* also remains one of the five online newspapers which have the largest numbers of readers in Vietnam. According to Similarweb, in March 2022, total visits *VnExpress* was 148.3 million and total visits *Tuổi Trẻ Online* was 61.5 million. Hence, disaster communication in these two newspapers has profound impacts on the public.

In relation to the floods in central Vietnam, statistics points out there were 184 articles on *VnExpress* and 171 articles on *Tuổi Trẻ Online* with the content as follows (Fig. 1).

As there was not a big gap between the number of articles regarding the disastrous flood on *VnExpress* and on *Tuổi Trẻ Online* (184 and 171, respectively), both

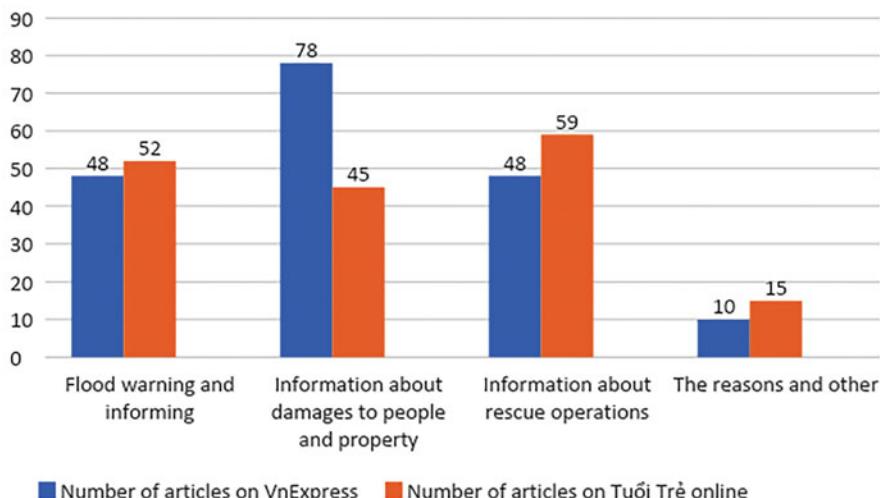

Fig. 1 The articles related to the disastrous floods in central Vietnam on *VnExpress* and *Tuổi Trẻ Online* in 2020–2021. (Sources: Statistics by authors)

newspapers' efforts in spreading awareness of the importance of this topic were relatively similar. The content of each subject of the two newspapers has various similarities – communication in terms of floods and heavy rainfall in central Vietnam before, during, and after the disaster. We will now analyze the content of these articles in more detail.

Firstly, the warnings and informing related to the floods and rain accounted for 26% of the articles about the disastrous floods and rain on *VnExpress* and 30% of those on *Tuổi Trẻ Online*. The two newspapers frequently updated their readers of the heavy rainfall, rising flood levels, and warnings for areas against the risks of landslides. Specifically, a series of articles in October 2020 on *VnExpress* gave warnings against flooding and rainfall. "The central is facing 3 tropical depressions" (*VnExpress*, October 10th 2020), "Tropical depression in the East Sea" (October 10th 2020), "Storm weakens, another tropical depression in the East Sea" (*VnExpress*, October 14th 2020), "Hurricane Nangka weakens to tropical depression" (*VnExpress*, October 14th 2020), "Tropical depression entering the East Sea" (*VnExpress*, October 15th 2020), "Heavy rain continues in the central" (*VnExpress*, October 19th 2020), "Severe hurricane at level 8 approaches the East Sea" (*VnExpress*, October 20th 2020), "Heavy rain in the central, rising flood" (*VnExpress*, October 29th 2020), etc. In comparison to *VnExpress*, *Tuổi Trẻ Online* also published a larger number of news articles about the warnings of the floods and rain, provided information about the conditions and duration of the disaster, and instructed on coping with the disaster, in order to meet the public's needs and expectations of this topic. October 2020 alone, in which the disastrous weather phenomena occurred in central Vietnam, witnessed the publication of 30 articles on *Tuổi Trẻ Online*, which continuously warned and informed readers of the rains and floods.

Secondly, the damage to persons and property by heavy rains and severe flooding took up the largest proportion of the content in disaster communication (42%) on *VnExpress*, attracting the greatest interest and number of readers' responses. Seventy-eight out of 174 described damage to persons and property in the disaster. On October 15, 2020, *VnExpress* reported: "Two landslides buried 30 people within two nights"; 70 commentators expressed their grief toward this loss. On October 18, 2020, *VnExpress* published three articles concerning the damage due to the disaster: "Floods and rain devastated the central for 12 consecutive days," "Floods and rain cut off many areas in the central," and "84 casualties due to floods and rain in the central." A couple of days afterward, *VnExpress* continuously informed readers of the disastrous damage: "102 deaths, 160,000 houses flooded due to floods and rain" (October 19th 2020), "Hill slide destroys border guard station Cha Lo" (October 10th 2020), "People's great loss due to the great flood" (October 21st 2020), "Residents cross the river on cable lines" (October 22nd 2020), etc. On October 28, 2020, *VnExpress* wrote the article "Record-breaking numbers of the floods and rain in the central," but the records had sad connotations: "Flood on the Kien Giang River (Le Thuy district, Quang Binh) peaked at 3.91 meters in 1979 but at 4.88 meters on October 19th 2020, causing continuous flood." On November 28, 2020, Deputy Minister of Agriculture and Rural Development Nguyen Hoang

Hiep spoke to *VnExpress* about the damage and lessons from the floods and rain in the central: “The disasters have become more severe; never in history have floods and rain occurred as severely as this time. 249 deaths, 57 missing, over 1500 houses collapsing; nearly 240,000 houses damaged or removed of their roofs. The substantial damage to agriculture includes the loss of 4000 hectares of rice, 7600 hectares of vegetables, 12.670 hectares of fishery; 38.500 cattle, 3.200.000 poultry; 165 km of dams in the sea, riverbank, 50 km of damaged revetment; 88 sliding spots along the shore with the total length of 141 km. The total loss is estimated at 30.000 billion VND. These are uncompleted statistical data. The hurricane and floods have long-lasting effects uncountable in numbers” (Tat Dinh, “Damage uncountable in numbers due to the rain and floods in the central,” *VnExpress*, October 29th 2020).

On *Tuổi Trẻ Online*, 26% of the articles of disaster communication reflected the severe damage to persons and property; October 2020 alone witnessed 25 articles about this topic. Many of the articles described the great grief of the families who lost members right in the titles: “Mountain landslide, families separated during the floods in the central” (October 10th 2020), “Gruesome grief in Tra Leng: Student collapses on returning to her village to look for her parents” (October 29th 2020), “Landslide in Tra Leng: It couldn’t be more gruesome” (October 30th 2020), etc. (Fig. 2).

Thirdly, on *Tuổi Trẻ Online*, articles about rescue activities made up the largest proportion, accounting for 35% of the articles about the disastrous floods and rains in central Vietnam. Fifty-nine articles on *Tuổi Trẻ Online* were centered around this topic, affirming the steering role of the government in while-disaster rescue operations (“Helicopters to distribute aids for residents in isolated areas due to landslides,” October 23rd 2020; “Prime Minister Nguyen Xuan Phuc: Financial aids for residents to repair houses,” October 30th 2020), the participation of the health sector

Fig. 2 Flood in Quang Ninh district, Quang Binh province (Photo: Đức Hùng. Source: *VnExpress*, 19/10/2020)

Fig. 3 A military helicopter and its crew braved strong winds and rough seas as they lifted a crew member of Vietship 01 up from the ship. As the rescue mission took place, storm Linfa was heading to the central region (Photo: Giang Huy. Source: *VnExpress*, 3/11/2020)

(“Ministry of Health demands activation of mobile units for aids in the flooded area,” October 29th 2020; “Ministry of Health supplies more medicine for Quang Nam, assigning 7 units to the central,” October 30th 2020), the involvement of foreign affairs sector (“Units for foreign affairs commits to support residents in the central,” October 19th 2020), the engagement of the military (“Region 5 Command Unit together with 200 soldiers search for the 45 buried people in the landslide area,” October 29th 2020; “Thousands of residents, soldiers climb hills to carry aids to the isolated areas,” November second 2020), etc. In addition, support and aids come from people across the country, businesses, international organizations, governments, etc. (Fig. 3).

Twenty-six percent of the articles about disaster communication on *VnExpress* analyzed aids and rescue operations (48/184 articles), equal to the number of those about warnings and information about the rain and floods in the central region. The articles on *VnExpress* centered on the rescue operations by the government: “Thousands of billion spent on repairing roads after the rain and floods” (October 19th 2020), “Soldiers help residents restore their lives after the floods” (October 25th 2020), “Prime Minister claims no hunger, no homelessness” (October 24th 2020), “Propose 6500 tons of rice for 4 provinces in the central” (October 26th 2020), etc. Additionally, aids and support for residents in the central were from the whole country, artists working inside and outside Vietnam (“Artists donate for residents in the central,” October 13th 2020; “Vietnamese artists in America call for donations for residents in the central,” October 20th 2020), women (“Women cook thousands of meals for flooded people,” October 20th 2020), youths (“Youth rescue flooded people to be awarded the title Youth with Bravery,” November 16th 2020), national and international organizations (“UNICEF aids the central with 61 billion VND,” November 17th 2020), etc.

In the two newspapers, another subject about the disastrous rains and floods in the central area is analyzing their causes. *VnExpress* published 10 articles about this subject, and the number was even 15 for *Tuổi Trẻ Online*, taking up 6% and 9%, respectively, of all the articles about the disaster. The newspapers attempted to indicate the causes in the articles “Mass flooding in the central because hydropower plants discharge floods through the spillway” (*Tuổi Trẻ Online*, October 11th 2020), “Why continuous rain and floods?” (*VnExpress*, October 15th 2020), “Controversial effects of small-scale hydropower plants on rain and floods” (*VnExpress*, October 30th 2020), etc. Mr. Nguyen Van Huong, Head of the Weather Forecasting Department, National Centre for Hydro-Meteorological Forecasting, indicated four causes for the heavy rain in the central region. The first cause is the intertropical convergence (of the Northwest and Southwest winds) starting from the Bengal Bay, traveling across central Vietnam to the Philippines. The second cause is hurricanes and tropical depressions. The third one is the cold air, which is constantly supplied from the north, together with a moisture-rich East wind, all of which form a huge moisture-rich air that was measured 5.000 meters from the surface. All of them were situated in the central, causing more rainfalls and continuous floods. The fourth cause is the terrain blocking winds – the Truong Son Range, which blocked the cold air and Northwest winds flowing to the central, forming a strong atmospheric convection which results in heavy rain (“Expert’s specifications for landslides in the central’s mountains and hills,” *VnExpress*, November second 2020).

Nevertheless, disaster communication is a complicated issue. During the disasters, particularly the rains and floods in the central region in 2020, while the causes and impacts require a certain amount of time for evaluations and accurate conclusions, the discernible effects led to the public’s feelings of insecurity and need for urgent solutions. While the authorities cannot fulfill these needs, a crisis of belief begins, and any attempts to rebuild trust after the disaster seem challenging. Impacts of environmental disasters cannot be restored even during a long period, which further increases the difficulties in communication.

We analyze the percentage of positive, negative, and neutral news stories in two online newspapers by defining what would be positive, negative, and neutral news on disaster communication (Fig. 4).

It is noticeable that neutral news took up the largest proportion (45%) with a total of 80 out of 171 articles related to the disastrous floods on *Tuổi Trẻ Online*. The number of negative articles (48/171) and positive articles (46/171) were similar, accounting for 28% and 27%, respectively. *Tuổi Trẻ Online* maintained a relatively neutral tone when writing and reporting about the floods in central Vietnam as well as the rescue efforts. Meanwhile, on *VnExpress*, with 85/184 articles about the disastrous, negative news made up the largest proportion of 46%. These negative articles were mainly centered around loss of human life and properties as well as confrontations to the government about the causes of the floods. Twenty-six percent of the articles were positive news which provided information about rescue activities. The remaining 28% were neutral news about warnings against the floods. When reporting about disasters, *VnExpress* has a concise way of presenting the information, which is quite professional. They constantly update data about the loss caused

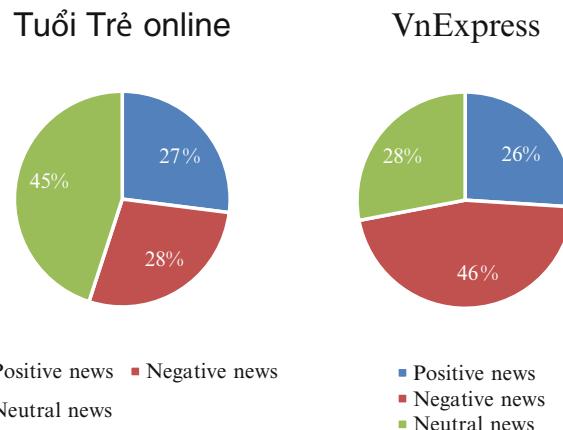

Fig. 4 Percentage of positive, negative, and neutral news on *VnExpress* and *Tuổi Trẻ Online* on disastrous flood in middle Vietnam 2020

by disasters – the topic readers are most concerned about, so this explains why this online newspaper receives the highest readership in Vietnam.

Communication about the rains and floods in the central area in 2020 gained a certain level of trust of residents in giving warnings and information about the weather phenomena and the damage to persons and property. Nonetheless, the public's trust decreased when they read about the rescue operations, aids, and cause analysis of this disaster. In the next part, we will analyze in more detail the public's trust during the disaster via the readers' comments in the newspapers.

Trust

The rain and flood events in central Vietnam in 2020 were a terrible disaster for its residents. From September 2020 to November 2020, the central area faced eight hurricanes in succession, two tropical depressions, and two constant periods of rains and floods starting from the sixth to 22nd of October 2020. The heavy rainfalls and flooding in the central region in 2020 are regarded as an extreme historic weather event, with the caution level of IV (disaster which causes serious damage to property, environment, persons, cattle, and poultry, which are too difficult to restore, which weaken the economic and financial conditions of multiple regions and provinces) according to the five-level scale for disaster risks in Vietnam. The rains and floods in the central region in 2020 were predicted by the hydrometeorological forecasting units. On September 13, 2020, the National Centre for Hydro-Meteorological Forecasting, Viet Nam Meteorological and Hydrological Administration, Ministry of Natural Resources and Environment, published hydro-meteorological evaluations for the year 2020, predicting that the central region is prone to extremely severe

floods. Thus, the government successfully built the public's trust in disaster forecasting.

During the disaster, the press provided diverse information about the conditions and duration of the disaster with rapidity, accuracy, and accessibility to target groups of the public. The information about the disaster remained one of the topics that drew the largest attention of the public, which was evident in the public's subscription to and interaction with the newspapers. We compiled statistics and noticed that there are a total of 2.774 readers' comments in 184 articles about the rain and floods in the central region on *VnExpress*. In addition to comments of grief and sympathy for the loss of the people in the central region, a large proportion of comments questioned the authorities' specifications for the constant rains and floods.

Particularly, when the Head of the Weather Forecasting Department, National Centre for Hydro-Meteorological Forecasting, indicated four causes for the heavy rain in the central, immediately 46 responses from the public skeptically questioned the lack of nonnatural causes such as deforestation and mass construction of hydropower dams blocking the flowing of rivers (Gia Chinh, "Why continuous rain and floods in the central?," *VnExpress*, October 15th 2020). Hence, the authorities' explanations could not truly convince the public.

Deputy Minister of Agriculture and Rural Development explained the causes of the rain and mass flooding in the central in an interview with *VnExpress*: "Large-scale hydropower lakes never discharge floods illegally, and the small-scale lakes are "not determinable"" (Tat Dinh, "Cannot determine whether small-scale hydropower lakes discharge floods illegally," *VnExpress*, October 20th, 2020). Fifty-eight comments from readers raised questions like: "Each lake has its measurement for floods discharging. If it is claimed that small-scale lakes are 'not determinable', then who supervises and takes responsibility for accidents?" and "Once it's a hydropower lake, it needs supervising?" The public probably had incomplete trust in the explanations of the authorities.

In the government's online newspaper, in the explanations for "Why the central faced heavy rain and continuous floods," only the weather patterns for heavy rain were mentioned as the cause of constant rain, whereas the central "fully stores water" "in the previous hurricanes and tropical depressions, resulting in predictable landslides and flash floods in the central" (Do Huong, *Government Electronic Newspaper*, October 16th 2020). Such explanations are not satisfactory to the public since they do not focus on the problem. It is, therefore, hardly possible to gain the trust of broad sections of the population through such statements. According to specifications of independent experts, Assoc. Prof. Vu Trong Hong, former Deputy Minister of Agriculture and Rural Development, President of Vietnam Water Resources Development Association, "Constant serious deforestation and degrading vegetation result in severe landslides when the central region faces flooding. 'Grief-stricken consequences of claiming forest resources'" (Thuy Linh – Vu Long, "Why disastrous floods, landslides occur constantly in the central," *Lao Dong Newspaper*, October 30th, 2020).

According to the statistics by the Forestry Administration, between 2016 and 2019, the area of damaged forest rose to 7.283 hectares, showing that Vietnam lost

2,430 hectares of forest annually. The major causes for the reduction of natural forest area are the shift in the use of land and overexploitation, especially in the coast of the central and Central Highlands. Deforestation has decreased vegetation in the drainage basins and the resistance to flowing floods, leading to rapid movement of floods. Besides, deforestation in the upstream areas is a result of logging, agricultural development, implementation of hydroelectric power plants, etc. All are responsible for the catastrophic floods and landslides in the central region. However, the causes provided by the government are only centered on climate change and the instability of the weather, so the public seem not persuaded.

Besides, experts are responsible for the public's skepticism. On October 30, 2020, Vietnam Digital Communication Association organized the forum "Small-scale hydropower plants and the flooding issue," in which the specialists presented conflicting ideas about the effects of small-scale hydropower plants on rains and floods. Specialist Nguyen Tai Son stated that small-scale hydropower plants did not cause floods to occur but reduced their number. Nonetheless, Dr. Nguyen Ngoc Chu refuted this idea. Dr. Chu asserted that small-scale hydropower plants could not contribute to the regulation of floods but increase their consequences: "The amount of discharged water is not greater than the natural flow, but the flowing speed increases, leading to more serious damage by flood waters" (Gia Chinh, "Controversy related to effects of small-scale hydropower plants on rain and floods," *VnExpress*, October 30th, 2020). In addition, he posited that the construction of multiple small-scale hydroelectric power plants possibly paralleled the exploitation of the natural forest. The article attracted the interest of a large proportion of the public, with 241 comments.

We analyzed 241 comments and found that 146 comments agreed that small-scale hydroelectric power plants increase the severity of floods, 46 comments refuted the possible effects of small-scale hydroelectric power plants on floods, and 59 comments proposed other specifications related to climate change, global warming, etc. (Fig. 5).

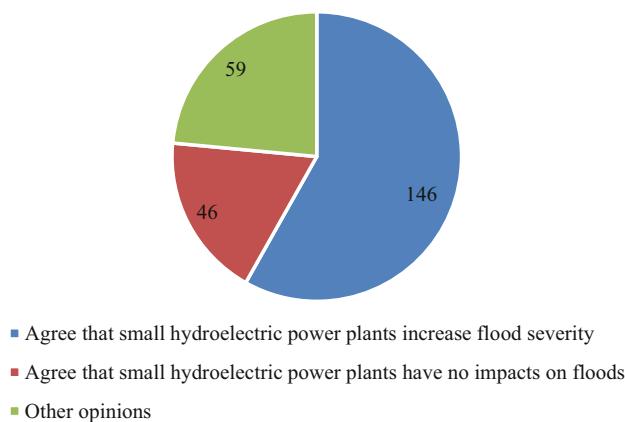

Fig. 5 The number of readers' comments about the impact of hydroelectric power plant on floods

A multitude of responses of the public showed a great concern: “Each expert proposes an idea conflicting with those of others, which brings about skepticism for people like me” (Mon), “Hope that after these storm and floods, the experts can provide guidelines for the future to relieve the suffering of people” (Uyen), etc.

In disaster communication, the key action is to build trust of the public. During a disaster, when people are terrified and disoriented, the guidance of the government, specialists, press, and communication units can contribute to orienting and building trust of the public. In conclusion, we will propose several principles for building trust of the public in disaster communication.

Conclusion

In this chapter, we have indicated a few disasters in Vietnam and analyzed disaster communication reflected on a specific case that is communication about the rains and floods in the central area in 2020 and the public’s trust. The public only gain trust in case of access to rapid, accurate information about the conditions, duration of the disaster, warnings, instructions to face the disaster in a detailed manner, and logical, direct explanations for the disaster’s causes. During the catastrophic rain and floods in the central region in 2020, the skepticism about the real causes of the disaster resulted in the public’s distrust. How can the government regain the public’s trust? We propose several measures.

First, independent specialists and civil and social organizations should be engaged in evaluating the impacts and damage of the disaster. When the public no longer trusts the government and governmental organizations, more trust is placed in independent experts and social organizations which are regarded as objective or supportive.

The *second* principle emphasizes statistical data and scientific statements. When the audience distrust the government, they maintain their trust in scientific data. Consequently, the provision of scientific data on the mass media in a manner understandable to the public can partially lift their skepticism.

The *third* principle revolves around the ability to control. The government’s ability to control manifests in determining the causes, effect size, solutions of restoration, and solutions of prevention in the future. The government is responsible for large-scale management; thus it is vitally important to have the public acknowledge that the initial statements are parts of a long-term plan to control disasters.

The *fourth* principle is cautiousness. If the public’s trust is lost, any action or statement is viewed in the angle of skepticism. Thus, the government should not necessarily make quick conclusions; instead, emphasis should be placed on evaluating the current status, which builds the public’s trust.

The *fifth* principle is responsibility. The public constantly ponders: who takes the responsibility? It is a must to hold an individual or organization accountable for inaccurate claims, not validated information. The public can easily lose trust but also willingly forgive if they are informed of the responsible individual or organization that apologize and propose solutions for the future. This is how trust can be restored.

Trust restoration proves a challenging issue that requires time; however, in case of utmost determination, the government can always find a solution.

Abstract

In the last one decade, social media has grown exponentially, invading geographical limitations, administrative boundaries, and even the apparent illiteracy of technology for aid. Meanwhile, this development has helped to veer off from the traditional trajectory of predominantly one-way line of communication in mainstream media, from a media-audience relationship to a media-actor/responder frame. Although there are various usages of social media before, during, and after a disaster such as early warning dissemination, preparedness guidelines, occurrence, aid requirements, and information shared in the immediate event become critical for effective response, often however resulting in a flood of information on social media, popularly referred to as “infodemic,” posing a major challenge in the decision-making process and overall management of disaster. Hence, there is a requirement of “social media policy” that places emphasis on the state-specific

P. Majumder (✉) · D. Dwivedi · G. Khera

mandates for the usage of social media during the time of disasters for acting as a catalyst in the decision-making process and enhancing the response mechanism during the time of disasters. This chapter tries to explore the current integration of social media in disaster management plans while exploring the current trends and challenges in the usage of social media for disaster response.

Keywords

Social media · Technology · Communication · Disaster · Governance

Introduction

A result of the multiple international and intercontinental conflicts and a continuous race for information, the accelerated technological advances and innovations are probably few of the positive outcomes from the turn of tumultuous situations. Until the last century, sharing of information or access to information in a shared time or concomitantly by more than one point of access became critical for conflict resolution and management. Internet emerged as a merger of multiple networks in the next few decades, primarily reserved for the military and gated academics. However, the need to *access* and *share information* modernized, and Internet slowly started evolving as a necessary additive in multiple uses. A product of the Internet, today, social media bypasses the dominance of traditional forms of communication media, including telephony, radio, television, paper mail, and print media. Instead, social media has expanded infinitely, through blogs, web feeds, and other forms of expression through the virtual communities and networks. Social media is often treated as a collaborative project, between multiple stakeholders. Micro-blogging websites such as Twitter have been lauded as one of the key tools to facilitate the organization of social congregations by serving as a stitching mechanism (Jeff Hemsley, 2018). Facebook, a social interaction platform where people from different walks of life converge, has also worked in tandem with people in different geographies.

Social Media as a Catalyst for Disaster Risk Governance

Disaster risk governance has evolved to be an entrepôt, critically placed between risk information and a processing system, wherein information is fed and then disseminated as decisions. These decisions affect how risks are perceived and how different agencies of change foresee impacts and act on them. According to the “Risk Governance Framework” of the International Risk Governance Council (IRGC, 2017), the processing system is none other than governance, which regulates how risk is appraised, and related concerns are analyzed and communicated, and management decisions are taken. It engages risk management through multiple actors and assigns rules, principles, and mechanisms to streamline decision-making. In a complex world where governance and its evolution may hold the key to disaster risk

reduction (Albris et al., 2020), social media provides a futuristic opportunity for polycentric decision-making and managing the impact of such decisions. Crowe (2012, 93) maintains that “the concept of how social media is impacting traditional response scenes, situational awareness, and public information...is merely the beginning of this conversation.” This is particularly due to the attributes of social media that allow for quick and cost-efficient methods of communication across the disaster management cycle rendering itself to multiple uses beyond the reaches of traditional emergency management. For example, research suggests that using convolutional neural networks (CNN) in geo-coded hyper-resolution images from social media platforms such as Twitter can extract flood depth information at a 65% success rate and monitor landscapes for urban flooding (Wang et al., 2018). Similarly, the emerging significance of citizen science has also pushed the “human sensor” factor into weather forecasting, where “in-field” assessment of hazard circumstances can result in “real-time” or live mapping of the actual occurrence (Rossi et al., 2018). A comparative analysis between human-rendered mapping and forecasted reach of hazard can expand on furthering the reach of social media into disaster reporting, response, and recovery. Social media has helped digitalize aid giving community network structures and improve relief to the last mile. In the instance of multiple collectives and groups working in tandem, questions on reliability of information can be a critical hit to giving and receiving help. In such cases, social media has aided to “cross-fertilize” information, wherein information is automatically screened as it is under scrutiny by multiple groups during or after disasters and is actively validated by ground-truthing (Mauroner & Heudorfer, 2016). Social media is a most viable channel of disaster mitigation through avoidance of loss. In a study spanning 496 households in the aftermath of the Bangkok floods (2011), it was discovered that social-media-enabled households reduced flood losses by an average of 37% (USD 3708 per household) (Allaire, 2016). Similarly, social media had positive and significant impacts on resilience-building behavior of farmers in Zanjan Province of Iran (Bathaiy et al., 2021). Additionally, considering countries with intensive agriculture such as in India, droughts, floods, and erratic weather patterns come as unwelcome obstacles to sustenance. Social media can be used by both central and regional governments to ensconce the value of social media in educating communities for improving coping capacity and resource planning as a G2C (government-to-citizens) communication tool. Social media adds on to governance as a vital tool as it performs the task of social cohesion, bringing together stakeholders for collective decision-making and an inclusive and integrated disaster risk governance.

Cases of Social Media Use During Disasters

Australian Bush Fires

Bush fires have blazed persistently in Australia for centuries. Regional government agencies, such as the Forest Fire Management Victoria (State of Victoria (Department of Environment), 2021), have tracked significant events, from the most recent

fire event in 2019–2020 to dated historical events such as the “Black Thursday” fire disaster in 1851. With multipronged losses spanning natural, economic, and cultural assets, lives, and trauma every year (Pitman et al., 2007), it is understood that the devastation in the country evolved to be chronic.

Throughout this timeline, modernization of communication technologies, in terms of cost and reliability, gave both the community and institutions space to improve action against the risk – deliver real-time to near-real-time information to at-risk populations, endorse collaborative field operations by the community and emergency managers, disseminate warnings, volunteer resource management, etc. In January 2013, when the Derwent Valley, Bicheno, and Forcett fires in Tasmania were ravaging through the homes, bush, and farmland, the community quickly picked up social media as an information dissemination channel alongside traditional information broadcasting devices. The “Tassie Fires – We Can Help(TFWCH)” Facebook page was initiated as an effort to organize the string of information and queries related to evacuation, shelter and refuge center, areal extent of fire, road closures, and largely requests for help (Irons et al., 2014). With a follower count of almost 21,000 within the first few days of creating the page, emergency services, such as the police, started sharing updates, charities, and donations opened up in a bid to assist in rescue and care. TFWCH also crowdsourced volunteer groups and utility workers to help local farms and industries recover in days’ time before the government support system could respond, thus avoiding substantial economic losses. The page was later developed independently into a social website on the Internet.

After the 2009 Black Saturday fires, Victoria woke up to widespread power outages, animal casualties, and land lost in February 2014 owing to fires from lightning strikes. In the 13 days, both emergency management organizations and people on the ground were galvanized into action, sharing around 7981 tweets through Twitter (Abedin & Babar, 2018). Users utilized “mention,” a tool commonly used in microblogging platforms, to attract the attention of emergency response institutions. Nearly 45% of the tweets by these institutions had been re-shared among the community for use.

Prior to the 2019–2020 bush fires, the New South Wales government released its State Emergency Plan(EMPLAN) and specified in its supporting plan the use of Facebook, Twitter, and Instagram as appropriate channels for broadcasting warnings and messages. During the fire season, the Australian Capital Territory (ACT) Emergency Services Agency posted 397 times. They shared graded warnings based on risk, updates on firefighting efforts on the ground, and also livestreamed media conferences on Facebook for remotely viewing users (Atkinson et al., 2021).

Kerala Floods

Kerala is the southernmost coastal state of India located at tip of the peninsula. In the year 2018, Kerala witnessed one of the deadliest disasters due to incessant rains, breakage of dams, and consequent massive flood. This was rare one in a hundred-year disaster which left that state in complete chaos as it was not prepared to

withstand such level of flooding. This event affected more than four million people, more than one million people were sheltered in relief camps, and around 500 people were killed. As per government data, 387 deaths were confirmed.

Communicating here became a challenge as phone lines were either busy or damaged. However social media platform with its wide reach to larger audience provided easy dissemination of information from victims. It enabled rescuers to attend to the people struck at unknown locations (Babu et al., 2019). This also ensured timely help is provided and any potentially fatal consequences could be averted. Further relief requests and needs were identified through group and individual posts and messages. Through which the necessary aid was arranged and distributed via volunteer networks united online. More importantly social media helped people stay connected and share about their whereabouts as well as well-being with family, friends, and acquaintances. The hashtags had significant role to play and were popularly used as #Keralaflood, #Keralafloodrelief, and #emdrf. Apart from this, people also shared general information such as on weather, road conditions, eyewitness photographs/videos, location status, do's and don't's, and even their emotions and sufferings. According to a research by Rekha Rani Varghese and Yadukrishnan T (Varghese & Yadukrishnan 2019), five social media websites had been frequented the most, viz., Facebook, YouTube, Twitter, Instagram, and WhatsApp. Out of these five, the most effective as per their study was WhatsApp followed by Facebook and Instagram. They also analyzed the time spent on these websites where they found that YouTube, WhatsApp, and Facebook were frequented for longer duration in the order mentioned. They also discovered that large number of people used Facebook Safety Check and few used Google person finder too.

COVID Response

During the spread of COVID-19, citizens who have access to social media platforms such as Twitter, Facebook, Instagram, TikTok, and WhatsApp as well that has a feature of sharing updates through status messages have played a vital role in impacting the actions of the community. A major part of the generation, specifically GenZ and millennials, used social media platforms during first wave of COVID-19, for not only sharing the insights on COVID-19 but also unverified claims of infection dense areas, symptoms, and rumors that resulted in uncontrollable virtual noise – resulting in widespread infodemic. To respond to such issues of infodemic, during the time of disasters, a mandate regarding the legal consequences of spreading rumors through social media platforms should be brought in place for keeping the disaster response process smooth.

From the first wave to the fatal second wave of Delta, the social media platforms were used for finding out the resources such as medicines, blood, hospital bed, oxygen cylinders, etc., as the second wave of Delta created a major pressure on the available resources. It was observed that the community strongly came forward as the *first responders* by using social media as a tool.

Challenges of Governing Social Media

Social media is a veritable tool of behavior and action. At the heart of the Web 2.0-based application lies the exchange of content between two or more users where they establish their identity, interest groups, and networks and initiate actions. What is thus most significant about this contraption is that it functions through the expression of intention, perception, and other back-end philosophies of the social media design. This *use* is also the biggest challenge to its sustainability in the disaster management domain. For example, during the 2011 East Japan earthquake and tsunami, platforms such as Twitter and Facebook became of unparalleled importance as people took to vital response and relief operations simply through the sharing of crisis information (Peary et al., 2012). Their communication on media, through community-based status reports, location-specific query building and resolving, and damage and injury counting, became streams of information in real time. In other words, social media aided in emergency management by letting people inadvertently take on the role of conscious and motivated risk information sensors (Resch, 2013). However, backed by a still-traditional perception of policy and action, most emergency management institutions on the other hand enforce hierarchical mode of operations through *commands, which are one-way directives*. This perspective limits quick multi-actor collaboration on the ground and leaves little space for people to become more than just beacons for *receiving help*. Although social media provides several typologies of information which can be segregated into thematic interventions throughout the crisis management cycle, the reluctance of the crisis management governing body to utilize them renders people on the other side unable to participate in recovery, rehabilitation, and restoration of their own communities.

Trust-building is a critical factor required for a successful collaboration through social media. An analysis of its usage in communicating risk during urban floods in Bandung City of Indonesia in 2018–2019 claimed that poor results could be attributed to a *lack of trust as to how social media could be used, or misused, or even be ineffective*. It was a visible impasse as the local emergency management body could not place trust in the citizens' intelligence and "authenticity." Meanwhile people also doubted the local authority's "willingness" to *take their queries placed through social media seriously and act promptly* (Mansyur et al., 2020).

Social media governance is a particularly tedious paradigm in itself as the prospect of accountability is difficult to be visualized at the policy-making stage and implemented on the ground during or after crisis situations. Since social media converts into streams of data flow, concerns such as regulation of privacy and ethical standards, presence or lack thereof of strategies to safeguard the objective of the emergency management governing body, priority management of crises, risk communication, and education and training of personnel among others take precedence immediately. Digital disparities, such as the lack of accessibility to Internet services, are made possible due to geographical limitations, and also complex socioeconomic causes such as illiteracy take away the opportunity to avert risks through social media. In such cases, the inability to deliver correct and effective risk

communication through social media lessens its purpose and likeliness to be utilized within the domain further.

Discussion and Glance at Policy

Social media policy for disaster risk management is required to address the following objectives:

- Avoiding a situation of infodemic
- Responding to disaster in an organized manner
- Ensuring authenticity of information
- Increasing the scale of outreach by receiving real-time information

Why We Need a Social Media Policy in India

Social media policy in India is required for *streamlining the activities of disaster risk management*. IEC (information, education, and communication) is a significant component of *disaster awareness*. All the IEC material consists of a major guideline that directs the individual to not spread rumors with reference to disasters. Due to the integration of social media in the process of disaster risk management, the problem of *infodemic* and rumors has increased, thereby creating major challenges in organized and smooth response during the time of disaster. Rumors during the time of disaster can not only hamper the process of disaster response but also lead to increase in the adversities during the time of disasters due to the creation of panic generation among community.

Safety Check feature by Facebook has been found useful during the time of disasters as Facebook community. During the dust storms of May 2018 in India, 10,000 people used the feature to mark themselves safe from the dust storms that claimed the life of people from Uttar Pradesh, Andhra Pradesh, West Bengal, and Delhi (<https://www.firstpost.com/tech/news-analysis/facebook-safety-check-feature-used-by-10000-people-to-mark-themselves-safe-during-dust-storms-in-india-4472679.html>). This highlights the significance of collaborative approaches in the process of disaster risk management. Disaster risk management is everyone's business. The integration of social media platform in the disaster risk management process by the government is essential considering the rapid sharing of information. Hence, social media policy for public-private collaborations in the workflow of disaster management is much required for government regulations.

State-specified common hashtags: During the time of disaster, the social media community use different hashtags for disaster communications. Hence, it is required that the "state" must come up with *common hashtags* that people must use during disasters, and it can be used by the government through the integration with geospatial and 4IR technology to generate the geospatial knowledge, which will ultimately help in providing the coordinated response.

Areas of Policy Intervention

- Agenda point 7 of Prime Minister's 10-point agenda on "Utilise the opportunities provided by social media and mobile technologies for disaster risk reduction."
- Transformation in *disaster response* is evident since the advent of social media. Social media acts as a catalyst in disaster response phase of disaster risk management through quick movement of information. Also, it acts as a platform for two-way communication, thereby enhancing the overall response process and mitigating the risk.
- Considering the relevance of social media and technology, it is significant to strategize the usage of social media in terms of a policy document that are legally binding for the purpose of avoiding ruckus due to the spread of rumor during disasters, thereby making the community/the user of social media and technology more responsible.
- A social media strategy/policy document should also contain framework of collaborative approaches as the collaborations and partnerships between government and industry will enhance the workflow/cycle of disaster management.
- Inclusion of usage of social media in disaster risk management plans.
- SOP for using social media platforms during different kind of disasters.
- Mandate for using specific hashtags during disasters as suggested by the National Disaster Management Authority or State Disaster Management Authority.

Conclusion

The root cause of the existence of social media lies in its ability to share information from one to manifold, with nominal to no burden of exuberant efforts or costs to the users. When applied to disaster risk governance, the tool has shown to proliferate but is limited by the actual treatment and response to it, whether by public administrations, emergency management organizations, communities, and individuals. The above-mentioned case studies of contemporary disaster situations and their turnout with respect to the use of social media help infer the urgent need to streamline its use and introduce implementation frameworks. They can be in the form of policies that guide an organized way to utilize the tool without the fear of virulent rumor-building, incorrect information transmission, and disparity among responders to disasters. Additionally, such policies will be more effective when designed as specific strategies, SOPs for execution, and built with clear rules of responsible action.

Abstract

The recent Covid-19 pandemic, which shocked the entire world by its spread and devastation, has changed the way brands sell and people buy. There has been a transformative change in how brands connect and communicate with the audience. The pandemic outbreak and subsequent lockdown coupled with the increased risk of health and hygiene made the brands rethink about their strategy and performance. During the pandemic, brand attitude and brand reputation gained greater relevance over brand positioning. Consumers not only evaluated the ways in which brands dealt with the pandemic but also shifted loyalty if their brands failed to act responsibly during the crisis. Brand communications evolved new ways to humanize their brand in order to make it more relatable to their consumers.

The crisis made the brands more focused on consumer experiences. Successful brands were quick to adapt, innovate, and ramp up experiences and safety measures for their consumers thereby enabling trust and promoting business recovery. Through various examples from India, this chapter attempts to analyze brand communication during the pandemic. It attempts to make an important

contribution to literature by providing evidence of the various strategies that some brands adopted at the time of disaster. By analyzing these strategies, this chapter attempts to guide brands in strengthening their communications and adding more meaning to their message.

Brand communication · Consumer behavior · COVID-19 · CSR

Introduction

COVID-19 emerged on the global map as a crisis that no marketer was prepared for. All countries faced the dual challenge of combating health crisis and dealing with dipping GDPs. The Chief of International Monetary Fund, Mr. Kristalina Geogieva compared the economic situation prevailing in 2020 to the period of Great Depression of the 1930s and pointed out that with about 170 countries witnessing negative GDP growth rates, this could be the year of worst global fallout. Pandemics have been a part of human history, however many global experts have termed this pandemic as a “Black Swan” event. The magnanimity of such epidemics might have varied over the years but they have always disrupted business, altered buying behaviors and greatly impacted marketing and branding strategies. There may be several factors responsible for this impact (Jonas, 2013):

- (i) Decreased consumption levels as customers choose to skip purchasing certain commodities and services purchased earlier.
- (ii) Higher indirect costs arising from lost labor and manufacturing.
- (iii) Offsetting and cascading impacts resulting from disrupted services like travel, etc.

Some of these changes are often temporary but many are permanent and have a lasting impact on the way business is conducted. Indian economy has suffered a major setback during the pandemic. The impact of the pandemic was seen across all sectors. The tourism, hospitality, and aviation industry that contributes around one tenth to Indian GDP was greatly impacted by the travel ban. The overall sectorial loss is expected to be around USD 16.7 billion, with direct and indirect job losses of close to 50 million (Grant Thornton – FICCI, 2020). Imposition of lockdown during the pandemic gave an initial boost to the Fast-moving consumer goods (FMCG) sector due to inflated panic buying demands of food, groceries, organic products, health, hygiene, and sanitizing products but the supply was soon disrupted by cumulative effects of lockdown, manufacturing protocols, supply chain disruptions, etc., leading to a flat growth in the sector. Remote working and travel restrictions surely proved beneficial for the telecom sector with increased demand of data and network. Business Standard, 2020 reported an estimated 1% increase in overall traffic and 20% increased viewership on OTT platforms. The closure of schools

and higher education institutions further created new opportunities for EdTech companies to bridge the gaps of online learning. Recent developments in business have forced the firms to reconsider their present and future marketing and branding strategies in order to maintain a constant revenue stream. Though most businesses ensured to convey their messages in tune with the global health emergency, they also anticipated future changes in market, more competition, and a requirement for innovative and aggressive marketing strategies. Most brands adopted business models that were conducive to short-term survival and long-term resilience and growth. While none of the brands were prepared for a disruptive event like COVID, most of them maintained the spirit of determination, supportive collaborative efforts, and used innovative communication strategies to engage the buyers.

Several researchers in the past have looked at the marketing activities during many forms of crises with a broader perspective. The shortage of supplies and services, rising costs, and change in buyer behavior leading to changes in profitability (Kotler, 1974), the ability of brand equity to mitigate product harm during crisis (Gao et al., 2015), marketing crisis, threatens marketing goals, reduces ability to control marketing environment and gives short response time (Clark, 1988) are some examples. In an attempt to arrive at a definition of marketing crisis, Clark T. (1988) pointed out that “Marketing crisis has more to do with how the marketers view the situation rather than how the situation actually is. In such a crisis scenario, marketing decision makers are a critical key to dealing with crisis.” However, there is little evidence of knowledge around marketing during pandemic, which offers an unexplored opportunity to study and document the marketing practices undertaken by brands during this time.

Brand Communication During Pandemic

Brands are intangible assets of a company that customers interact with. In most cases a brand is something that consumers need, value, associate, and communicate with. Brand communication is a powerful tool used by organizations to nurture relationships with its internal and external publics. Therefore, marketers put considerable effort in designing brand communications that contribute toward creating and maintaining positive attitude of the customers toward the brand. Brand communication has always played an important role in creating positive attitude toward the brand (Kempf & Smith, 1998). Research has shown that emotionally driven messages often create a positive brand attitude and brands, specifically in the Indian market, have always tried to touch the emotional chord of buyers through their messages. But during this pandemic, brands owners realized that it was time to use empathy and connectedness as main drivers of communication. Marketing communication by most brands focused on 4 Cs – Care, Compassion, Community, and Collective Action. Brand messages were creative and innovative, intertwining the lockdown experiences of the customers and convincing them in the most creative way on how their product or service was either the need of the hour or how the brand was concerned about their well-being. Communicating during the pandemic was like

walking on a tight rope for the brands as they had to continue communicating without sounding insensitive to the crisis. The message of social distancing was echoed by all prominent brands in their creative ads. The Indian dairy brand known for its creative ads reminded people to wash their hands, maintain social distancing, and stay indoors throughout the pandemic. In fact when Doordarshan re-broadcast the popular mythological shows Ramayana and Mahabhatta, one of the brand not only sponsored the show but, on demand of the customers, built up on the public nostalgia by running its old ads according to the dates when the show was originally broadcasted. According to marketing experts, this helped it gain a spotlight while other brands were struggling to make an impact in the midst of the pandemic.

Communication is an important socializing phenomenon and the power of communication in relationship building has been recognized by theorists in its various connotations. In marketing too communication plays a pivotal role in building brand awareness, brand recognition, and brand recall. As Kempf & Smith (1998) pointed out, brand communication is the most important component in maintaining customer interactions and cultivating positive brand attitudes like brand satisfaction and trust. Several studies in the past have also shown that consumers' brand satisfaction can be greatly influenced by direct brand communications. In most cases effective communication is used in combination with other marketing strategies by the brands to build long-term relationship with its buyers. This communication may be one way in which brands deliver messages through mass media to introduce a new product, create brand awareness, enhance brand visibility, and gain consumer attention. The primary goal of this communication is to influence purchase behavior of the customer favorably toward the brand. However, with the emergence of digital technology and proliferation of digital platforms, brand communication has become interactive and engaging. This has not only led to a massive change in demand and supply of products but has also made the exchange of information between brands and its consumers more dynamic and audience centric.

During a normal situation, most brands communicate to create brand awareness. Advertisements are placed across media to maximize the level of awareness, recognition, recall, and cognition (Voorveld & Noort, 2014). However, brand communication in a time of uncertainty, like the COVID, is very different, as it aims to build brand resilience and retain customer trust. In the midst of the uncertainty that grappled people during COVID, messages that breathed trust and support caught consumer attention. Brands aimed to garner trust by putting across transparent, meaningful, and simplistic messages. Most of the brand messages during the pandemic were seen performing either of the four functions – providing pandemic-related information, providing customer support, offering community help, or comforting and nurturing. While working toward forming the United Nations after the Second World War, Winston Churchill famously said, "Never let a good crisis go to waste." Similarly, brand communication during pandemic ranged from banal to opportunistic to exploitative (Aronczyk, 2020).

Most of the initial messaging undertaken by brands during first wave of COVID were focused around safety, hygiene, and social distancing. Some of the brands created distance in their logos while some others shared their own version of social

distancing through creative messaging. Some brands even used the opportunity to introduce new products based on social distancing themes. With hand washing being the primary guideline issued by all the health organizations, prominent soap brands in India launched hand washing challenge on social media to raise awareness about washing hands for 20 s as recommended by WHO. Apart from popularizing the habit of hand wash, the campaign garnered effective audience engagement resulting in billions of views online. Brands also garnered audience engagement by honoring COVID warriors, sharing their stories, and offering them discounts. A popular mango drink (name the brand) launched an Instagram Augmented Reality (AR) filter through which the users logging in though Instagram accounts could scan its logo to read about the inspiring story of a COVID hero. Another popular brand also launched a campaign under which it curated 100 stories from across the country about people who selflessly helped other people during pandemic and carried them on its liquid hand wash packs. On the packs, the company's logo was replaced with the image of the "Covid Protector" along with their story. It also launched a website to honor these COVID warriors.

Brands, advertising in India, realized that during crisis, messages need to be community-centric. India has a collectivist culture where physical and emotional closeness is important for individual well-being and the community acts as a safety net during crisis. Therefore, communication based on a community's reality has a better chance of being persuasive (Prabhakar, 2022). With the increasing complexities of pandemic seen in the second wave, brand communication joined the struggle for vaccination and oxygen supplies, supporting physical and mental well-being and addressing the issues of loneliness and COVID fatigue. Marketing budgets were curtailed to include CSR activities like supporting health facilities, creating vaccination awareness, increasing employee relief fund, distributing food supplies, and providing assistance to those who were affected. Brands employed affirmative storytelling, demonstrated purpose, and put a greater emphasis on consumers' personal challenges (Fig. 1).

Brand messages primarily went through various stages during the pandemic. With the first hit of COVID and the insecurities it brought along, brand communication mostly focused on health, cleanliness, social distancing, and consumer safety. Despite a growing number of people getting infected with the virus, brands continued to deliver messages of connectedness, solidarity, warmth, and reassurance. As companies came back in business, the messaging focused on consumer safety, contactless practices, home delivery, and adherence to the COVID protocols. Brands also promised better experiences, improved services, and prompt feedback to consumer concerns.

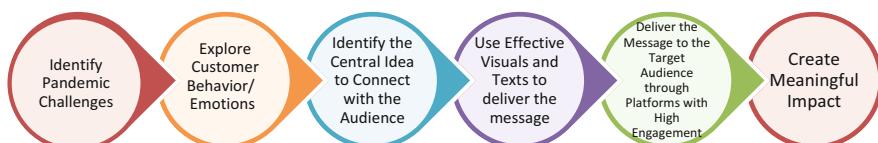

Fig. 1 Brand messaging strategy during COVID

Brand Collaborations During Pandemic

Pandemic made the marketers realize that collaborative working can help them sail through the storm collectively. “The basic aim of collaboration is to pursue goals collaboratively that otherwise would be difficult to pursue” (Di Benedetto et al., 2019). Pangakar (2007) found that when organizations engaged in alliances, it not only helped them to improve their chances of survival during global financial crisis but also helped them to reduce costs, boost production, and bring value to the customers.

This pandemic took the world by storm. It also revealed that there were stark differences among countries in terms of availability of infrastructure, information about the pandemic, and preparedness to deal with the crisis. The situation went out of hand even for the developed Western economies who found it difficult to provide necessary services to its various communities. The situation in developing economies was even worse owing to limited resources, infrastructure, and health facilities. Thus, most brands in collaboration with government and NGOs attempted to coevolve their practices and develop collective capacity to deal with the pandemic.

Major stress was on government and health sector as they were directly responsible for managing and controlling the pandemic. As quoted by New York Times (2020), pharma companies in the USA, China, and Germany shared knowledge and resources to develop antidote for combating COVID-19. Most countries focused on cooperation rather than competition and even relaxed laws to find medical solutions to the pandemic. Pharmacy giants collaborated to find vaccine for the deadly virus. The international financial, technological, and marketing expertise combined with research, development, and manufacturing capabilities of the country led to successful development and distribution of vaccines across India. These partnerships extended beyond vaccines as global pharma giant signed an agreement with Indian generic manufacturers for manufacturing Remdesivir, a drug that became a life savior against the deadly virus.

As lockdown prevailed and people were forced to work from remote locations, it led to sudden increase in demand for data. OTT platforms too became the popular entertainment arena for people locked inside their homes. An FMCG brand capitalized on the situation by teaming up with telecom company to provide up to 2 GB of data with the purchase of its products. The co-branding agreement was based on two important consumer insights: greater data use and individuals spending more time at home, which led to increased food and beverage consumption at home. The brand also collaborated with 20 brands from across the industry to launch a social media campaign that thanked several delivery partners and unsung heroes like truck drivers, delivery persons, farmers, etc., who worked tirelessly during the pandemic to bring happiness to millions of customers. The special branded packs carried custom messages aimed to thank respective brand and unsung heroes in a fun and quirky manner.

On similar lines 75 brands came together to launch a campaign with the aim to boost consumer confidence and give a head start to the jolted economy. The campaign urged the customers to help revive the economy through their purchases.

The campaign not only delivered a positive note about the collective efforts but led to increased online engagement from ten million consumers. Another remembered campaign in this category would be of a popular chocolate brand that used machine learning technology in its advertisement (name brand) to support several local businesses. The ad displayed names of local stores based on the location from where the ad was being watched.

Corporate Social Responsibility and Brands

Corporate Social Responsibility has always been an important determinant of company's perception in the mind of the people. CSR is the responsibility undertaken by the decision makers of the company to take actions that promote the welfare of society as a whole along with their own interests (Davis & Blomstrom, 1975). Huge amount of money is spent by companies in philanthropy, minority aid, and cause-related marketing (CRM) in order to improve their corporate image (Esen, 2013). Many consumers believe that even during the time of crisis, brands focus on profitability than consumer benefit but during this pandemic it was observed that most of the brands not only refrained from unethical practices but also proactively engaged in numerous CSR activities, especially those through which they could provide immediate help and assistance against the virus.

Socially responsible behavior became a major determinant for brand success during the pandemic. Research data shows that consumers switched brands during the pandemic if they felt that their preferred brand wasn't being socially relevant and responsible during the crisis. In a normal situation, it is very difficult for the brands to gain consumer attention and shift their purchase behavior, as their preference for specific brands is already established. However, the current volatile situation motivated buyers for brand substitution if it offered greater value proposition for the buyer. A report by Global Edelman Trust Barometer report, "Brands Amidst Crisis" found that 81% customers considered a brand's engagement in CSR activities as a major factor influencing their purchase from the brand during the pandemic. In the study, 65% customers also admitted that an organization's response to the pandemic crisis will be a major determinant of their future brand choices (Edelman, 2020). Consumers were also intolerant to brands that acted poorly in response to the uncertainties that arose during COVID. According to a March 2020 poll conducted in 12 worldwide markets by Statista, consumers from China and India were the most inclined to give unfavorable reviews of brands that performed poorly in the aftermath of the COVID-19 outbreak (Guttmann, 2020).

An American multinational entertainment and media company spent nearly \$27 million to support community initiatives across the globe during the pandemic. It also used its channel to provide people with timely information, engaging content along with extending its support to large-scale fundraising activities. Apart from providing masks to several countries, the company also managed disposal of used gowns, gloves, masks, and medical supplies. A cash contribution was also made by

its Indian counterpart to Project Mumbai for supplying urgent PPE kits to frontline workers in hospitals of Mumbai.

As stated in CSR report of a non-profit organization of an Indian multinational conglomerate, the company initiated several welfare schemes to benefit the community during the pandemic. Through its various schemes the company tried to extend support in providing food, medical grade oxygen, masks, vaccination, and employee benefits to the people during the pandemic. A prominent electronic company too donated oxygen concentrators, oxygen cylinders, and medical kits to the Government of Karnataka to support the initiatives to fight the pandemic. The oxygen concentrators were flown in internationally to reduce fatalities among the weaker segments of the society in the state of Karnataka. Several top blue chip companies of the country spent CSR funds to support health care initiatives of the government, while some also backed the digital learning and patient tracking software. PPP model was effectively implemented to combat the crisis as government units too supported extension of existing medical facilities through their CSR budgets.

Hospitality industry was the worst hit during the pandemic with curbs on travel, imposed lockdown, and the increasing threat of getting infected, but few prominent hotel chains remained in conversations by opening their doors to doctors and health workers during the emergency. Many hotels also offered quarantine facilities to mildly infected patients. Several travel websites started regularly updating the travelers about the status of COVID and the number of infected patients in the areas who wanted to travel soon after the first wave. Innovative models of corporate philanthropy greatly helped the country to fight the pandemic.

Digital Presence of Brands

India's presence in the digital space has increased considerably. As per the Digital India Report 2022, internet usage increased by 5.4% as 34 million new users joined in the year 2021–2022. Throughout the globe, technological advancements and expansion of cultural boundaries have led to increased use of social media as communication medium as well as a source for gathering information (Tam & Jeong-Nam, 2019). Customization, ease of access, and speed are making digital mediums becoming popular means of reaching out to customers (Dang, 2021). With the imposed lockdown it became the only means. The restrictions on traveling coupled with reduced physical contact further made social media the only resource to search for product information.

While businesses faced a downturn during the pandemic, digital media space became the only source available with the brands for remaining relevant and creating brand experiences. With lockdown imposed in most countries during the pandemic, it became important for the brands to offer digital shopping experiences to the buyers at their door step. Buying became “phygital.” Brands used engaging social media content to build new online communities and keep their brand name ticking in the public mind. As per a report by Mckinsey, the digital transformation has impacted in

such a way that India has already achieved such digital progress by 2020, which was not expected before 2024.

Overcoming the suspended video production facilities, brands successfully utilized user generated content to achieve greater audience engagement, improved reach, and higher return on investment (ROI) at a lower cost. A mobility service provider launched a campaign to promote hygienic traveling and safety precautions taken by drivers. The brand also asked the riders to share their traveling experiences through videos, which were shared on the company's page to build a shared view on safety. Similarly, food brands encouraged people to try new recipes and share it on their page. Sports brands asked customers to stay indoors and engage in various activities. One prominent sports brand delivered the message of staying fit while staying indoors through its campaign, which included videos of people working out in their homes. They also popularized fitness challenge using hash tags and initiated digital workout series named where athletes invited users to fitness challenges. It became quite popular with sports enthusiasts across the globe.

The pandemic also saw a steep rise in circulation of misinformation and fake news through online platforms. While a popular social media platform delivered the message of connecting to help each other during crisis, critics chastised it and other popular social media platforms for their inability to stop the spread of misinformation and fake products through their platforms.

Conclusion

The pandemic was a learning time for most brands as they had to take action relatively quicker than they would have in normal times to stay relevant, responsible, and remembered. Those who were slow on adapting to technology and collaborative working found themselves running short of the new challenges. Even after the return of normalcy, markets are operating in the phygital mode, giving equally rewarding physical and digital experiences to their customers. This crisis also shifted marketing from demand economy to trust economy, and brands realized that a little deviation from the expected lines of behavior during crisis could lead their customers to try alternate brands. Empathy, support, and solution remained keywords for brands as they tried to score best on the report card of their customers. The situation also saw some successful public-private partnerships and CSR initiatives that helped combat nuances of the crisis. Brands have learnt to deliver tailor-made communications and personalized products to their customers and this will remain a trend for future brand communications.

The current disruptions in the marketplace have made the customers even more demanding. Consumers want frictionless, anticipatory, relevant, and personalized experiences. Therefore, brands will have to use machine learning, data mining, and artificial intelligence in their operations to deliver the desired experiences to their customers. Brands will have to build resilience and empathy to compete in the market. The ways in which brands tackle the challenges put forth in the crisis

situation will influence their performance in the post crisis world providing greater opportunity, higher agility, and improved relationships with the buyers and suppliers.

Abstract

A major concern in disaster management is how to minimize damage to the society. In this endeavor, the prime focus has always been given to saving lives. However, in recent times issues associated with loss of property have emerged as another area of concern. During disaster, the most critical challenge before the disaster managers is how to sustain communication with the affected population and also with those who are likely to be impacted by it. Such a challenge generates the understanding that communication tools do have a significant role in managing disasters. Moreover, the above thinking conventionally has been found to be channelized through the traditional Media like Print media, Radio, and Television. Due to the faster changes in communication technology, we have now social media, which has emerged as an alternative communication tool for study among the scholars working on disaster research. Taking into account the above technological shift, this chapter focuses into how the Indian government

has used this tool in spreading information to connect with the affected population. How far it has been able to establish a sustained two-way communication within the governmental agencies and with citizens is an area that needs to be assessed. Does it bear the prospect of being a crisis management communication tool in addressing disaster-related issues? All these concerns have been elaborated with the core argument that the use of social media in managing disasters has opened up a new chapter toward digital democracy in disaster management practices.

Media · Communication · Disaster · Technology · Citizen and Government

Introduction

Over the past several decades, the frequent occurrence of natural disasters has significantly increased. This has caused in large scale, human injuries, deaths, and damage to property (Klomp, 2016). The loss associated with these disasters runs into billions of dollars, with thousands of deaths and injuries (Lu et al., 2016). This has imposed great challenges before the world community on how to address or manage the consequences of natural disasters (Klonner et al., 2016; Kryvasheyev et al., 2016). To reduce its impact, various management tasks, which include, mitigation, preparedness, response, and recovery, have given prior focus in most of the legal and governmental initiatives. In this process, communication tools have a substantive role. It has been acknowledged among the scholars that communication channels are crucial as they have the immediate responsibility to share information about disaster to the public. In fact, there has been a plethora of research work with regard to communication strategies during various disasters and the role of media. The focus of this chapter while admitting the role of media as a communication technology in disaster management practices is to discuss specifically the prospect of social media as an emerging tool in reaching out to a disparate set of publics. Social media is labeled as new media technology, which has opened a new chapter in communication technology, emerging as an alternative tool to manage disasters effectively. In this context, it is significant to learn about its prospect in creating an effective engagement among various government departments and citizens toward disaster management practices. Does this trend have any substantive association with the idea of digital democracy has been elaborated in the discussion section of the chapter.

The discussion section of the chapter is subdivided into three sections. The first section deals with an overall understanding on the relationship between media, disaster, and communication technology. This has been analyzed in the context of how communication technology is a critical determinant in shaping the relationship between media and disaster. The above aspect is elaborated with two significant trends. One, about information sharing, which primarily connects disaster with

media and the other trend is how media as a communication tool has received a specific attention under global conventions and also in various domestic legalizations and laws. This discussion is followed with a new shift in media communication technology popularly referred as social media that would form a part of the second section. It deals with the prospect of social media technology in setting a new trend in complementing the relationship between media and disaster. This will be analyzed through its capacity of wider reachability and accommodating multiple flow of information. Moreover, how this shift is visible in case of India would be the focus of the third section. It will present a narration on how Indian government has mobilized social media as a communication tool in its disaster management strategy. Finally, the chapter ends with the observation on how the application of social media technology has on the one hand opened up space for democratization in disaster management practices but on the other, it is not free from certain concerns. Gradually, concern appears to be visible over important issues like who is using this platform and the authenticity of information exchanged in this space. In this regard, it is argued that social media technology definitely has the prospect of circulation of information much faster in comparison to other legacy media including newspapers, radio, and television. A cautious approach is recommended to handle social media keeping in view the ethical and normative role of media.

Materials and Methods

This chapter is framed out of secondary sources of literature. As the focus of the chapter is to analyze the prospect of social media as a communication tool for crisis management, attempt has been made to provide a general understanding on it.

Media, Disaster, and Communication Technology

There is no dispute that in minimizing the impact of natural disasters, immediate effort has always been given to save lives. There has also been a significant decrease in casualties in many countries relating to disaster hazards. In this regard, credit goes to the advance communication technology system, which not only enables governments to detect the possibility of an impending disaster but also provides the pathway to disseminate information on disaster through early warning system. Such facilities, at least, become a critical factor in rescuing lives from catastrophes. In this attempt, the role of media is crucial as it acts as a channel to reach out to the masses. The definition of media has been contested, especially in the social media context where one finds a humongous amount of user generated content, which is accessed and also found credible as many empirical studies suggest. In the context of mass media definition, some analysts consider it as a medium of mass communication through which communication can be sent to large numbers of people. Such media include Radio, Television, newspapers, etc. Some scholars have used the term

media in the context of communication technologies along with the content transmitted by it, including the social media applications coming under the above context.

There are various ways to determine the relationship between media and disaster. The primary concern usually begins with how media covers issues of disasters. Here, the role of media is expected to be of a neutral entity, which is expected to be concerned with what is happening and how it has happened, sharing objective information. Under the above circumstances, a disaster is generally considered as an event and media as a communication medium that provides information to the public. In disaster management, information sharing is valued as a significant component in establishing the relationship between media and disaster. However, how media is communicating has always been a matter of much debate owing to various factors including the commercial interests, race for Television Rating Points (TRPs) and the breaking news syndrome to be one up in competition, bringing in unwarranted sensationalism in the disaster narrative.

If we take into account various global conventions, media is primarily referred as a medium of communication to generate public awareness and information sharing platform. In the Hyogo Framework for Action 2005–2015, communication has been given an important focus for raising public and institutional awareness. In its key activities, this framework has insisted on application of communication and space-based technologies along with dissemination of information. It has emphasized on engaging media to promote resilience and also to act as a stakeholder. Despite such priority, the Sendai framework for Disaster Risk Reduction 2015–2030 has identified the gap that there is a necessity to share information on disaster risk governance. In order to achieve the commitments of this framework, media has to be one of the key stakeholders in disseminating knowledge on disaster risk understanding where it could be utilized effectively as a channel of disaster communication at global and regional levels.

If we consider the role of United Nations Office for Disaster Risk Reduction (UNDRR), in 2013 it has established a network among journalists known as DIRAJ (Disaster Risk Reduction Network of African Journalists), which is a group of journalists who submit articles and cover disaster risk reduction problems in their local and national news networks. The network has evolved to include 50 African journalists who guarantee that news on catastrophe risk reduction would be widely reported in local and national media. The UNDRR will seek to expand the DIRAJ beyond Africa to Asia and the Americas in order to ensure that journalists communicate effectively on disaster risk reduction issues, not only to raise disaster risk reduction awareness but also to hold governments accountable for protecting citizens and public goods through the development of disaster risk reduction strategies. To empower journalists, a variety of journalism education tools are proposed to be provided. Investment will also be made in building and enhancing social media networks to support ongoing journalism networks.

Taking into account disaster as an emergency situation, the role of media has been viewed more broadly under this framework. Media has also to undertake a responsible and inclusive role on its way of reporting and communicating strategy. The most significant aspect is that both traditional and new media along with the

communication technology as a whole have received prime attention under this global commitment. It has also specified the role of media, whatever its form, to portray its role as a communicator in disseminating accurate and nonsensitive disaster risk, hazard information. In this process, it needs to represent disaster-related information in a simple, transparent, easy-to-understand, and accessible manner. Further, they have to also adopt specific disaster risk reduction communications policies in cooperation with the national governments. It could be argued over here that media as a communication technology needs to educate and create awareness among people in accordance with the national practices.

Such an expectation from the news media in disaster communication, however, is not free from criticism on the way it communicates. Concern has been persisting among the critics that media could also spread wrong information. It could also promote myths that might affect the recovery process (Monahan & Ettinger, 2017. p. 479). The above anticipation also needs to be discussed in the case of new media technologies and social media being one among them. In fact, the conceptualization of media as a communication technology has got more attention in the globalizing environment. Such a shift has broken the conventional way of communication where media continued to be the sole source of information to the general public at large. Its arrival has invited the space for dynamism in the communication system that motivates this chapter to look at its prospect.

Prospect of Social Media

One can find a number of writings on the potential of social media as a revolution in communication technology in present times. Social media consists of a group of social networking applications, the most popular among them being Flickr, Face book, Twitter, and You Tube. The applications of these social media platforms runs through the internet. While defining what constitutes social media, Palen et al. (2009) write, “These apps are supporting high social engagement and user-content development typically at a one-to-many or a many-to-many scale.”

Most social networking platforms work on a variety of devices, including smartphones, desktops, and tablets, which have the ability to act as a communication tool for cyber informatics knowledge system. In the case of natural disasters, social media has been used to “increase situational awareness and improve emergency response” (Steiger et al., 2015). It is claimed that in disasters, social media activity has gained attention in the year 2007. In order to discuss its prospects, two themes have been identified, viz., reachability and multiple channels of communication.

Reachability

Social media has got both technical and popular recognition that it has the potential to solicit varieties of information by using the public as information source (Latonero & Shklovski, 2011). It is distinguished from the traditional media on the basis of its

reachability. The later form of media is only confined to the place of its performance. Social media has no such limitations. Chan identified five features of social media, including *connectivity, collectivity, completeness, clarity, and collaboration*. All these features indicate that it has a wider reach and access. In the context of disaster management, government agencies are now opting for social media platform to alert communities and to disseminate situational pronouncements that are authoritative. From an organizational standpoint, disaster response agencies may use social media to engage with the public and perhaps seek ground information in catastrophe circumstances. It not only generates massive volumes of data, but also varieties of data types like text, images, and videos. If we look at the pattern of users of social media, it is a platform that can be used or accessed by government agencies and also by other agencies including citizens. There are 3.96 billion total social media users across all platforms as of January 2022 (source?). Every month, an average individual switches between seven different social media platforms. Adults now spend more time on social media than ever before, averaging 95 min each day across all platforms. Despite the doom and gloom, Facebook remains the most popular marketing platform on the planet (93%). Instagram is ranked second (78%). In 2020, Facebook will account for a quarter of all digital ad expenditure (25%), compared to Google (28.9%), Amazon (10.3%), and others (35.6%). Over the course of 2022, Facebook Messenger is expected to reach a staggering 3 billion users. The above database indicates that the use of social media is gradually expanding. It provides the user a unique opportunity to share critical information on large-scale spatiotemporal data to emergency managers (Granell & Ostermann, 2016).

In general, disasters are marked by a strong demand for information. Such requirement counters complexity when there is less scope with the dissemination and for information accessibility (Shklovski et al., 2010). It is quite obvious to consider social media as a supplementary datamine for handling emergencies. In this process, certain features of social media messaging enhance its prospect of reachability, like Volunteered Geographic Information (VGI) to show geographic reference (Goodchild, 2007; Sui & Goodchild, 2011). Rather than pushing information to residents, the aforementioned technology allows emergency responders and policymakers to extract social media data to monitor shifting events in disaster areas.

People, in general, serve as sensors in disaster zones, providing real-time, geo-referenced information to complement crisis information provided by expert sources (de Longueville et al., 2010a, b). It could also be a very effective communication mechanism in all the phases of a disaster. It plays an important role in all stages of a disaster, viz., pre-, current, and post disaster (Houston et al., 2014). In recent years, social media has progressed from being a passive information outlet (i.e., disseminating static disaster preparedness information) to an emergency management tool capable of disseminating real-time warning information, receiving requests for assistance, and establishing situational awareness based on user activities (Lindsay, 2011). It can also be utilized to boost the social capacity of information generation and dissemination through peer-to-peer backchannel interactions. Schnebele and Cervone (2013) showed how volunteered geographic information (VGI) from social media sources may be integrated with remote sensing images and

digital elevation models to create flood hazard maps in their research. Even a small amount of VGI can dramatically improve the quality of hazard mapping. The coded data may be analyzed over time and space to offer real-time situational awareness of occurrences. Liu et al. (2008) have illustrated how the activity of disaster-specific Flickr groups may be tracked over time to document disaster impact, response, and recovery activities. The Automated Web Text Mining (ESA-AWTM) system, developed by the Australian government, analyzes Twitter interactions and offers near-real-time event identification, warning, and monitoring (Cameron et al., 2012). The “Tweet Tracker” program for disaster assistance helps to track, analyze, and monitor tweets. This application can distinguish between geo-referenced and non-geo-referenced tweets, do keyword searches, and generate and show trends for user-specified keywords introduced by Kumar et al. (2011). In near-real-time, information derived from social media data can assist policymakers in understanding the big picture of the emergency scenario.

Multiple Channels of Communication

Social media as a communication technology has offered the scope for multiple channels of communication. It enables both sender and receiver to interact and communicate with each other on various issues. Such a feature often attracts the attention of scholars to view it as a tool to promote democratic tendencies in the digital sphere. It is also argued that social media contains the potential to establish and build communities online. It has the ability to connect people through various formats and platforms where they could share information and also their ideas. Even, it can encourage debate and mobilize action (Price, 2013). Such changes have opened up the trend of participation where the end user could communicate with the source.

Disasters provide a unique opportunity to investigate how the idea of time might challenge established communication trust paradigms. Indeed, following the earthquakes in Chile, a recent study found that catastrophes provided a chance for communities to improve interpersonal trust (Dussaillant & Guzmán, 2014). By examining the verification of information during catastrophes using a guardianship of trust model, this method expands on previous work that categorizes the functioning of social media (Jung & Moro, 2014; Houston et al., 2014). The importance of geographical information in social media data for disaster management was discussed in the preceding section. Disaster mapping is a crucial tool for disaster management to understand what is going on. The factors that govern and ensure trust and influence power in connections between individuals and emergency services organizations are highlighted in this approach.

It has long been recognized that geographical data from social media may be utilized in catastrophe mapping to help disaster managers to better detect dangers and estimate losses (Huang & Xiao, 2015, Kryvasheyeu et al., 2016). In addition to the above, it is to be noted that this platform also provides opportunity to share their experience through exchange of ideas and opinion through the features like blogs. It

has been acknowledged in the Sendai Framework that focus must be given to 360-degree communication and advocacy campaigns, which would include the role of media and especially the various social media platforms and applications. This task opens up the scope for interaction among disaster practitioners, government, and nongovernment organizations and the users and the population as a whole. In this regard, a feature like “blog” has a huge potential to connect with multiple users.

If we consider the Indian government’s initiative, the above prospect of social media is also found to be visible in disaster management practices. Indian government has come up with a central Act of Disaster management in the year 2005. Under this Act, government is committed to raise public awareness and take necessary step toward sharing relevant information on disaster. Such a commitment has materialized further, given the public information campaigns launched by the government from time to time. In this activity, the role of both the traditional and new media was apparent. In 2016, the Indian government initiated the step toward opening up social media profiles of officials at the National Disaster Management Authority (NDMA). This was followed up with the creation of Information, Education and Communication (IEC) cell within the NDMA according to the data published by Govt. of India on its NDMA website. The NDMA also has its Twitter handle, which is followed by almost 2.4 lakh people. NDMA also runs its own blog, which is regularly updated. It encourages the officials and disaster management practitioners to contribute their viewpoints on several themes on crisis management. Along with the above, the other applications like You Tube and audio-visual materials are also used to generate awareness on how to respond to disasters.

Conclusion

The foremost challenge before media as a communication tool is, how it covers disaster events. Concerns persist that media could glorify myths and also disseminate false information. Acts, such as these may lead to reactionary behavior, bringing challenges for response and recovery aspects. The above anticipation in the case of social media also could not be escaped. One finds a huge amount of fake news, rumor mongering, and hate narrative on various social media platforms, which many a times comes from anonymous sources. There is no dispute that as a communication technology, social media has grown in popularity as a viable avenue for expanding disaster management’s horizons, but the socioeconomic imbalance in the utilization of social media data should make us wary of using these technologies for such reasons. Social media is also not free from the continuity of digital divide concerns where gaps persists among those who have access to information and communication technology and the others who do not have (van Dijk, 2006). Certain socioeconomic groups, such as those with little money, lack of education, and the elderly, may lack the means and abilities to use social media and thus get excluded from the information exchange via social media in critical times. Concerns also persist with regard to the generation of situational information. It completely depends upon the

knowledge and intent of the user on what and how to share information. Depending on whether users are aware of how their social media information is being used, this type of information might be active or passive. Some scholars have raised concern on the way situational information is extracted. Using social media for disaster management is a difficult process, and there is no one “silver bullet” answer in this relatively young and developing industry (Croitoru et al., 2013). The dissemination of official statements and situational updates to the community is one of the most critical duties in natural disaster management. This requires disaster managers to have a better knowledge on the social network structure in which disaster-related information could be disseminated or exchanged. The advent of internet networks has opened up new avenues for research on the information sharing behaviors of diverse actors (e.g., regular users, authoritative agencies, and news media) during natural disasters. Many investigations have indicated that these networks have a hierarchical structure. Cheong and Cheong (2011) conducted a social network analysis of tweets related to the 2011 Australian floods and discovered that “local authorities, political personalities, social media volunteers, traditional media reporters, and people from not-for-profit, humanitarian, and community associations” were the most prominent users in disseminating disaster-related information. According to some scholars (Kogan et al., 2015), the most essential nodes in disseminating helpful information during the 2012 Hurricane Sandy crisis were the local government officials and the media. However, the tendency of democratization invites for an active role on the part of the general users who could effectively contribute their experience and knowledge through this communication technology.

Despite that social media offer a lot of promise for enhancing risk communication and catastrophe information distribution, there are some issues about the quality of information gathered from social media data (Goodchild & Glennon, 2010; Goodchild & Li, 2012). In case of Tohoku earthquake and Tsunami (2011), it was reported that long after the victims had been rescued, the flood of pleas for help persisted (Lindsay, 2011). Finally, the chapter concludes with the observation that there is an expansive prospect of social media as a communication technology as it enables the mechanism of an overall communication network where user could play the role of sender and receiver of messages, information, and ideas. Its efficacy in serving the broader purpose of media needs to be investigated further.

Abstract

It is not unusual to hear common discussions about creating or strengthening or re-establishing strong social links, especially communication networks, in the context of aging people and disasters. Research studies believe that informal networks and professional interventions in community care for the elderly exist. However, the larger pertinent question remains unanswered: What are the unique challenges the elderly face regarding effective communication during crises. Older adults are often more vulnerable during disasters because of age-related changes and chronic situations. Over the past decade, the use of social media has increased even among the elderly population. While several organizations and communities have used social media as an effective platform to communicate news and other relevant information about disasters among the public, very little is known about how aging people use social media to plan, implement, and recover from disasters or any other matter such similar crises. Hence, through a narrative analysis of substantive data from the field, this chapter attempts to understand the significance of social media as an operative communication source for aging people during disasters. This study aims to map the fears and apprehensions older adults have during disasters by examining their experiences. It is

School of Communications, XIM University, Bhubaneswar, Odisha, India

essential to study the various aspects (both physiological and psychological) of a crisis in the context of older adults and the possible ways of coping with the help of social media engagement. The central argument of this chapter is that social media can be utilized as a communication resource by older adults during a crisis. This chapter conceptualizes a range of recent available literature using an inductive methodology. This chapter would emphasize the current global Covid-19 pandemic situation. It would collect data through in-depth interviews and case study methods from a selective sample of respondents (aged above 60 years). The universe of the study is Kolkata, West Bengal.

Keywords

Social media · Communication · Older adults · Disaster · Community care

Introduction

There have been two significant substantial consequences of the Covid-19 pandemic on older adults and their use of information communication technology. First, their Internet usage has increased throughout the epidemic, although many have experienced isolation, loneliness, and reduced mobility. As a result, they have turned to their phones and the Internet for assistance. The second point is that, before the epidemic, older adults were less active in smartphone usage than younger generations. Interestingly, this generation's use of the Internet has risen much more. That is why a new digital divide is forming among the digitally lagging older people. Covid-19 pandemic has resulted in a phase of devastating and continuous crisis that was depicted through social media and its engaged audiences. The pandemic witnessed a time of innovative developments among several social media outlets, and the question here is to see whether such innovations were inclusive of older adults or not. This brings us to a recommendation that possibly a reliable mobile network combined with learning digital skills is vital for older adults to take advantage of developing technological solutions, many of which will improve their quality of life. It has to be noted that in the longer run, falling behind on digital or Internet skills might have adverse effects on the elderly. Technological intervention in communication and social networking among older adults has been well explored in a study where older adults have been found to depend on new media in their daily lives (Dhar, 2018).

Conventionally, social networks could be defined as a network or link consisting of those with whom we have ongoing relationships (Berkman et al., 2012). Through such networks, individuals are linked into smaller groups and the larger society. However, the advent of new information technology provides a new dimension to this traditional definition by making the concept of networking vast and immediate. The idea of a network emphasizes relationships between people rather than groups or institutions; it is a particularly suitable tool in the search for understanding of the social aging process where relationships are central.

The unrestrained spread of Covid-19 has called for unprecedented measures, to the extent that the government had to impose lockdown and quarantine norms in the nation. Aging can be described in many ways. For instance, it can be used to study and reflect upon the profound processes of social change that aging brings with it. One of the central arguments of this chapter is that it emphasizes the point that signs of aging are not only about the more significant concern of how to provide care to the elderly as the world undergoes a dramatic generational transformation. It is more intense, and beliefs and practices associated with aging throw light on the much broader social-cultural phenomena, i.e., the connection between individuals, families, and states. Interestingly, aging people's perspectives are much more multifaceted and, simultaneously, nuanced, just like a media discourse. In examining aging in these ways, this chapter builds on several frames of earlier work, questioning and contributing to the ways we broadly study and theorize modernism, innovation, social change, and aging and, of course, social and cultural life and the subsequent changes because of the pandemic globally.

This chapter will be divided into two segments – in the first part, it will be discussed how older adults are suffering in different ways, especially during Covid-19, and how they are currently dealing with these struggles. The second part will focus on the interests of older adults in other emerging technology solutions that would further improve their quality of life. And, more significantly, how these solutions can be best implemented for the older adults to adopt them. This study explores how the so-called “young-old elderly” – who still have relatively good health and are still mobile – used the Internet before and during the crisis. The study also maps their expectations and fears of getting older and discovers their interests in different tech solutions that solve emergency issues. For the narrative review, an extensive search has been done for secondary data like research papers, recommendations, and documents from different national and international organizations associated with aging people from March 2020 to March 2022 (though not limited to). An exhaustive search of data has been done from all possible resources. Though the impact of Covid-19 is notable among older people, the effects of the Covid-19 pandemic on the mental health of aging people have not yet been done broadly in the Indian context.

Literature Review

Age-related discrimination has been apparent in the existing literature and media reports. Images of older people being reduced to bodily parts and portraying the unfavorable preconceptions of older people as depressed, lonely, abandoned, or defenseless have been utilized often in the media and popular culture. Additionally, the discourse on intergenerational conflict brought on by the epidemic and pitting generations against one another (younger people's perceptions of older people as a burden, etc.) leads to higher rates of abuse, marginalization, and stigmatization of the elderly. It has become more critical, especially when the world is under a Covid-19 pandemic. Studies show how with the increasing rate of coronavirus disease in 2019,

aging people faced excessively hostile effects, including complications, concerns about disturbances in their daily schedules, and caregiving access. They also faced difficulty adapting to technologies and were concerned that loneliness would only deepen prevailing mental health conditions.

Several studies have stated the shielding effects of social involvement and gathering on the mental well-being of older adults and its positive impact on cognitive functions (Douglas et al., 2017; Loyola et al., 2018). There has been a significant transformation around the world from the traditional joint family to individuals, and then the involvement of the market, and the state, as the critical positions of aging care. Such changes in modes of aging involve quite notable alterations in considerations of the human condition. The substantive data (ethnography) collected from the field in Kolkata suggests that the widespread belief presently is that majority of the older adults among the middle and upper-middle classes have their children settled abroad, which has resulted in these aged persons organizing life in different novel ways.

Older adults are more vulnerable comparatively during disasters and similar situations. For them, receiving and understanding emergency warning signals and taking appropriate measures might be difficult due to declining physical, sensory, and cognitive capacities. In recent years, it has been shown that the use of social media has expanded considerably. Social media platforms have altered the way individuals meet, communicate, and interact in a computer-mediated world. In disaster response, social media platforms are becoming increasingly important, as noted in several studies (Cohen, 2013; Sarcevic et al., 2012). So, it shifts the entire argument toward the usage and cognitive capacity of using social media tools during disasters and emergencies by older adults. As reported by a study by Cohen (2013), social media tools were initially utilized by the general public to communicate and are gradually being adopted by emergency responders.

The pandemic has caused sudden shifts in the lifestyle of aging people. The destructive effect of isolation among elderly people has been well documented (Vahia et al., 2020a). We have spoken to a few elderly people in Kolkata for this study. The respondents were a part of the more extensive doctoral study on media and gerontology undertaken in 2012–2017 in Kolkata, West Bengal. The secondary data suggests a much more nuanced picture. Approximately 1 year into the pandemic, several studies have shown that older adults may be less negatively affected by mental health outcomes (Lei et al., 2020; Douglas et al., 2017). It is interesting to note that the longer-term effects of Covid-19 remain unclear. Mobility for the elderly outside their houses is crucial in physical exercise and continuing with daily activities like buying groceries, socializing, and visiting doctors.

“Disasters are characterized as a condition in which the social fabric is ruptured and becomes dysfunctional to varying degrees, resulting in maximum community upheaval and displacement” (Britton, 1988; Fritz, 1961). We need to accept that not only are the physical actions affected during pandemic protocols but also emotional well-being. Several studies have defined mental well-being consequences of quarantines like higher risk of depression, stress, emotional disorder, irritability, and lack of sleep as signs associated with higher rates of emotional vulnerability in elderly

people (Huang & Zhao, 2020; Mazza et al., 2020). Elderly people tend to have lesser reactivity capacity to stress than younger adults. Still, given the magnitude of the Covid-19 epidemic, there was a larger concern about the global cognitive well-being crisis among older adults (Ostacoli et al., 2020). It is quite possible to trace the legal discourse around elderly care in India to the international “gerontological” discourses that somehow totally ignore the needs of aging people in diverse socio-cultural locations. The UN Department for Social Affairs (DESA) published a policy paper on Covid-19 and senior citizens in April 2020. This outlines the problems faced by older people across the world “older persons are frequently overlooked in development and humanitarian strategies and their funding. Considering the higher risks confronted by older persons in the Covid-19 pandemic, development and humanitarian strategies must explicitly identify and consider their needs, challenges, and strengths at all levels and in all settings.” (<https://www.un.org/development/desa/ageing/news/2020/04/issue-brief-on-olderpersons-and-covid-19-a-defining-moment-for-informed-inclusive-and-targetedresponse/>)

Responding to Common Needs and Problems of the Elderly

The Covid-19 pandemic has had a significant impact on older adults, not only in terms of the number of deaths but also in terms of the physical, social, and emotional effects of the physiological and psychological requirements: shielding, physical isolation, and social distancing. Then again, the impact on homebound elderly residents because of the pandemic measures implemented by the governments across the globe added with a reduction in local home care services had been profound. Furthermore, many elderly people avoided getting medical help as their anxiety and panic intensified, potentially resulting in increased health issues. Moreover, many were also found to be in complete isolation during the whole period of the pandemic. In the course of research on present-day networked society and the situations of the elderly before and during the covid 19 pandemic, it became clear that the distribution of networks, if extended to all possible sectors of physical and psychological wellbeing, could prove to be beneficial for the aged. The concept is that older people must remain valued as a resource for their families, their communities, and society as they were before the pandemic.

The Covid-19 pandemic situation has been difficult in all aspects. The older adults being more exposed to medical complications face the emotional repercussion of social isolation, feeling of liability, and restricted freedom. Moreover, besides the physical and psychological problems, there are challenges to using technology as that had become the only communication mode during the pandemic. So, older adults are in a position of excess grief, loss, and financial constraints. All of these make them more vulnerable to higher rates of psychiatric problems. As the pandemic broke out, it was evident that elderly people were at risk health-wise. It is to be understood that both natural and conflict-related disasters tend to pose grave threats to human safety, health, and well-being: other than direct deaths, increased risk of disease, damaged social services, disrupted livelihoods, and displaced homes. This

also shows that the ratio of more emergencies is directly related to the security concerns of older people. Nonetheless, the fact that older adults comprise a more significant part of the population, which is more vulnerable during emergencies, does not imply that they are weak in general, as many of them continue to function fine and remain wholly involved and engaged in the daily lives. Interestingly, older people are considered resources in their immediate and more extensive networks, predominantly during emergencies and crises. Their extensive long experience can make them models of personal resilience, motivation sources, and applied knowledge. They can give voluntary aid, care for family, participate in recovery initiatives, and support causes.

Aging often brings difficulties preventing the elderly from living independently and accessing services. The first question that the existing literature in the related area of aging poses is that is elderly abuse and discrimination gendered. This is another dimension to be explored in the larger argument. There is an urgent need for better data gathering and disaggregation for addressing age-related discrimination. The state of elderly women is highlighted in one of the UN reports, “In 2050, women will comprise 54 percent of the global population aged 65 years and over, and 59 percent of the total population aged 80 years and over. Women experience greater economic hardship as they age, owing to a lifetime of gender-based discrimination, particularly in education and employment, ending up with few savings and assets. They are also denied rights owing to the intersection of ageism, widowhood, disability, invisibility and negative attitudes about their value and capabilities.” (https://sustainabledevelopment.un.org/content/documents/26120MGoS_discussion_paper.pdf pp14–15). Older people are often marginalized and subjected to various social and cultural problems besides economic difficulties. “A study by Pew Research Center published in January 2019 found that people older than 65 years were more likely to share fake news in the US. It’s not hard to imagine a similar situation in India —more than 200 million WhatsApp users are in India. In addition, WhatsApp is ubiquitous and is often the primary source of new information, especially news. So, getting fake or false news becomes another source of depression among the elderly” (Chaudhary & Suresh, 2020). Older people are less familiar with technology and applications and face the highest risk of falling prey to disinformation and misinformation about any topic possible under the sky. Hence, it could be stated here that access to information is another challenge. In addition, data on elderly violence have persistently excluded older persons living in low- and middle-income nations, despite some evidence to the contrary. The media has extensively covered instances of Covid-19-related elder abuse and neglect. Older adults are more likely to experience domestic violence, such as physical, psychological, financial, and sexual abuse, while physical distance orders are being enforced.

The study by Chaudhary and Suresh (2020) further notes that “loneliness is a serious concern among the elderly, and could be a result of lower economic resources, death of contemporaries or spouse, lack of an active social life and dissatisfaction with familial and social relationships.” Additionally, older persons

are more likely to live alone, which increases their vulnerability to some of the adverse effects of loneliness on their mental health. Social distancing and quarantine procedures, which may make it difficult for people to acquire food and income, especially if they live alone, have worsened such risks. Even before the pandemic, older women's considerable unpaid caregiving responsibilities and the discrimination they have faced their entire lives might impact their health, happiness, probability of developing a disability, and access to healthcare in old age. The Covid-19 epidemic has substantially affected older persons in many countries worldwide. The government declares the physical, social, and emotional effects of the specific requirements, such as shielding, physical isolation, and social distancing (Sclater, 2020). The quarantine inferred a fundamental change in the existence of aging people, including a reduction in social interaction or participation in any gathering. These changes have adversely affected their mental well-being (Vahia et al., 2020a, b). To summarize all the studies in this review, it can be said that risk factors and vulnerability because of social isolation in aging people are much higher and needs to be appropriately addressed for practical solutions.

Excerpts from Case Studies

This chapter, with selective case studies on aged people and their experiences of communication through social media, tried to determine the role of social media in crisis response, preparedness, and recovery. The purpose of case studies is to explore what it means for aged people to socialize in crisis or disaster situations through social media and how helpful it has been in dealing with the pandemic situation imposed by Covid-19. Social media provides them with a much broader and more interactive environment. For an aged person, the influence of the Internet and new media technology on the daily social lives coincides with the time probably of withdrawal from the workforce market, becoming a grandparent, experiences of losing spouse, friends, relatives, and loss of health and mobility. Social networking sites, blogs, and mobile platforms mediate the present-day relationships with family members, friends, and broader social networks, especially during the pandemic. This factor relates to how social media can be integrated and used in the lives of older adults. From the older people's experiences, it is evident that the older generation used social media tools to overcome the vulnerabilities imposed by the Covid-19 pandemic. Besides socializing, older adults think that information and education related to financial and health issues are another significant draw for them. The Internet has become more of a need to them. From depression and diabetes to dementia, the elders can get and give support and information within the comfort and convenience of their homes.

1. *One female respondent of 65 years of age recounted how she started exploring the possibilities of new media when her only son decided to shift to Germany a few years back, around 2009. She studied it thoroughly with the help of relatives*

and other family members. She emphasizes that learning to use social media has been one of the boons in her life, which she realized in the Covid-19 scenario. She happily reveals that now she enjoys using the smartphone and laptop and never feels isolated. She admits that the crisis caused by the Covid-19 has not been easy, but she thought she survived thankfully because of social media. Right from information gathering to connecting online, she could do it all. Her son was, however, responsible for taking care of her daily needs (all in the online mode).

2. *One respondent around 70 years of age said that the Internet is the world for him even though his entire family lives with him except one son staying in another city. Explaining the importance of smartphones and Internet connectivity in his life, he said, "smartphone is like my partner and companion; I spend almost 10–12 hours a day with it doing several things." For him, connectivity was not the basic necessity during the pandemic but keeping a check on the updated situation and other protocols was his main concern, and he thanks social media for that. He believes that silver surfers like him depended on social media when the Covid-19 made the entire world stay indoors. He further clarified that staying engaged through social media has been the only way to overcome anxiety and stress issues, given the pandemic scenario, which is nothing less than a major disaster.*
3. *One 69-year-old female respondent said that she uses the Internet more for health information, which has been a blessing in the Covid-19 crisis. She said that she was not much into online buying or banking, but the pandemic has compelled her to learn both, and she has no looking back regarding dependency. She has also learned online banking and enjoys purchasing and ordering services online. This lady believes every individual, despite age, should use social media as it not only helps in socialization or extracting information about anything in the world but also is a great aide in daily lives, mainly when a crisis occurs. To support her belief, she has also taught basic mobile phone skills to her full-time house help.*
4. *Another female respondent of 67 years who was self-admittedly "mobile-challenged" a few years back now acknowledges that she is superbly computer and mobile phone friendly. She enjoys her time spent "online." She lives alone as her husband died a few years back, and her two daughters are settled in other cities after marriage. She enjoys writing and pens down any thought that crosses her mind. She admitted that she has been depending on social media for every information she realized she is responsible for her well-being, especially during the pandemic as her daughters were away. She mentioned the requirement of living healthy as she fears the idea of getting hospitalized alone. She admits that more than the pandemic, her husband's death affected her, and she felt lonely. She stepped into the virtual world to find a way out of that misery, which she adapted after some initial learning setbacks. When asked how her experience interacting with friends in the virtual space was, she replied that making friends online is much easier comparatively. However, she specifically mentioned that one must be careful in the virtual area; it depends on the mindset of whom to trust and how much information must be disclosed.*

Discussion

Based on the substantive findings, some exciting revelations can be made about how social media has made inroads into the life-world of the aged people and its relevance during a crisis. Although maintaining social contacts continues to be the primary purpose for using social media by older people, many of them now rely on virtual platforms to define their daily communications comprising sharing links, chats, photos, videos, extracting news, and updating status with their fast-growing social network and all that in increased pace during a crisis. This makes us talk about how the proper intervention can lead to improvising communication among the elderly through social media during emergencies and unprecedented situations. In the experiences shared by the older people who live alone, it has been noted that they worry about the uncertainty of being hospitalized alone or dying alone. It draws attention to the significant problem of care in the context of aging people, and it shows how the crisis in respect for the most vulnerable members of society existed even before the pandemic revealed the breadth and depth of the problems. The mental health of older adults is generally a concern, especially for those who live alone.

Another underlying tone that could be drawn from the respondents' accounts is that they have expressed how meeting their relatives, children, and peer groups have always provided them with a sense of fulfillment and security. The pandemic has changed the entire scenario and restricted their daily sources of joy. However, the larger argument is that the situation is similar for aged people and aged people are comparatively more vulnerable. There are many studies bearing testimony to this point. As anticipated, it has been found that the decreasing scope of staying socially connected has been challenging for older adults. Total restriction of social interaction among aged people has generated adverse concerns for their health, especially those with prolonged diseases and age-related syndromes. Earlier studies have validated a relationship between social seclusion and loneliness with prolonged conditions, disability, and physical inactivity in the aging population (Loyola et al., 2018).

Cultural effects on older women are also of utmost prominence. In a traditional setting in India, it is usually the wives who serve as the primary caregivers in the household. Moreover, domestic help services and other paid caregivers have been restricted by all the impositions. All of these have led to the women becoming the sole carers of the husbands and house. It is also applicable in the case of older women. For some elderly women, it eventually became a habit over a while. In the words of an aged woman (respondent), "My children are abroad, my husband is ill, my house help can't enter the home, I cannot go out, and I am not as smart as my smartphone. So practically, I am physically, socially, and emotionally distanced in all ways!" The ongoing pandemic has made older people lonelier with a feeling of helplessness, considering they are doubtful of stepping out. What has also been observed from the responses of the aging people is that reliance on information technology is not the ultimate solution for them because nothing could replace the importance of actual socializing in their age group. It was discovered that older women and men were least likely to have access to and the ability to use online

communication tools. The consulted respondents clarified that they did not want the “new normal” to exist online because that would lead to more isolation. Reduced public services, isolation, and deteriorating mental health could be the effect of the pandemic among aging people.

The government needs to be more explicit about considering the rights and needs of older persons, particularly in developing countries. During Covid-19, the narrative review has revealed that the gathering, monitoring, and analysis of data that is broken down by sex, age, disability, and location are crucial for comprehending the risk that the pandemic poses to the elderly, the discrimination, violence, and abuse that they encounter, and the various roles that they play in their families, communities, and economies that can help societies develop flexibility and contribute to the recovery process post-pandemic situations. The diversity of older people and their requirements must be recognized. An age-specific mainstreaming approach should be added to the principles identified for promoting healthy aging.

Conclusion

Instead of a conclusion, this chapter tried to establish that older people must be treated as the resource they have always been for their families, communities, and society. With the “new normal” concept emerging post-pandemic, older people should not be pushed to live a lonely life just because of their age. They must get help or appropriate support if they need to separate themselves. In conclusion, the present paper suggests that the mental and physical well-being of aging people is depressingly affected during the Covid-19 pandemic. WHO and other expert organizations have recommended keeping older people physically and mentally healthy during this pandemic. It is an essential requirement of the hour that an integrated and multidisciplinary evaluation between geriatricians, psychiatrists, and caregivers is done. Older people form a diverse group with various capacities, skills, and resources. Appropriate mediated communication may help enhance older people’s support in emergencies and disasters to minimize harm and help them maintain the highest possible health and functional capacity or fastest recovery. Thus, it could be said that in planning interventions or responses to the needs of older people during crises or emergencies, it is helpful to consider the type of support that social media could provide in increasing communication possibilities for them.

Abstract

In contemporary times conglomerates of the Hindi film industry such as Yash Raj Films, Disney UTV, Fox, Reliance Entertainment, Eros, Dharma Productions, Red Chillies Entertainment, and others are referred to as “studios” by the industry. One such prominent studio remains Yash Raj Films (YRF), a family-run private limited studio founded by Yash Raj Chopra in 1970 and run by his son Aditya Chopra. The company does film distribution in Indian as well as overseas markets. In addition, YRF also operates (as subsidiaries) through horizontal integration in allied entertainment industries like music, television, merchandising, digital, and comics.

According to the Federation of Indian Chambers of Commerce and Industry (FICCI) 2018 report, the value of the Indian Media and Entertainment Industry reached INR 1.67 trillion in the year 2018. However, COVID 19 pandemic struck this Hindi film industry in 2020 and stalled its growth. As per government regulation, multiplexes and single-screen cinema halls were shut down. As a result, film productions were also delayed for a considerable period. This chapter will attempt to gauge how the film studios, for instance, YRF, survived and

sustained during the pandemic. A collective understanding is that the industry survived with the aid of its alliance with over-the-top streaming (OTT) platforms such as Netflix, Prime, Hotstar, and so on. However, YRF had no OTT film released in 2020. Therefore, this research aims to understand how a studio like YRF survived during the pandemic times. The research will use an ethnographic method of qualitative interviews. This involves fieldwork and interviews with scriptwriters, producers, directors, actors, editors, cinematographers, production designers, and exhibitors. The interview and field visit will be an exploration of the business strategy of YRF, attempting to locate the methods and means of the survival strategy of the studio during pandemic times.

Introduction

“Bollywood,” an industrial and cultural condition of contemporary Mumbai (Bombay) cinema, has been studied often in the context of globalization and neo-liberal economic policies of the Indian state (Ganti, 2004; Prasad, 2003; Rajadhyaksha, 2003). In this context, the role of the diaspora has been argued as pivotal (Desai, 2004; Dudrah, 2006; Mishra, 2006). Bollywood has been identified as one of the many implications of the socio-economic changes resulting from neoliberal policies adopted by the Indian government during the 1990s (Punathambekar, 2013; Prasad, 2003; Rajadhyaksha, 2003; Vasudevan, 2008). Academic discourses around post-1990s Hindi cinema from Mumbai (Bombay) have widely tackled “Bollywood” with regard to the representation of the Indian diaspora (Dudrah, 2012; Mishra, 2006; Prasad, 2008; Rajadhyaksha, 2008). However, outside the ambit of diasporic engagements, scholars such as Tejaswini Ganti (2012) have taken an anthropological approach focusing on the “social world of Hindi filmmakers,” “filmmaking practices,” and “ideologies of production” of Bollywood cinema. Based on an ethnographic account, her work elucidates the changes in the modus operandi of the Hindi film industry from the 1990s till 2010. Following the same methodological approach, this chapter locates the business model of Hindi film studios in the new millennium, taking the Yash Raj Films case study (YRF). This new business model, a convergent business model, makes these studios, such as YRF, risk-free, helping them survive even during a crisis like COVID 19.

In the book *Ideology of the Hindi Film - A Historical Construction* (1998), Madhava Prasad states that from 1950 to 1970, the film industry was spread over three distinct sectors – production, distribution, and exhibition. Moreover, each of these sectors involved many individual independent entities instead of large syndicates. With the studio model of operation, the ownership patterns have altered significantly, resulting in a conglomerated industry. The vertical integration of the film business refers to the integration of critical segments like finance, production,

distribution, and exhibition (Ganti, 2004, p. 233). Thus, ideally, a vertically integrated film company would finance, produce, distribute, and exhibit its films. However, integration between any two tiers of the chain, such as production and distribution, as in the case of studios, can still be referred to as vertical integration. Horizontal integration means acquiring additional business activities in the same industry (Nelmes, 2012, p. 30). In other words, it may refer to a merger or a new business in an allied industry segment but the same stage of production. Thus, a horizontally integrated media company will not simply make films but also operate in other media segments such as television, special effects, music, home entertainment, retail, and gaming. In contemporary times, large-scale vertical and horizontal integration transpire among a few conglomerates of the Hindi films industry, such as Yash Raj Films, Disney UTV, Fox, Reliance Entertainment, Eros, Dharma Productions, Red Chillies Entertainment, and others, which are referred to as “studios,” by the industry.

Yash Raj Films (YRF) Business Model

YRF is a family-run private limited studio founded by Yash Raj Chopra in 1970 and currently run by his son Aditya Chopra (*ibid.*). The company follows a vertically and horizontally integrated model of operation. According to the company’s website, it “controls almost every part of the value chain from production to post-production, domestic and international distribution, music and home entertainment, marketing, design, digital, licensing, merchandising, talent management, brand partnerships, music studios and film studios – all in-house facilities, which makes it one of the most coveted entertainment conglomerates in the country” (See YRF website “about us” section. Yash Raj Films. (n.d). The Company. Retrieved 2016, June 17 from <http://www.yashrajfilms.com/AboutUs>). The company began with film production and then spread vertically into the distribution business, distributing in-house films and once made by other production houses. The company does film distribution in Indian as well as overseas markets. YRF also operates (as subsidiaries) through horizontal integration in allied entertainment industries like music, television, merchandising, digital, and comics (Aashish Singh stated in the interview that with the realization of the changes in traditional monetization, they decided to diversify their business). Despite being a private limited family-run company, the company operates with a corporate business structure. In this regard, Aashish Singh furthermore states:

The structure of the company is very corporate. The way we handle the business is very transparent and professional . . . Yash Raj Films is not a listed company, but it is corporate in its structure, in its behaviour, in the manner in which it conducts its business. (Aashish Singh| interview, October 21, 2014)

YRF office at Andheri Mumbai (October 14, 2014). (Personal photograph by the author inside YRF office (14th October 2014))

YRF was formed in the year 1971. Under its banner, Yash Raj Chopra made films like *Daag* (1973), *Kabhi Kabhi* (1976), *Silsila* (1981), *Mashaal* (1984), *Chandni* (1989), *Lamhe* (1991), *Daar* (1993), *Dil to Pagal Hai* (1997), *Veer-Zaara* (2004), and *Jab Tak Hai Jaan* (2012) among others (The information is retrieved from the milestone section of YRF website, which has information on all films directed by Yash Chopra. See Yash Raj Films (n.d.) YRF Milestones. Retrieved 2016, June 20 from <https://www.yashrajfilms.com/about-us/yrf-milestones>). Later his son Aditya Chopra made films like *Dilwale Dulhania Le Jayenge* (1995), *Mohabbatein* (2000), and *Rab Ne Bana di Jodi* (2008), also under the same banner (See Yash Raj Films (n.d.) ADITYA CHOPRA CHAIRMAN & MANAGING DIRECTOR – YRF Retrieved 2016, August 10 from <https://www.yashrajfilms.com/about-us/aditya-chopra>). The first office of YRF was inside an apartment in Juhu Mumbai. Its informal setting contrasts with the new corporate office in Shah Industrial Estate in Andheri (West) Mumbai (I have personally visited the new office of YRF during my field research in 2014 and recorded audio-visual material about the studio property. Mr. Sanjay Shivalkar, producer, YRF, described the old office in Juhu, Mumbai (interview| 14th October 2014)). Inaugurated in 2005, the new office has two recording theaters, a tracking suite, a film mix theater, a dubbing suite, and a Foley suite. At present, Aditya Chopra is the Chairman and Managing Director of YRF (However, as in the case of many corporates and industries, Aditya Chopra heads the group because of kinship connections). The film production unit comprises salaried employees, including writers, cameramen, and editors. In this regard, YRF producer Sanjay Shivalkar stated, “people working here are all salaried employees, all of them and not on a contract basis. There are always 4–5 films on the floor, so we always need hands” (Sanjay Shivalkar| interview, October 14, 2014). Each floor of the YRF office is dedicated to an individual aspect of the film business. The first floor houses the conference room and other office cabins; the second floor is dedicated to the business aspect of filmmaking, and the third floor to the creative element. The fourth floor is a personal office of the chairman Aditya Chopra (The said observation

has been made during my visit to YRF office in Andheri West on several occasions during my fieldwork in October 2014). Production-designer Sumit Bose (who worked as a production designer of the film *Dhoom 3*) stated, “the creative and business team of YRF itself decides the production-designing budget. The entire budget is proposed before the film goes on the floor” (Sumit Bose| interview, October 31, 2014). YRF started its subsidiary Y-Films in 2011 to make youth-oriented films and online content. It began with the production of films like *Luv Ka the End* (Ashish Patil, 2011), *Mujhse Fraaaaanship Karoge* (Nupur Asthana, 2011), and *Mere Dad Ki Maruti* (Ashish Patel, 2013). Compared to traditional YRF films, these films are youth-centric, low-budget films and lack star power (See <http://yfilms.in/>). A subsidiary of YRF called YRF Entertainment operates in Los Angeles as a Hollywood production and financing company with Uday Chopra, youngest son of Yash Raj Chopra, as the CEO (See <http://www.yrfentertainment.com>). It produced the Hollywood film *The Longest Week* (Peter Glanz, 2014) and partly financed the film *Grace of Monaco* (Olivier Dahan, 2014) (*Ibid.*).

The distribution division of YRF distributes both in-house productions and films produced by other producers/production houses in India and the overseas market. Apart from in-house productions, YRF has also distributed films like *Happy New Year* (Farah Khan, 2014), *Kabhi Alvida Na Kehna* (Karan Johar, 2006), and *Kal Ho Na Ho* (Nikhil Adwani, 2003), among others (*ibid.*). Aashish Singh states that distribution offices were first opened in London and New York, along with the release of the film *Dil To Pagal Hai*. Distribution offices in India were set up soon after, followed by a distribution office in Dubai. The studio also has sub-distributors worldwide (Aashish Singh| interview, October 21, 2014). The distribution segment of the business is a stable source of income, which reduces the risk involved in the filmmaking business of YRF. Sanjay Shivalkar stated:

YRF never loses our money. We break even... We are our own distributors. In certain films, we make 50 per cent profit and others we make 25 per cent profit. The profits get distributed evenly. (Sanjay Shivalkar| interview, October 14, 2014)

Post-2006, YRF follows the strategy of product diversification. Films like *Dhoom 2* (Sanjay Gadhvi, 2006), *Jhoom Barabar Jhoom* (Shaad Ali, 2007), *Chak De! India* (Shimit Amin, 2007), *Rocket Singh: Salesman of the Year* (Shimit Amin, 2009), *Ek Tha Tiger* (Kabir Khan, 2012), *Dhoom 3* (Vijay Krishna Acharya, 2012), and *Kill Dill* (Shaad Ali, 2014) can no longer be labelled as a single genre or category. In 2008, the studio also co-produced an animated film *Roadside Romeo* associated with The Walt Disney Company. Furthermore, there was an increasing tendency to integrate elements in the film that plays well in other media markets and the traditional theatrical market (FICCI-KPMG media and Entertainment Report 2012 states “Depending on the genre and star-cast of the film, studios can recover anywhere between 40–80 per cent of their production costs before the film is released. Rights for cable and satellite, music, home video and select merchandizing are all sold prior to release of the film in theatres. In select cases, even overseas rights are sold upfront. Reduced dependence on box office collections to recover money

has mitigated business risk for production houses and provides an upfront return for much before the actual release date" (FICCI-KPMG, 2012, p. 70)). By 2005, YRF attempted to monetize allied revenue platforms by spreading its business horizontally across television, home video, music, merchandising, publication, and digital market. For example, YRF started monetizing satellite rights with the film *Hum Tum* (Kunal Kohli) in 2004 (Sanjay Shivalkar | interview, October 14, 2014). Furthermore, the overseas market also expanded due to the setting up of distribution offices across the globe. Post-Veer Zaara, YRF started distributing indigenously across all territories and launched its home entertainment and music division (Sanjay Shivalkar| interview, October 14, 2014). The merchandising division began with the film *Fanna* (YRF sold three products showcased in the film *Fanna*, a Mirchi Pendant (worn by Amir Khan in the film), a cup-saucer set, and an autographed ceramic mug (Aashish Singh| interview, 21st October 2014)). yFX, the VFX division started in 2016, is a relatively new subsidiary but brings forth a considerable amount of revenue for YRF. At the same time, subsidiaries such as Digital and New Media envisions the future as they are already mainstream delivery platforms for a certain kind of cinema.

Key subsidiaries of YRF include the following:

- Film Production: YRF produces 6–7 films annually.
- Film Distribution – India: Apart from home productions, YRF also distributes films solely as a distributor across Indian territories.
- Film Distribution – International: Apart from distributing home productions, this subsidiary also distributes films outside the YRF banner in international territories.
- YRF Studio: It comprises the fully equipped shooting floor that YRF uses for home production and renting purposes. The shooting floor has three sound stages, a vertically integrated array of film services and technically trained staff.
- yFX: Started in 2016, yFX is the VFX division of YRF. Its ambit of VFX work includes 3D asset build, animation, matte painting, compositing, and visual effects. Once again, as in the case of all other subsidiaries, it manages both home production and offers its services to other production houses.
- YRF Entertainment: This new subsidiary makes OTT content for YRF. It has announced its first OTT series, *The Railway Men* [Unreleased], in 2021.
- YRF Home Entertainment: YRF Home Entertainment distributes and markets DVDs, VCDs, and Blue Ray Discs and recorded music in the United Kingdom, the United States of America, the United Arab Emirates, and India. Under the title Forever Classics, YRF home entertainment acquired and released several classic films from external banners like R.K films (R.K Chopra films) and B.R films (B.R Chopra films).
- YRF Music: This subsidiary of YRF markets and distributes its music through its label YRF Music. It started its operation in 2004 with films like *Hum Tum* (Kunal Kohli, 2004) and *Dhoom* (Sanjay Gadhvi, 2004) in the overseas market. YRF launched its music label worldwide with the music of the film *Veer Zaara* (Yash Chopra, 2004). It furthermore continued its operation with films like *Bunty Aur*

Bubli (Shaad Ali, 2005), *Salaam Namaste* (Siddharth Anand, 2005), *Neal n Nikki* (Arjun Sablok, 2005), *Dhoom 2*, *Fanna*, *Chak De India*, *Jhoom Barabar Jhoom* (Shaad Ali, 2007), and *Ta Ra Rum Pum*. It has also released music albums of artists like Rabbi Shargil (*Avengi Ja Nahin*, 2005) and Ali Zafar (*Jhoom*, 2011).

- Merchandising: The merchandising division of YRF was launched in 2013 and sold merchandise related to all upcoming YRF films.
- Licensing: YRF has a vast repertoire of films, audio-visual, and music content, which holds exclusive copyright. The Licensing division monetizes this content by selling licenses to all possible delivery mediums such as television, radio, OTT, etc.
- Digital and New Media: This is the new distribution segment of YRF which only deals with the distribution of YRF content to online streaming platforms.
- YRF Talent: It is the talent management division of YRF.

These subsidiaries make the company a horizontally integrated organization with multiple stakes in allied media industries such as home entertainment, television, music, publishing, and merchandising.

The OTT Myth

India's increasing Internet penetration and the government Digital India initiative fuelled the OTT (Over the Top) consumption in India. The exact reflection is visible with the rising growth of India's online broadcast sector. These online content providers also referred as OTT platforms include names such as ALT Balaji, Eros Now, Voot, JioCinema, MxPlayer, Hoichoi, Sun Direct, and Zee5 and international providers such as Disney+ Hotstar (formerly Hotstar), Netflix, Amazon Prime, Viu, SonyLIV, and AppleTV+. Conversely, there was also a steady rise of OTT subscribers in India. The IBEF report stated that OTT video subscriptions increased by double and reached 62 million in 2020 from 32 million in 2019 (IBEF, 2021).

The pandemic hit the country during 2020, with lockdowns imposed nationwide. Most film productions halted during the pandemic, and the most significant blow to the Hindi film fraternity came with the pan India closing of single screens and multiplexes. With a complete shutdown of the theatrical film release, producers and distributors had to resort to OTT as the key delivery platform during the pandemic scenario. The bandwagon started with the OTT release of the film *Gulabo Sitabo* (2020), directed by ace director Shoojit Sircar, and casting big stars like Amitabh Bachchan and Ayushman Khurana. The film was initially supposed to be a theatrical release; however, the theatrical release differed indefinitely due to the pandemic. The film producers Ronnie Lahiri and Sheel Kumar struck a deal with the OTT platform Amazon Prime and released the film in the OTT first mode (Previously the practice in the Hindi film Industry is to release a film in an OTT platform approximately 8 weeks post its theatrical run). Media reported that the film made with INR 40–45 crore budget recovered INR 60 crore with the OTT first Amazon Prime Video deal. However, the Multiplex chains in India like PVR

Cinema, INOX, Carnival Cinema, Cinepolis, etc. condemned the act. INOX India released a statement in response to OTT first mode. The report stated:

Inox would like to reiterate that as the backbone of the cinematic value change, this [theatrical] windowing pattern has done wonders in terms of revenues for the content creator and all other stakeholders, as it offers the opportunity to extract the best from all available mediums which include cinemas, OTT platforms as well as satellite. Inox would like to urge all content creators not to skip the theatrical run and stay with the age-old established windowing pattern, which is in the best interests of all stakeholders in the value chain. (Inox Leisure Ltd, 2020)

Followed by the film *Gulabo Sitabo*, films like *Shakuntala Devi* (Anu Menon 2020), *Laxmi Bomb* (Raghava Lawrence, 2020), *Dil Bechara* (Mukesh Chhabra, 2020), and *Sadak 2* (Mahesh Bhatt, 2020) were all released first on an OTT platform making the trend of OTT first a customary practice among film producers. The OTT release became lucrative for small- or medium-budget film with theatrical release facing a complete shutdown. OTT guarantees a specific revenue pre-release, therefore de-risking the film, which is not the case for theatrical revenue. Theatrical revenue is dependent on box office success. However, this OTT first mode was viable primarily for low- or medium-budget films. This was because currently, OTTs are not able to compensate big-budget films and make OTT first model financially rewarding for them.

Furthermore, blockbuster films earn considerable revenue from overseas theatrical rights, and OTT first release would mean a zero-revenue earned from selling overseas rights. For example, blockbuster films *Sooryavanshi* (Rohit Shetty 2021), *83* (Kabir Khan 2021), and *Radhe* (Prabhu Deva 2021) all had theatrical releases despite COVID 19 continued restrictions. As per media reports, the producers of the film *Sooryavanshi* held back the film's release for 2 years to have a theatrical first release. For a big-budget Hindi film with a budget of INR100 + crore the OTT revenue alone cannot guarantee complete recovery. A big-budget film must resort to multiple revenue platforms and accumulate profit from various sources by selling overseas rights, telecast rights, streaming rights, merchandising rights, etc.

A studio like Yash Raj Films, Disney UTV, Fox, Reliance Entertainment, Eros, Dharma Productions, and Red Chillies Entertainment functions differently from a stand-alone production house. Out of many other production and distribution houses based in Mumbai like Aamir Khan Productions Private Limited, Rajshri Productions Pvt. Ltd., Percept Pictures, Red Chillies Entertainment Pvt. Ltd., and Shree Ashtavinayak Cine Vision Ltd., only a few production houses are defined as "studios." Yash Raj Films, Viacom 18, Disney UTV, Fox Star Studio, Reliance Entertainment, and Eros International are "Tier 1" studios, and Times Group, Balaji Motion Pictures, and Excel Entertainment are "Tier 2" studios (Aditya Krishna interview, October 21, 2014).

One defining feature of any studio is that they distribute films not made in-house. The distribution of films is a significant source of revenue, which gives studios a greater extent of flexibility and de-risks the filmmaking business. Another defining feature of a studio is that all studios have a vertically and horizontally integrated

business approach. Therefore, studios function as corporations, where capital from one division can be invested in the others. Furthermore, the horizontally integrated business approach allows the monetization of the content (film) across media subsidiaries such as television, home entertainment, music, gaming, merchandising, and Internet content creation. This phenomenon de-risked the filmmaking business in India under the aegis of studios. This De-risk formula allows the studio to take more significant risks, make big-budget films, and recover costs by monetizing the content (film) across delivery platforms.

During the pandemic crisis in 2020, several studios also resorted to producing the small-budget film, selling their films to OTTs with the first OTT release model. However, such numbers are less with few films like *Chhapaak* (Meghna Gulzar, 2020), *Panga* (Ashwiny Iyer Tiwari, 2020), *Shikara* (Vidhu Vinod Chopra, 2020), and *Dil Bechara* (Mukesh Chhabra, 2020) produced by Fox Star Studio, *Shimla Mirchi* (Ramesh Sippy 2020) produced by Viacom18 Motion Pictures, *Bhoot – Part One: The Haunted Ship* (Bhanu Pratap Singh 2020) and *Gunjan Saxena: The Kargil Girl* (Sharan Saxena, 2020) produced by Dharma Productions, and *Kaamyaab* (Hardik Mehta 2020) produced by Red Chillies Entertainment. However, most studios, including Yash Raj Films, had no film releases in 2020. In 2021 Yash Raj Films released its film *Bunty Aur Babli 2* (Varun V. Sharma 2021), YRF's first post-COVID release theatrically in November 2021, followed by its OTT release on Amazon Prime Video in December 2021.

YRF Survival Strategy

In the year 2020, YRF did not produce any films. However, its vertical distribution division distributed two films this year, produced by different production houses – *Jai Mummy Di* (Navjot Gulati, 2020) and *Malang* (Mohot Suri, 2020). *Jai Mummy Di* is a co-production by two production houses, Luv Films and T-Series Films. After that, Yash Raj Films joined hands merely as a distributor. For *Malang*, Yash Raj Films entered a deal with the production house Luv Films and was solely involved in the film's worldwide distribution. However, both films were pre-pandemic and were released in theaters. Nonetheless, these films being only distributed by YRF (with no role in production) is an instance of how YRF derived revenue for the company despite not producing a film of their own in 2020.

YRF earns considerable revenue from film and music royalties. The very idea of YRF Home Entertainments and YRF music was launched on this same idea. YRF wanted to make revenue by re-running its old films and music systematically. Year on year, YRF earns a considerable income from royalties from old films and music. In 2019, YRF had to face court proceedings because of not paying royalties to the amount of 100 crores to artists. The amount is indicative of revenue sourced by YRF from the Home entertainment and music division of its company. In 2020, YRF partnered with leading multiplexes, including PVR Cinema, INOX, and Cinepolis, to screen iconic YRF films such as *Dilwale Dhulhaniya Le Jayenge*, *Dil to Paagal Hai*, and so on.

YRF also earned considerable revenue by selling satellite rights of his unreleased films in the year 2020. In addition, it made new alliances with Disney+Hotstar as its OTT partner to showcase YRF's old films. In contemporary times, satellite and digital rights bring considerable revenue to the production house or the distributor (or both), depending on who owns the rights. YRF, during the year 2020, signed deals with streaming platform Amazon Prime for the digital release of 2021 slate of films. It is primarily because of YRF Tire 1 Studio status that such deals are manifested pre-release, which becomes instrumental in the survival of a studio like YRF during the pandemic. In 2020, YRF also geared up to start a new business venture, wherein it will create its streaming platform called YRF Entertainments with an approximate 500 crore investment.

With the pandemic hitting the film industry, a studio such as YRF, instead of laying off employees, came forward to help lower economic group daily film workers. It started a foundation in the name of its founding member – Yash Chopra Foundation – which became the sole instance where a studio came forward to support workers who during pandemic, because of stalled film productions, could not find any work and therefore perished. The foundation credited money directly to workers bank accounts, enabling their survival during the pandemic period. However, YRF studio remained functional during the pandemic barring the lockdown days. In the case of the year 2020, YRF home production films like *Shamshera* (Karan Malhotra) and *Pathan* (Siddharth Anand), both unreleased as of July 7, 2022, were being shot at YRF studio. Though the shooting of the film *Shamshera* was stalled due to lockdown, approvals were taken right after from the Producers Guild of India, and shooting resumed, albeit taking all precautionary measures. Alongside YRF studio, the VFX division of YRF was also functional during the pandemic, where a considerable amount of work was also being perused from home. Therefore, during the pandemic, YRF was continuously operational, working on the slate of forthcoming films, which were scheduled to release after the pandemic, such as *Shamshera* and *Pathan*. Thus, unlike smaller production houses, a studio such as YRF was well equipped to sustain a crisis such as pandemic. This is because, unlike a small production house which produces one film at a time, a studio such as YRF always has a slate of films. YRF usually releases 7–8 films annually (as co-producers, distributors, or both). Some films are made in-house; others are financed (term used is co-produced); for some, the role is restricted to distribution only. An extensive portfolio of films under the banner ensures that the risk is diversified.

Conclusion

Conglomeration Is a De-Risk Strategy

A vertically and horizontally integrated finance, production, distribution, and exhibition model, like in the West, is setting its footsteps in Bollywood especially following the entry of Hollywood production companies in the new millennium. A very few integrated conglomerate players, most having foreign collaborations, own a

majority share of the industry. Large-scale vertical and horizontal integration transpire among few conglomerates such as Yash Raj Films, Disney UTV, Fox, Reliance Entertainment, Eros, Dharma Productions, Red Chillies Entertainment, and others referred as “studios” by the industry. One such conglomerate is Yash Raj Films. There are sixteen subsidiaries under the banner of YRF films, making it an entertainment conglomerate of the Hindi film Industry.

Studio such as YRF functions as a corporation, where capital from one division can be invested in the others. The distribution of films is a significant source of revenue, which gives studios a greater extent of flexibility and de-risks the filmmaking business. The distribution of films not being limited to one territory, country, or media platform, YRF has distribution offices all over India, Dubai, the United States, and the United Kingdom. They also sub-distribute films worldwide (Aashish Singh| interview, October 21, 2014).

Furthermore, the horizontally integrated business approach allows the monetization of the content (film) across media subsidiaries such as television, home entertainment, music, gaming, merchandising, and Internet content creation. This phenomenon de-risked the filmmaking business in India under the aegis of studios. A studio usually releases 8–10 films in a year (as co-producers, distributors, or both). Here, losses incurred from one film can be recovered from the profits of another. Thus, to some extent, studios such as YRF are more likely to escape the impact of any crisis such as the COVID 19 than the individual producers, who are more susceptible to such risk.

Abstract

In contemporary times, massive industrialization, resultant pollution, and exorbitant population growth including various other myriad reasons have led to drastic climatic changes and a spike in natural disasters. In such situations, media forge a direct link between the public, administration, and emergency services in reportage and information dissemination pertaining to disaster management, preparedness, and response. This research paper aims to explore information about media coverage in the Union Territory of Jammu and Kashmir in response to 2014 massive floods.

In the aftermath of this disaster, it damaged the region's infrastructure, snapped electricity, destroyed communication network for months, and ruined business sector worth millions, affecting every section of society in the Kashmir valley in multiple ways. In such a situation, the role played by media in disaster reporting presents an interesting area of study. This study was conducted to analyze the "agenda setting role" of the media with a focus on the leading media narrative at regional, national, and international level to understand the overall media portrayal. The analysis was drawn using content analysis and bring to the fore, social

and political realities. The findings reveal important implications for the understanding of media and political narrative in the backdrop of the long-standing Kashmir discourse and the role of media.

Keywords

Kashmir floods · Disaster reporting · Agenda setting · Media narrative

Introduction

Media is considered as the most dominant source of information by which we gain information on different crises of the world around us. Apart from reporting on contemporary political and socio-economic issues, media also reports on various disaster situations. Media activism is very prominent in the wake of any calamity or disaster. It not just informs but generates discourses, questions, or criticizes. Media treatment to issues of environmental is visible at regional, national, or international levels. The role that media can play in times of hazards includes raising awareness about the emergencies warnings, its dissemination, and details of hazards about its impact including physical, economic, social, psychosocial, etc. Journalists usually collect data from multiple sources about damage, destruction, and causalities when everyone around is confused and not clear about the situation.

Jammu and Kashmir has been the center of national and international attention since 1947, when the British gave up their century's old control over the Asian subcontinent, and simultaneously divided the region into India and Pakistan. The seven-decade-old conflict in Kashmir has witnessed some landmark news-events and political developments that received attention across the globe. But at the outbreak of the September 2014 floods in the region, more space and coverage was allocated to the Kashmir, thus setting an agenda for public debate and discussion. Media organizations from regional, national, and international level presented contesting versions of this devastating calamity. Thus it can be argued that news media's treatment of disasters largely depend on the role of the media. On an issue like Kashmir conflict, media acts as a focal point and creates public opinion thus shaping not only politics, but also basic thinking impacting issues like disaster reportage.

Understanding Kashmir Floods

Kashmir Valley is located in the northwest Himalayan region. It is embedded by the mountain ranges with Zanskar on the northeast side and Pir-Panjal on the southwest end. A distinguishing feature of the Valley is the presence of river Jhelum which stretches over the entire Kashmir valley from Verinag in south up to Wular Lake in northwest. Interestingly when river Jhelum exits from the Wular lake, it then enters into Pakistan. According to Bhat and others (2018), the maximum topography of the

valley is precipitous, which is exposed to frequent inundation especially during extended hours of precipitation, thus making more than 5.5 million people living in low-lying areas prone to multiple geographical hazards, including floods.

One such disaster which is taken as the subject of this study for the present research is the 2014 floods in Jammu and Kashmir. This disaster was by far the most serious natural disaster in contemporary history of J&K. On seventh of September 2014, flash floods caused due to continuous 7-day heavy and unprecedented rainfall washed away everything from everywhere, causing large-scale panic and anxiety in the region. The intensity of floods was such that it engulfed the whole land mass into a water body with most habitation submerged. According to media reports river Jhelum was flowing around 5 to 6 feet above the danger mark in Srinagar and Anantnag districts with the discharge rate of $70,000 \text{ m}^3/\text{s}$ against the normal discharge of $25,000 \text{ m}^3/\text{s}$. According to Fayaz (2014), the worst disaster recorded in over 50 years left 280 people dead, damaged the region's infrastructure, snapped electricity cables, destroyed communication links, and business losses amounting to an estimated \$US6718.583 million. As compared to Srinagar, floods do not affect much in Jammu division; however, there have also been incidents of landslides, damaged roads, collapse of some bridges, etc. in the region. The Prime Minister of India, Narendra Modi, on the one side at that time called the incident as national calamity while on the other side rejected foreign aid to Kashmir.

During the devastating floods Kashmir valley remained cut off from the rest of the world as all essential services remained closed for days. The situation in the valley got little tense when various media houses based in New Delhi began to airdrop their journalists in the valley to cover the floods, but despite showing actually the tragedies on ground, it remained confined with the political and security prism only. All the national channels only provided the space to the rescue efforts of Indian security and did not give enough and expected coverage to the local suffering and efforts. In this context, Hafsa (2014) revealed that militarized coverage of the floods by India's national media increased the anger of Kashmiris. They also accused the Indian army of prioritizing its relief operations – focusing on rescuing the families of military personnel, the politically influential, and Indian tourists visiting the region.

Whereas International media coverage was far more objective, it included representations of all actors involved in the flood relief efforts, including local Kashmiri people. The reporting also included a balanced political context of the ongoing conflict in the region. Local media which started publishing news 18 days after the flood presented a different picture of the overall scenario. They significantly featured the efforts of local population, self-help groups, community-services, relief camps, and other sections of the society for their brave acts in saving many lives through ways of rescue operations and with aid food and shelter for flood victims. Although these contrasting narratives did not lead to any serious form of agitations as compared to previous years from 2008, 2010, and 2016 when serious mass unrest was reported in the region but somewhere the socio-political framing of floods created a trust-deficit among the people of the valley with New Delhi in response to treatment and mainstream coverage of the Kashmir floods.

Hence it can be argued that media coverage of the 2014 Kashmir floods was not without any agenda. Therefore, the aim of this study is to analyze the portrayal of Kashmir floods in the backdrop of agenda setting theory in the selected sample of print media sources from local, national, and international perspective. It is important and pertinent to analyze and compare how newspapers focused on different phases of Kashmir floods, discussed responsibility issues, and used positive or negative tones with different framing techniques to influence both public opinions and disaster-related policies.

Media and Disaster Reporting

Media as the fourth pillar of society has a key role in building public awareness and information about all vital aspects of any disaster. Disaster and its reporting are classified by the nature of media treatment which usually depends upon the purpose and contents, for example, responsibility, sustainability, etc. For example, 2004 Indian Ocean Tsunami and 2010 Haiti Earthquake showed that media can have both positive and negative effects.

If we look at the historical perspective regarding media and disaster, National Research Council in February 1979 organized the first awareness workshop in the USA on the theme of media and disasters. Whereas the first official report entitled *Disasters and Mass media* was published in 1980 by National Academy of Science. The report was the first attempt which tried to focus on the role of mass media during disasters.

Whenever any disaster-related incident happens, it is always the local media which is considered as the primary sources of awareness and information as compared to the national and international counterpart. In this context, Liu's (2010) study revealed that, during any disaster people living in remote communities and geographically diverse locations with no access to internet are solely dependent upon traditional media sources for information regarding disasters. Further, media treatment of disaster is also influenced by the various socio-political actors to divert the attention towards a particular agenda or opinion. Therefore, the role of media in terms of understanding of disaster, its reporting, and use of language becomes all important. Van Belle (1999) in his work states that media coverage often influences agenda setting through public and political demands for disaster relief and reconstruction efforts. Similarly, Zaheer (2016) reports that agenda-setting role of media may divert the attention of government and public to emergency response and relief distribution and may ignore the more important phases of preparedness and mitigation. However, Joseph Scanlon and Alldred (1982) argued that, in many disasters, it was observed that media remained focused on the single story event such as the coverage of 2005 earthquake in Pakistan, ice Storm in Ottawa, Hurricane Katrina in the USA, and fires in Russia.

However on the flip side rather than being sensitive, responsible, and represent credible information, media has also been criticized for its insensitive coverage and exaggeration for giving unwanted importance to some issues as during the Nepal

earthquake (2015) and Uttarakhand floods (2013) to mention a few. Further one of the main parameters of media that mainly affect disasters is the competition among media houses to grab the attention of its audiences towards the discourse. While on one hand there are so many factors associated with the reporting of disaster, on the other hand journalists as a part of society also face various pressures and pulls while reporting for disasters.

During any disaster situation, media organizations are also in competition with one another in breaking news and producing a unique narrative of the disaster to generate larger public attention, readership, and advertising revenue. Besides, news sources play a significant role in news production as they have access to information which can change the course of news through their relationship with media, thus influencing news outputs and, consequently, public engagement with political institutions. The principles of objectivity that journalists follow while reporting also contribute to the multi-dimensional issues of disaster as it affects the slant of a story and its implications. Scholars like Schechter (2003) and Stromback (2005) argue that in case of any crisis situation it is exceptionally difficult to apply the traditional principles of reporting.

As per the above-mentioned arguments, the question thus arises as to which type of role the media play during a crisis which can be only determined by analyzing the patterns of media reporting, the potential constructive role of the media, how media communicated the crisis, and whether or not ethical standards and norms of journalism were followed. Hence by understanding the different narratives of media and disaster relationship, this section of paper presents useful critical frameworks on how media contribute to disasters and how disasters shape the media treatment.

Review of Literature

Disaster of any kind be it natural or man-made like floods, earthquake, plane crash, building collapse, tsunami, etc. needs quick response and instant efforts to coordinate the emergency services. Such coordination requires immediate and real-time information within and between different organizations for an efficient disaster management for the larger welfare of society. This literature review focuses on the role of communication in disaster management by analyzing the previous studies in perspective of floods only.

Khumairoh et al. (2021) in their study “The role of communication as the disaster risk reduction in Indonesia capital city transference policy” described the role of government in preventing people to face the dangers of natural hazards, disasters, and conflicts through the effective communication. The result of this study shows that disaster communication can play a major role in helping the government to share the information to the society in order to sustenance the disaster risk reductions. Similarly, Malik and Hashmi (2020) in their study entitled “Flood Realities, Development Faults and Perceptions-Natural and Anthropogenic causes of 2014 Flood in Kashmir” argue that 2014 floods in Kashmir Valley were greatly caused by the anthropogenic causes ranging from unplanned urbanization to poor developmental

policies, encroachment on Jhelum flood plain and lakes, ill-conceived dredging, human greed, breaching of dikes, and a neglected history.

In conflict areas like Kashmir, reporting of the disaster interpreted the intended political realities, thus revealing how disasters can be politicized by media to suit the interests of the warring parties in contested zones. Wasim Khalid (2015) conducted a comparative research into how the media framed stories to cover the realities of flood disaster in Kashmir. In his study "Media Propaganda and the Kashmir Dispute: A Case Study of the Kashmir Floods," the author aims to analyze whether the coverage by the New Delhi-based media was mere propaganda for the army or objective reporting of the disaster. The findings revealed that there was a lot of difference between the media reporting of two regions. The author concludes that the national media's coverage of the 2014 floods in Kashmir, its reporting, was biased and subjective as it was clear from the content analysis that reports of the disaster by the Indian national media rarely represented the local, Kashmiri point of view.

Drawing on qualitative interview evidence from 50 flood victims in south, central, and north Kashmir, Venugopal and Sameer (2017) in their study entitled "Natural Disasters amidst Political Crisis: The 2014 Flood in Kashmir" examine the role of the state and central governments, the army, local volunteers, and the media. The authors conclude that floods have in a sense provided Kashmiris with further evidence to confirm three widely held beliefs. Firstly, the floods provided evidence that the state government is ineffective and that the central government does not prioritize them. Secondly, it confirmed widely held perceptions that the Indian media is hostile to them, that it willfully distorts the reality of what happens in Kashmir. Thirdly, it reinforces the belief that their safety and well-being rests within elements of Kashmiri society itself.

Deliberating about the challenges that news correspondents face while traveling in a disaster-affected zone to gather and transmit news and information from there, Mishra (2021) in his study "Challenges of News Gathering in a Disaster Zone: A Study of Jammu and Kashmir Floods" argues that, at a broader level, the outflow of credible information from a given disaster zone is largely conditioned by the ability of news correspondents to access and gather critical information in a disaster zone which can help direct relief and rescue operations in the right direction and also strengthen them.

Kuppuswamy (2017) in her study entitled "A Study on the Print Media Coverage of Disasters" analyzes print media coverage of Vardah Cyclone of 2016 in Tamil Nadu in two leading national and regional newspapers. The author in her study argued that media frames found in the newspapers were responsibility, economic consequences, human interest, and recovery. National newspapers were responsible in giving worthy news in all the phases of disaster management whereas regional newspapers had a good coverage of news before the disaster and during the disaster. Media act as mediators between public, affected people, and civic authorities during any disaster.

In this context Das (2020) in her study entitled "Media and communication in times of crisis: Case study of Pune flood, 2019" focuses on one such crisis situation that occurred in Pune city, in the Indian state of Maharashtra. The study concludes that media plays a significant role in covering a natural disaster in regard to public

interest. It has a wider reach and informs the actual intensity of a crisis situation. From the audience perspective, the study infers that readers need to understand that there are certain constraints of the media too as media faced all odds for spot reporting or get stories from the affected area.

Research Design

A research objective must be accurate, result-oriented, and achievable; so that it must be completed within available time, infrastructure, and various other research resources. Hence based on present research study, the objectives drafted are as under:

- What has been the nature and extent of news coverage given to Kashmir floods.
- To analyze the audiences negotiation during the crisis situation.
- To compare the leading narratives presented by selected newspapers in their coverage.

The study seeks to explore and understand the nature of print media coverage given to 2014 Kashmir floods. In this research, the event-specific coverage by print media was studied using elaborate content analysis for making inferences about how media construct Kashmir floods. Furthermore, within the context of sampling, the researchers have taken only those selected sample of newspapers into consideration which are published on daily-basis and in English text. Moreover, as it was not practically possible for the researchers to study all the daily based newspapers, therefore a representative sample of newspapers were selected, from local, national, and international perspective and within which selected number of stories were analyzed and interpreted based on the need and demand of the present research study. Moreover in order to gauge how audiences negotiate with different sources of information, an online structured questionnaire was circulated among selected professional audience to record and analyze their responses during Kashmir floods.

Data Interpretation

For the purpose of this study, the researchers undertook a selected number of articles pertaining to the coverage of the Kashmir floods for analysis from the local, national, and international newspapers. The time frame for this study was taken three weeks after the incident took place, i.e., from September 7, 2014 to September 27, 2014.

Based on stratified sampling, a representative sample of 15 news stories was chosen from each stratum (newspaper) with an equal size of the sample from each newspaper. The international media took a while to respond to the floods, so their coverage started a few days later and lasted until September 20, 2014. In this context, selected sample of stories from the *New York Times*, *The Times of India*, and *Greater Kashmir* was chosen. The news stories were selected on a random sampling basis

Table 1 Representation of stories used by newspapers during 2014 Kashmir Floods

S. no	Number of stories	Sources
1	15	International media
2	15	National media
4	15	Local media
Total	45	

Table 2 Themes used during the 2014 Kashmir Floods by newspapers

S. no	Themes	International		National		Local	
		No.	% Age	No.	% Age	No.	% Age
01	Health	07	35	03	15	05	25
02	Human interest	07	35	04	20	12	60
03	Politics	05	25	10	50	03	15
04	Others	01	05	03	15	0	0

with Kashmir 2014 floods as the main characteristics. Hence, a total representative sample of 45 stories was generated from all 3 newspapers (Table 1).

The results pertaining to the thematic representation on which the stories were reported by the selected print media sources, the results revealed that the *New York Times* in its coverage of the Kashmir floods has mostly covered stories about human interest angle (35%), health perspective (35%), and politics over the floods (25%). And in comparison, *The Times of India* has dominantly used the political framing perspective (50%), human interest (20%), and health (15%) in its reportage of the Kashmir floods. Whereas *Greater Kashmir* has portrayed a completely opposite picture, it has used human interest (60%), followed by health (25%) and politics (15%), in its portrayal of the 2014 Kashmir Floods. The results also indicate that among all newspapers, *The Times of India* has used the political perspective of floods to a larger extent than others, and only *Greater Kashmir* has a maximum number of stories under the human-interest category. Further, international media responded to the floods as per the nature of the news treatment and provided a balanced view to all the themes as the events unfold (Table 2).

Sources play an important part in making a story more reliable, objective, and balanced. In this context, during the analysis of selected stories from all the newspapers, the researcher also finds it very pertinent to identify the sources that have been used in reporting to 2014 Kashmir Floods. The study found that in a maximum number of stories from the *New York Times* and *The Times of India*, 40% and 44%, respectively, have been reliable on official sources mostly. The data regarding the international media coverage further reveal that it has also provided a good amount of space to other important sources with 28% to eyewitnesses and 20% to victims of floods. Similar types of results are being recorded from the national media perceptive with 20% each to eyewitnesses and victims of floods. However, located on a national prim, the coverage could have been more balanced with more space given to different sources. In the context to *Greater Kashmir*, the results further reveal that 40% of the stories have used eyewitnesses, 28% have provided space to victims, and

Table 3 Types of sources used by newspapers during coverage of Kashmir Floods

S. no.	Sources	International		National		Local	
		No.	% Age	No.	% Age	No.	% Age
01	Official	10	40	11	44	06	24
02	Eyewitness	07	28	05	20	10	40
03	Victims	05	20	05	20	07	28
04	Anonymous	03	12	04	16	02	08

Table 4 Sources of information used by masses during Kashmir Floods

S. no	Sources of information	Number	Percentage (%)
1	Newspapers	10	17
2	Online	24	40
3	Television	08	13
4	Radio	06	10
5	Word of mouth	12	20
Total	60		

the remaining 24% to official versions of sources. Hence evident that select newspapers have provided space to all the important perspectives during the 2014 Kashmir Floods (Table 3).

The data on the information negotiation by the audiences during Kashmir Floods revealed that the majority of the population, 40%, used various online platforms as their sources of information. Besides only 17%, 13%, and 10% of the respondents used other traditional tools of information which include newspapers, television, and radio, respectively. Further, when the respondents were asked how they access the internet, the majority of participants, 70% of the sample among those who have internet access, preferred smartphones both before and after the floods for their information means. The reason for the same is attributed to its portability and availability of internet facilities at any time without much interference.

One of the interesting observations that came to the fore was that 20% of the sample revealed the word of mouth as their preferred means of information during the floods. This includes those respondents who have limited access to other major informational mediums and consider word of mouth as a reliable source of information (Table 4).

Social media played an important role in facilitating various emergency responses at all stages of any disaster and distributing information among the masses in a limited amount of time. In this regard, our findings revealed that social media play a crucial role in the context of Kashmir floods as 70% of respondents collectively consider social media as mostly used in many ways as it helps in connecting people together and is highly used in any crisis situation to remain updated and act accordingly. The data further reveal that 13% of the masses consider that the dominant use of social media sites has facilitated the propagation of messages during a disaster which also facilitates the rapid diffusion of rumors (Table 5).

Moreover, when the respondents were asked about the overall role played by the media during the Kashmir Floods, 80% of the participants believed media coverage

Table 5 Role of social media during floods

S. no	Response	Number	Percentage (%)
1	Highly useful	16	25
2	To some extent	06	12
3	Spread rumors	08	13
4	Connecting people	20	33
5	Others	10	17
Total	60		

Table 6 Role of media played during Kashmir floods

S. no	Response	Number	Percentage (%)
1	Creating awareness	18	30
2	Sharing updates	16	27
3	Information of health and hygiene	14	23
4	Sensational	08	13
5	Others	04	07
Total	60		

helped them in various ways which include awareness, providing updates to the masses about the crisis, and distribution of information about health and hygiene. The data also revealed that 13% of the respondents believe that the media sensationalize the incidents of disaster. Such type of reportage was mostly seen within the National Media Coverage of Kashmir Floods where the newspaper carried details that were misreported and only focused on the operations of army forces. Such type of coverage included exaggerated or sensationalized stories, which can turn the attention of audiences away from emergency relief and response (Table 6).

Besides when the respondents were asked about the possible role of the government during the 2014 Kashmir Floods, only 33% of the respondents supported the argument whereas another 30% consider that government did not play a pivotal role during the floods and the remaining 17% were unable to respond toward the given statement. Kashmir floods in 2014 created havoc across. During any disaster, the primary role of the government is to address all the important aspects of risk management. During the Kashmir Floods, the inability of the government to control the damage caused by the flood was evident due to the lack of proper disaster management facilities. As the rescue operation is not led by anyone because there is not any communication between officials with no means available to people to contact anybody in the government (Table 7).

Media also assists in disaster management by educating people, warning about hazards, information about affected masses, informing concerned officials, highlighting public needs, and also loopholes in government's disaster schemes and its management. In order to gauge the audience's response to whether media reportage of floods helped the government to implement disaster management plans, 36% of the sample supported the argument whereas 13% of the respondents believe

Table 7 Do you believe government played an effective role in handing the crisis

3	Facts based	16	27
4	Research based	10	17
5	Others	03	05
Total	100		

that media coverage does not help in disaster management planning. The remaining 34% of the sample was unable to respond to the given statement (Table 8).

The media are essential for warnings to be effective and are the most important source of public information in the wake of any disaster. In this context, when the respondents were asked about their stories of interest, mixed types of responses were recorded. 31% of the sample believed that they are interested in those stories which are related to the cause of floods, whereas 20% of the opinion for news content is focused on the management of floods. Moreover, 27% and 17% of the sample revealed that stories that are based on facts and research grab their interests accordingly (Table 9).

Moreover, whenever any disaster occurs, media professionals also face various pressures and challenges which also play a significant part in shaping the narratives of disasters. In this context, when the respondents were asked to put forward their responses, 27% of them were of the view that limited time space to report the disaster is the main challenge that journalists face, whereas 23% of the sample revealed that in order to meet the expectations of all sections of society is the main challenge that comes across to journalists while handling the crisis. 20% of the respondents

Table 10 Challenges for journalists

S. no	Response	Number	Percentage (%)
1	Meet expectations	14	23
2	Lack of time	16	27
3	Not sufficient disaster reporting training	10	17
4	Spot reporting	12	20
5	Others	08	13
Total	60		

revealed that spot reporting is also a major challenge that journalist face while reporting for disasters. Interestingly, 17% of the sample revealed that an average journalist often does not have sufficient disaster management/negotiation skills due to which various challenges are faced by them (Table 10).

Discussion

In the context of reporting on Kashmir floods, the international media reported on various issues. News stories from the *New York Times* were chosen as the international sample in order to understand the news coverage. The newspaper provided spaces to health communication stories, flood victims, role of local volunteers during crises, and lack of essential medicines among others. Besides media from the global perspective, also reported was how population based in Kashmir viewed the army's role in the flood. The coverage also contextualized the stories by connecting the long-standing seven-decade-old Kashmir dispute with floods by highlighting why people of Kashmir were rejecting aid provided by the Indian agencies. Besides, it also portrayed the role of volunteers during crisis and survivors of the floods.

For national media, the online archives of *The Times of India* were accessed to analyze the data. It was worth to mention here that national media decided to report on the crises when the Prime Minister Narendra Modi planned to visit the region. Until then the media from the national prism did not report a single story regarding floods, despite a wide range of stories were there in public domain generated from ground zero. It was also surprising to notice that news about Kashmir floods were not even portrayed among the top lead stories in the mainstream Indian media scenario. As opposed to international media, the coverage from Indian media was dominantly focused on the rescue operations conducted by security focusing mainly on armed forces with limited space provided to the flood management operations that were conducted by the Kashmiri populations. When the researcher looks deeply into the content of such stories, the prime focus of attention was mainly the non-Kashmiri populations. These mainly include tourists, people visiting Kashmir for work, and other non-local labors. The research findings also reveal that the Indian media did not report international aid offers that were provided to Kashmir when Indian government refused to accept foreign aid.

Besides, for the purpose of this study local media narrative was also taken into account, and in order to fulfill this purpose, *Greater Kashmir* a daily English newspaper published from Srinagar was considered. The reporters based in the Kashmir region initially reported aspects of floods that were related to its managements and possible precautions and flood damage at various places. But when the devastating floods hit major parts of Kashmir, the media persons were not able to respond and provide information to the masses. For days connectivity was snapped, and families did not hear from each other for as many as 9–10 days, leading to a virtual despair that was reflected on the social media. Journalists on the ground were only able to cover different narratives of Kashmir floods when some sort of management was done and journalists were able to move a bit from one place to another in makeshift boats.

The news stories published from the abovementioned newspaper criticized the government of India and Indian national political parties over the politics during the Kashmir floods in the name of relief and rescue operations that were undertaken by army. As compared to the other media outlets, it was mainly the social media platforms used mostly by the Kashmiris populations based in and outside valley to come together on such digital channels that became the only source of communication as and when possible as all other vital media organizations based in capital city of Kashmir Srinagar were totally submerged. After the activities resumed, the local media portrayed the real, grassroots image of Kashmir floods to the outside world. The reports presented the information while communicating the risk and act as a bridge of communication between victims and general public. The extensive reportage of role of local Mohalla communities, self-help groups, youth associations, and other sections of society in managing the crisis motivated the general public to help the victims. In case of any disaster, it's the role played by the local media by being at the ground to do spot reporting to present the actual happening. In case of Kashmir floods, it was also the coverage of local media outlets which diverted the attention of the officials, international media, and associated sectors towards the actual realities. It also diverted the attention of the government for the need assessment. The coverage also showed which agencies and authorities worked in the front line and also brought the scale of devastation of the disaster into public knowledge.

Conclusion

Media activism is very visible and prominent in the wake of a calamity or disaster. Media not just sets the agenda for proper disaster management but also reports on multiple dimensions of the issue, i.e., social, humanitarian, problem redressal, etc. In the wake of any disaster event, communication is a core component and plays a very crucial role in rescue, response, and recovery operation. As Kashmir is geo-strategically located at the intersection of India-Pakistan and China, it has attracted media attention at national and international level for various geo-political reasons. In 2014 September, a massive deluge struck Kashmir causing

damage to life and created havoc all across. It was a massive disaster leaving behind a trail of death and destruction as all communication links snapped.
